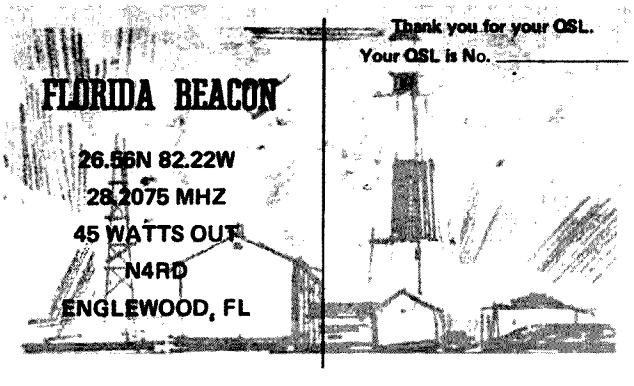
George Bailey W2KH, a communications pioneer and a former ARRL President, died in Nashville TN last December at age 89. Bailey was the first American ham to be heard in Europe on the old 5m band. Bailey was instrumental in organizing the US scientific and engineering effort for WWII. He directed the Signal Corps,



N4RD's QSL — another beacon to help predict 10m openings.

and was a founding father of the IEEE. As an amateur, Bailey was first to hear news of a sinking steamship, the *Viking*, which blew off course off Newfoundland in March, 1931. He also received first news of the Long Beach CA earthquake in March of 1933. Reprinted from the *IEEE Journal*.

One of the men who pioneered in the field of transducer design, Richard J. Billette, has died after more than twenty years of work in solid state engineering. He was 45.

Before helping to found National Semiconductor Corporation's transducer group in 1972, Mr. Billette spent one year in India establishing a technical school under the auspices of Dunwoodie Institute, Minneapolis, where he taught engineering. Prior to that, he held an influential position in the transducer activities of Honeywell's solid state electronics center in Minneapolis.

Mr. Billette held a key transducer circuit patent, and an important transducer application patent (flow meter) stemming from his work at National, in addition to a number of previous patents from Honeywell. A tireless and prolific worker, Mr. Billette was responsible for conceiving and implementing many new transducer concepts, features and applications. (Transducer devices are fairly recent electronic advances, which act as sensors to provide pressure readings and other important sense inputs for computer based systems. They have uses in many automotive, avionic and process control applications. They are said to "transform a computer into a robot," because they provide necessary external information for artificial intelligence, functioning as the "eyes," "ears," and "fingertips" of the computer.) Thanks to National Semiconductor Corporation.

Electrical storms, next to Murphy, are one of the amateur's worst enemies. Take the case of a Long Beach CA ham, as reported in the Long Beach *Independent*. "A lightning bolt struck the roof antenna of a ham radio set at the Long Beach home of Frederick Fowler. The roof and attic burst into flames. Fire Capt. Ralph Wallace said two engine companies and a ladder truck went to the Fowler home and extinguished the blaze in 15 minutes. He said Fowler

and his wife were not operating any electrical equipment and consequently were not injured, but the house 'looked like a machine gun had ripped through it.' Electrical sockets, light fixtures and a doorbell button were blown apart, Wallace said. Metal corners used to hold the plaster during construction were electrified and bent, knocking plaster all over, he added, and the concussion moved a couch several feet. Part of the cedar shingle roof and part of the attic were destroyed, with damage estimated at $6,000. Fowler's radio set, however, was unplugged and was not damaged." How many of us would be able to say the same thing if an intense electrical storm hit our home QTH? Thanks to James Ross, Long Beach CA.

There are antennas, and then there are antennas, but we'd be hard pressed to do LU7MAL one better! Mel's Mendoza diggings include the six element 20m beam pictured here, on a 65 foot boom. According to Al OA4XX, who sent along the pictures, Mel started out with separate five and seven element arrays for comparison purposes, and discovered that although he didn't gain much on the transmit side between the two antennas, the big gain was on the receive end. Ultimately a six element antenna was decided on and constructed. One of the best points about the array is the way it folds over for adjustment and tuning. What's more, the antenna can be locked up in any direction to counter high winds, a major concern in maintaining large arrays anywhere, but especially near the Andes Mountains where Mel lives. Judging by the photos, the USA does not have the only claim to the "big gun" factor in the Americas. The rig at LU7MAL is as ultimate as the antenna farm, with full legal power and a well-known signal at contest time. Thanks to OA4XX.

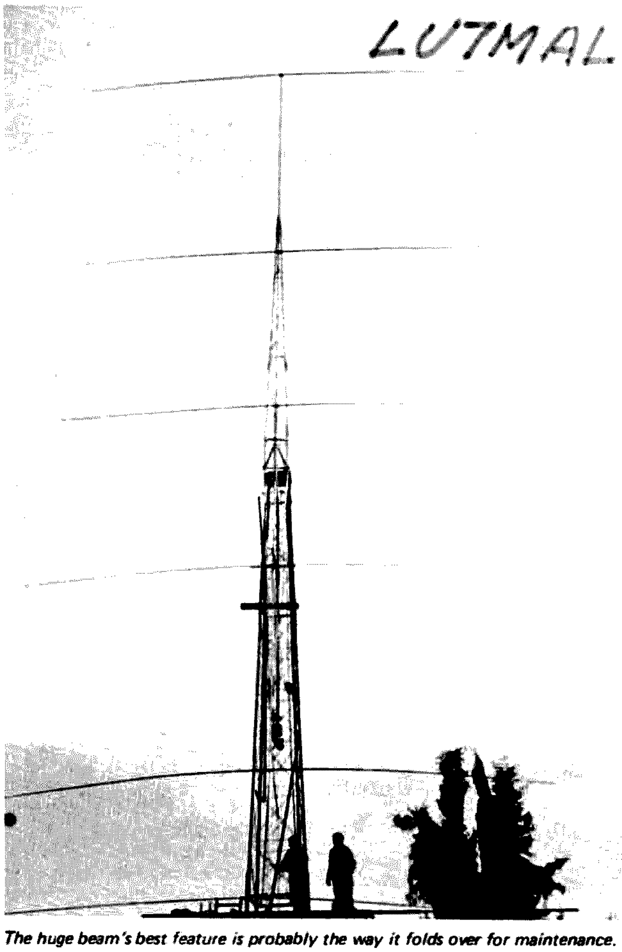
Local ham radio operators and the Coast Guard teamed up to rescue the 37-foot sailing sloop *Porsoius* when it lost steerage 25 miles off Ocean Park in the Pacific Ocean.

Lyle Clark W7RDR, Chuck Laird W7BCJ, and Jay Shepherd W7FBM combined their skills and equipment to locate the boat when it was discovered that the exact location was in doubt.

The story started when Laird and other operators were talking, using the Astoria WA repeater after a routine emergency drill on the radios.

The talk was interrupted when Bill Blaker WA6MUY, aboard the stricken vessel, called for Coast Guard assistance.

Laird set up a direct communications link with Air Astoria. The hams determined the boat's location and a helicopter was dispatched to find it.



The huge beam's best feature is probably the way it folds over for maintenance.

It was located at 12:02 am within four miles of the position determined by radio triangulation. A Coast Guard spokesman said drift could easily account for that.

Three hours later the motor lifeboat 44304 skippered by BM-2 Simonsen arrived on scene and took the vessel under tow. The 52-foot *Triumph* was dispatched, took over the tow, and just after noon Tuesday the *Porsoius* was safely moored in Ilwaco harbor.

The *Porsoius*, with three persons aboard, had a line foul the rudder, causing it to fall into the prop. The boat was dead in the water. Thanks to W7UFL (reprinted from the *Chinook Observer*, Long Beach WA).

Units of the Dallas TX County RACES played a key role in handling last February's railroad tank car explosion and fire. Within 15 minutes of the first explosion, the local net was activated and 56 units were available for crowd control, traffic duty, and communications. A command post was set up beside Dallas police headquarters, with information relayed to a half dozen police departments, fire departments and other emergency agencies. When officials thought a third rail car loaded with polyvinyl chloride might explode and spread toxic fumes, they needed to know the wind speed and direction and were surprised to find a meteorologist in the National Weather Service Office at Fort Worth monitoring the RACES net and ready with the answer. RACES personnel also manned barricades and set out flares, thus freeing many officers to return to their patrol duties. CB REACT teams also worked with the disaster team, manning barricades on the outer perimeter and urging the public to keep away via channels 9 and 19. Interestingly enough, the same Dallas County RACES group first spotted and tracked a major tornado that hit Dallas last May. Reprinted from *In the DARC*, a monthly publication of the Dallas Amateur Radio Club, Dallas TX.

The Pueblo (CO) Ham Club won some great PR with the news it would help the National Weather Service track tornadoes and other weather emergencies. An article in the *Pueblo Star Journal* reported a demonstration by the club, organized to show NWS officials 2m coverage on a volunteer basis. Fifty stations checked in, from as far away as Denver (110 miles), and the reaction was enthusiastic – the chief weather officer said he was amazed at how readily the amateurs responded to the practice alert. He went on to ask for the Pueblo club's help on a permanent basis. The club will maintain the weather watch 24 hours per day, seven days a week. Thanks to the PHC PR staff.

There's more feedback on amateur emergency efforts during this past winter's worst – WØSIN reports that the "Springs Repeater" near Colorado Springs was in action around the clock during the blizzard of late March under the direction of WØPT. A 75 meter link was maintained by KØCNV. Thanks to WØSIN.

There are two sides to every story, and the CB story is no different. The following appeared in the North Manchester IN News-Journal, *for Monday, March 18th. – Ed.*

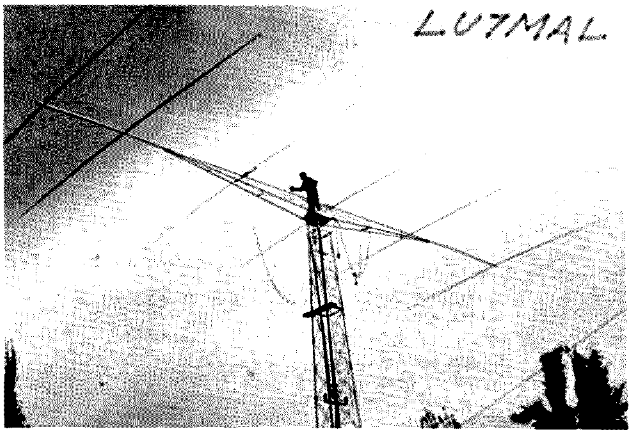
Pleasant Township Fire Department has answered its last anonymous CB fire alarm, according to Capt. Jesse Trickle of the Pleasant force.

Pleasant volunteers decided to crack down on false alarms received by CB radio after taking two false calls Friday from CBers. Trickle said the department would no longer respond to fire alarms reported over CB radio unless the caller gives his name, address, and call letters.

Friday's runs brought to seven the number of false calls received over the CB airways by Pleasant Township this year and has resulted in the wasting of over 100 gallons of gasoline as well as the time of the volunteers.

Trickle reported that Friday's calls were reporting fires on SR 15 and at the Laketon Refinery. Firemen were told that an 18 wheeler was on fire on SR 15 but nothing was found.

When firemen returned, they received another call that said the



Six elements on a 65 foot boom for 20m – that's the reason for such an outstanding signal from LU7MAL.

previous report was a mistake and there was a fire at the Laketon Refinery. Firemen went to the Refinery only to find the same thing as they had on SR 15. Thanks to WB9VKI.

A new blockbusting phenomenon is reported in certain Texas towns, where "FOR SALE" signs proliferate wherever the hated 11 meter ground plane dominates a local rooftop. Vigilante counter measures reportedly used by an aroused citizenry range from tape recording the offending transmission and giving it back to the CB neighbor via 150 Watts of stereo audio through an open 3 am window, to putting a straight pin through the offender's coax, and waiting for him to turn on his linear. Thanks WA6NCX, W6NIR, and *PAARA Graphs*, bulletin of the Palo Alta CA ARA.

The Environmental Protection Agency in Washington DC is considering a regulation to limit the height of all self-supporting towers less than 2.5 square feet (base cross section) to 34 feet.

It seems that free-standing towers experience wind shear effects which shake the towers. It also seems that, especially in the late spring and summer, this shaking is transmitted to the surrounding earth. The vibrations disturb earthworms, causing them to come to the surface (often during the hottest part of the day). Exposure of the earthworm to the sun's direct rays causes them to die from sunstroke. Earthworms are very important facets of the ecology — hence the EPA's concern. Thanks to the Cascades Amateur Radio Society *Action Mini-Mag*, Jackson MI.

Many of us dream of the ultimate station, but few of us ever seem to get that far. One who has is Ted Gamlin K1VBL of Chester NH. The photos show only a portion of Ted's multi-op setup, from the antenna farm viewpoint. Since Ted took these pictures, the winter of '77 has done its dirty work, and the big 165-foot tower (which supported a six element 20m beam and the stationmaster for Ted's 220 MHz DXalert repeater) came down. Also lost on at least two occasions was the 4 element 40m yagi, but not before the station, signing W1RR, put in a strong showing in the ARRL DX contest. Now that the warmer weather has arrived, Ted is busily rebuilding, spreading out the towers and in general beefing up the system for next winter . . . and the next contest season.

This is, of course, the Silver Jubilee of the reign of Queen Elizabeth II. And, not unlike the American Bicentennial which preceded it, the Jubilee means special calls for amateurs. A "GE" prefix is substituted for the normal one, at the individual amateur's option. The event lasts from 0001 GMT June 4th through 2359 GMT on June 12th, but it isn't being received with exactly open arms among English hams. A report in *Mobile News*, the Journal of the Amateur Radio Mobile Society, put it this way — "Obviously, if this nonsense is adopted, nobody will have a clue what country they are working. When poor Arthur Milne G2MI read this out on the 80m bulletin, he couldn't help muttering about the confusion it would cause to the QSL bureau. We can only hope that this one will go off like the proverbial damp squib, as did the American Bicentennial calls which were utterly confusing."

An FCC news release says alien hams gaining American citizenship must take the American amateur exams to continue operating. That applies even when the old license is still in effect. However, aliens will be able to keep their US calls granted initially under reciprocal agreement.

Canadians planning to operate in the US must first obtain form 410 from the FCC. Reports that current reciprocal agreements between the two countries allow "instant" operation on either side of the border are simply untrue. Operation without authorization may be in the cards in the future, however, since both the FCC and the Canadian DOC have reportedly agreed on it, but a treaty has not yet been signed. Thanks to *Transborder*, bulletin of the International Repeater Group, Fredericton NB.

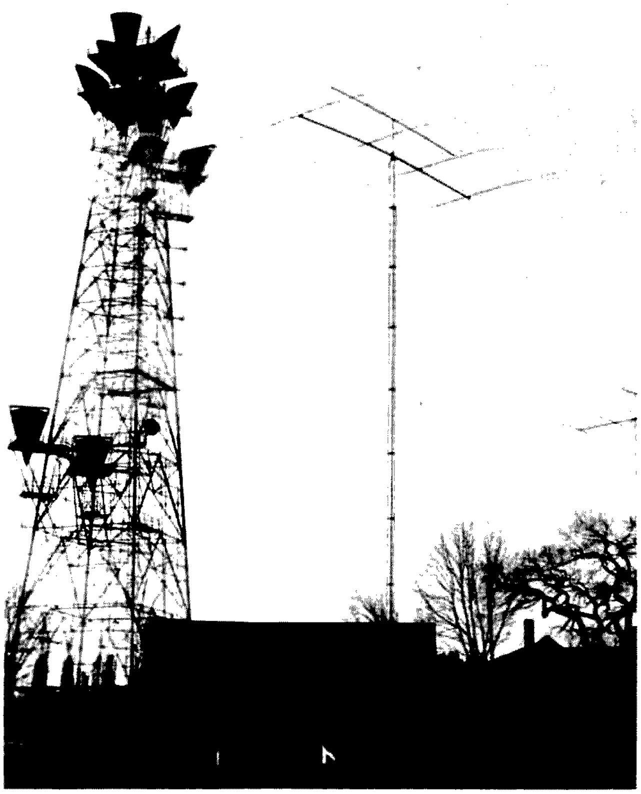
A Wayne King special feature in the Sunday *New York Times* gives us some insights into a few of the 100,000 complaints from the public received by the FCC in 1976. They represent some of the more fascinating items of RFI.

The strident tones of "jelly belly" startling a poor housewife as she opened her electronic oven . . . A character called "rubber ducky" shouting, "I'm comin' home, warm up the bean pot, honey" just as the minister was closing the coffin during funeral services . . . As another pastor said, "forgive us our trespasses," one "dragon lady" in less than dulcet tones came bleeding through the PA speakers with "That's a big 10-4, good buddy," — such ain't the way to perorate the Lord's prayer.

A raucous "hey, what say, good buddy" ruined the romantic moment for a Houston couple who were theretofore using to best advantage the soft music on their stereo. A Dallas police chief was equally upset when his electric organ started talking with a trucker's twang, even though the switch was off, and a southern chanteuse named Cheryl Russell found herself suddenly off-key and mentally anguished when her night club mike talked back to her. The New Mexico Cooperative Interference Committee investigated 11 meter signals which drove a local citizen to a psychiatrist — the fillings in his teeth were picking up more than one good buddy. CBers trying to get 9 pounds out of a 5 pound Tiger 23 have caused widespread havoc with electronic controls on fuel injection systems ranging from spitting VWs to sputtering Mercedes.

The FCC announces publication of a new 35 page booklet, "How To Resolve Radio-TV Interference Problems." It will be available from the GPO beginning in late June, for $1.50.

The K1VBL antenna farm last fall. Since the picture was taken, winter has done its dirty work, taking out the largest tower and forcing a rebuilding program this spring.



As is obvious from this shot, K1VBL let Ma Bell do his site research work for him. Most contestors are by now aware that it's paying off.

booklet includes interference information on TVs, BC radios, telephones, stereo systems, and other electronic devices.

Amateurs everywhere owe Fred Maia W5UTT a vote of thanks. Maia was a major contributor to the successful introduction of an RFI bill in this year's session of the Texas legislature. The RFI bill's introduction followed withdrawal of a measure that would have set criminal penalties on interference cases, strictly from the ham's or CBer's point of view. The new bill would force the installation of interference filters on TV sets at the dealer level, and place either a $100 fine or actual damages (whichever is greater) for interference caused by the lack of a filter. But the Texas amateurs and their supporters did not stop there. A section was added to the bill suspending normal legislative procedures to allow for early action and an immediate effective date for the new law upon passage!

The CB problem in Australia has become so bad that the state police can stop and search any vehicle suspected of carrying illegal 27 MHz equipment. All amateurs in Australia are advised by *Amateur Radio* magazine to carry their license or a photocopy of it with them. It is also required that they carry their license renewal certificate and a log book. Amateurs are further instructed to remove their mobile gear if they lend their car to spouses or friends, so the driver does not get booked for illegal possession of radio transmitting gear.

In "Briefs" in the May issue (page 40), an item appears which gives a false impression of the facts. It says, "A licensed amateur . . . was fined $100 . . . for inadvertent jamming of radio and TV shows . . . for which he could have been fined a maximum of $1600."

The facts are that damages of $25 each were awarded to four neighbors who had sued the user of a CB station for $400 damages each because, for about a year, despite repeated complaint, their radio and TV reception had been marred by a "strange voice" which intruded "at all hours of the day and evening."

In Canada, the Radio Regulations still forbid the use of CB for "transmissions of a frivolous nature" and "a communication used in itself as a diversionary or recreational activity," but in fact these prohibitions are not enforced. But another provision says, "no station . . . shall be operated so as to cause interference to any licensed radio station or a private receiving station." The sensible ham or CBer operates his gear with discretion, knowing that there is a fine and debatable line between his right to operate and the right of his neighbors to enjoy their listening and viewing.

The court case which ended in the judgment against the CBer was argued around the principle that the exercise of an act of ownership is subject to the exercise of the same right for neighboring owners. It was found that "the owner of such a device is responsible for its injudicious use if such use causes inconvenience to others. The theory of misuse of right must be applied here. The fact that one exercises a right does not mean that one may thoughtlessly, albeit without malice, interfere with others in the exercise of their rights."

Another interesting reference is to the possiblity of high pass filter protection on the TV sets. "It is false to claim that the owners of television sets should provide their sets with special filters, since the use of a television set is not regulated to the same extent as that of a CB device. Thus, the intangible damages incurred by the applicant must not be given any less weight because he did not provide his own television set with special filters." Thanks to VE7BS.

Amateur Radio News Service

We've heard about the ATV madness sweeping the country, but things are clearly getting out of handl Consider the proposal of some Baltimore (MD) ATVers, as published tongue-in-cheek in *The Milliwatt*, bulletin of the Baltimore Radio Amateur Television Society (BRATS). "Have you noticed that most commercial TV stations stop transmitting at night? Apparently they are not interested in using their spectrum 24 hours a day. Tell you what. When they go off, allow the hams to transmit ATV on those unused channels. Betcha dollars to donuts ATV would fill up those unused channels fast and attract more viewers than those moldy all-night movies. BRATS hereby announces its preliminary plan for channel 11 input, channel 2 output, ATV repeater for Baltimore." Thanks to K3SVC.

The Amateur Radio News Service was founded many years ago as a result of a need for the exchange of ideas among and between those radio amateurs concerned with club newsletters and public relations. In the newsletter field, ARNS attempts to cover all aspects of producing and mailing a club paper. To one entering the field it soon becomes evident that producing a club paper is somewhat of a unique process, primarily because standard practices of printing will not necessarily apply. The publisher seldom has equipment available and in many cases must operate without any equipment at all! Few club paper editors have had any experience in the field. It has been demonstrated that, through information available through the Amateur Radio News Service, a new paper editor can easily surmount many of the problems involved in producing a club paper.

The monthly publication, *The ARNS Bulletin*, contains in each issue helpful hints for producing the paper. Currently each issue contains an installment of the booklet "The Club Paper," bringing the publication up to date. These installments cover all aspects of producing a club paper, from the origin of the text to finally placing the papers in the mail. When completed, each member will receive a copy.

ARNS numbers among its members many professionals possessing expertise in almost any subject of producing a paper. Thus the newcomer has access to a recognized expert who can answer almost any question relative to producing a club paper. Because of the improvement in the club paper and since the editor has access to continuing information, most clubs pay the nominal cost of the editor's membership in the Amateur Radio News Service.

In the Public Relations field the Amateur Radio News Service endeavors to cover suggestions for operating in the public relations field, including types of items to be submitted to the media. Again, ARNS has among its members many who are professional public relations individuals, and each member has access to information available from them.

The Amateur Radio News Service has members in many foreign countries. It is a service for amateur radio editors and does not issue "news" items as such. However, each issue of *The ARNS Bulletin* contains quotes from other club papers which can be copied for use in any club paper. Thanks to W9MOL and WA3HEN.

For those interested in building the TV game circuit presented in the Oct., 1976, issue of *73* ("Hey, Look What My Daddy Built!"), and have either had trouble finding the AY-3-8500-1 chip or did not want to spring for the $35, we have good news! Poly Paks now has the chip listed on the front page of its newest (221) catalog, for $14.95. We thought this might make some of you happy. – WB1ASL.

Hams have come up with some ingenious uses for beeps. LIMARC, the Long Island Mobile Amateur Radio Club, uses a beep to tell you when you have paused long enough between transmissions for the machine to recycle. When you hear the beep, start talking.

Vancouver's VE7RPT machine beeps users when their regular power has ceased and emergency battery power is being used. Dave Williams VE7MQ says that the battery supply gives full emergency capabilities, but only for a finite duration. "If the beep tone is on," he writes in the *British Columbia FM Communication Association Bulletin*, "please be exceedingly brief, or better yet, limit your use to emergency traffic."

The Miami Valley FM Association *FM Scanner* reports that their 04/64 machine emits a double beep if an emergency is in progress. Monitoring stations are instructed to stand by and listen when the double beep is heard. Net control will then ask for check-ins if needed.

A wide area communications system, which has received FCC authorization, will consist of 6 or 7 strategically located repeater stations capable of retransmitting signals from weak stations, such as HTs, throughout the 30,000 square mile area around Kansas City. Each of the linked repeaters can be tone or carrier accessed as desired by the control operator. The repeaters may also be operated independently without interference between terminals. A complex set of commands will be given by the headquarters communications center (WØSHQ), which can monitor traffic on each repeater. A minicomputer, located at headquarters, controls the entire system.

The Association of Saint's Church Radio Amateurs, headquartered in Independence MO, says that the system is the only one outside of the western US to have such a large coverage area. Mountain-based repeaters in the west easily provide 200 mile coverage, while plains states have no such height advantage.

Congratulations are in order to the Cuyahoga ARS of Cleveland OH, after providing assistance to the local American Cancer Society during its annual fund drive. Mobile stations were provided by the local club, whose members delivered 365 cubic feet of literature and informational packets to zone captains for distribution throughout Cuyahoga County. Thirteen locals participated, along with a prospective amateur (a security guard at the Cancer Society headquarters building) who gave up a day off to join the hams! Thanks to WA8GEO.

CONTESTS

Official logs, check sheets, and summary sheets for the CAN-AM Championship Contest may be obtained from CANADX, Box 717, Station Q, Toronto, Ontario M4T 2N7, Canada. Include a large SASE for samples. Full rules for this contest will appear in the next issue!

QRP SUMMER CONTEST
Starts: 1500 GMT
Saturday, July 2
Ends: 1500 GMT
Sunday, July 3

The contest is organized by the DL Activity Group-CW. Work 15 hours maximum during the 24 hour contest period, with no more than two pause periods. Select up to 5 bands from 160 to 10 meters. General call is "CQ QRP TEST." A station is not handicapped if CO/VXO control *and* VFO control are used on the same band or the input power of a commercial rig is reduced to below 2.5 Watts. QRO stations — same rules, but work only QRP stations and sign ". . ./QRO"; scoring is the same.

EXCHANGE:

RST, QSO number, and input (1 to 9). Add "x" if transmitter is CO or VXO controlled. Example — 579 000/8x.

SCORING:

QSOs with all stations are valid unless running QRO; then only QSOs with QRP stations count. Contacts with your own country count 1 point, own continent = 2 points, DX = 3 points, and score 3 additional points for a QSO with another QRP station. Score additional handicaps as follows: 1 handicap point for each station using below 3.5 Watts input or crystal controlled transmitter. Maximum handicap is 4 for any QSO. Both stations multiply QSO points times the handicap points plus one (QSO pts x 5 max) to find total QSO points for that contact. Multipliers are as follows: own continent = 1, DX = 2 points per band and country according to latest DXCC list, but call areas in JA, PY, VE, VK, W, and ZS count extra. Final score is total QSO points (including handicap pts) times the total multiplier.

ENTRIES:

Send entry including a "mini-log" to Hartmut Weber DJ7ST, D-3201 Holle, Kleine Ohe 5, Fed. Rep. of Germany. Logs should be postmarked no later than Feb. 15.

ARRL STRAIGHT KEY NIGHT

Complete rules in June issue of *QST!*

If similar to last year, starts 0100 GMT July 3rd and ends 0700 GMT July 4th. Send "SKN" instead of "RST" during QSOs to identify contest stations. Try 60 to 80 kHz up from bottom edge of the band. After contest period, send a list of calls of the stations contacted during the contest period plus your vote for the best fist heard. All entries should be addressed to ARRL, 225 Main St., Newington CT 06111.

APOLLO II 8th ANNIVERSARY CONTEST
July 16 to 17
6 pm to 9 pm local time

Use all VHF/UHF bands, all modes — except repeaters!

Power classes as follows: Class I — 100 to 300 Watts input; Class II — 25 to 100; Class III — 5 to 25; Class IV — 1 to 5. Special XYL class — any power permitted. Club class — aggregated scores.

SCORING:

Each completed contact counts 2 points. Same station may be reworked on different mode and/or band for additional 2 point scores. Each different zip code worked will count as 1 multiplier; like zip codes worked will not be counted as a multiplier.

AWARDS/ENTRIES:

Trophy plaque to highest score in each power class and XYL and Club classes. Space Net certificates to second and third places in all classes. All logs to be postmarked no later than Aug. 10, 1977, to: VHF Space Center, Box 15, Sumterville FL 33585.

TEN-TEN INTERNATIONAL NET SUMMER QSO PARTY
Starts: 0000 GMT July 16
Ends: 2400 GMT July 17

The contest is open to all amateurs, but only members are eligible for awards. All contacts must be made on 10 meters, but any mode may be used.

EXCHANGE:

Name, QTH, and 10-10 number.

SCORING:

Score 1 point per contact and add 1 point if with a 10-10 member (max. 2 pts per QSO). Give name of your chapter for chapter credit.

AWARDS:

1st and 2nd place certificates for each US Dist, KH6, KL7, VE districts, Central America and Caribbean, South America, Europe, Africa and South Atlantic, Asia and North Pacific, Australia-New Zealand and South Pacific.

ENTRIES:

Members only send logs to Grace Dunlap K5MRU/Ø, Box 13, Rand CO 80473 no later than Aug. 31, 1977. Results will be published in the Fall Bulletin. Special certificates for all CW scores and if 10 or more logs are received from Novice members.

CW COUNTY HUNTERS CONTEST
Starts: 0000 GMT July 23
Ends: 0600 GMT July 25

The CW County Hunters Net invites all amateurs to participate in the 1977 CW Contest with all mobile and

CALENDAR

July 2-3	QRP — Summer — Contest
July 4	ARRL Straight Key Night
July 9-10	IARU Radiosport Championship
July 16-17	Apollo II 8th Anniversary Contest
July 16-17	10-10 Net Summer QSO Party
July 23-25	CW County Hunters Contest
Aug 20-21	New Jersey QSO Party
Aug 20-21	Worldwide SARTG RTTY Contest
Aug 20-22	CAN-AM Championship Contest
Aug 27-28	All Asian Phone Contest
Sept 10-11	Washington State QSO Party
Sept 10-11	ARRL VHF QSO Party
Sept 24-25	Delta QSO Party
Oct 1	Open CD Party — CW

**Multi-operator station.

Ten-Ten Net Chapters:

Southern New England	7614/14,426
Gateway (Missouri)	5683/11,010
Cincinnati Area Ten Tuners	4920/9,374
Colorado	3316/6,251
Bay Area (Cal.)	3242/6,137

portable operation in less active counties welcomed and encouraged. General call "CQ CH." Stations may be worked once per band and again if the station has changed counties. Portable/mobile stations changing counties during the contest may repeat contacts for QSO points. Stations on county lines give and receive only one number per QSO but count each county for a multiplier.

EXCHANGE:

QSO number, category (P = portable, M = mobile), RST, state-province-country, and county (for US stations).

FREQUENCIES:

3575, 7055, 14070, 21070, 28070.

SCORING:

QSOs with fixed station count 1 point, portable/mobile stations = 3 pts; multiply QSO points times number of US counties worked. Mobiles/portables calculate their score on the basis of total contacts within a state.

AWARDS:

Certificates awarded in three categories: F — Highest fixed or fixed portable in each state, province, and country with 1,000 or more points; P — Highest station operating portable (not normal point of operation) with 1,000 or more points; M — Highest mobile in each state operating from 3 or more counties with a minimum of 10 QSOs per county.

Trophies to highest single operator station in categories P and M. Additional awards where deemed appropriate.

ENTRIES:

Logs must show category, date/time in GMT, station worked, exchanges, band, QSO pts, location, and claimed score. All entries with 100 or more QSOs *must include a check sheet* of counties worked or be disqualified from receiving awards. Enclose large SASE if results desired. Logs must be postmarked by Sept. 1 and sent to: CW County Hunters Net, c/o Jeffrey P. Bechner W9MSE, 673 Bruce St., Fond du Lac WI 54935.

TENTH ANNIVERSARY JERUSALEM AWARD

The Jerusalem Award Committee announces the creation of a new certificate to commemorate the tenth anniversary of the unification of Jerusalem. The certificate will be made available to both amateurs and SWLs. To qualify, contact 8 amateur stations in Israel, with at least 3 of them located in Jerusalem, the capital. All contacts must be made in the year 1977! Have log entries certified by another radio amateur and send log extracts along with 10 IRCs to: Jerusalem Award, PO Box 4079, Jerusalem 91 040, Israel.

Also of note: The requirements for the regular Jerusalem award have been changed to require contacts with 8 stations in Israel, with 3 in Jerusalem. The address is the same as shown above.

IARU RADIOSPORT CHAMPIONSHIP

Complete rules in the June '77 issue of *QST!*

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz.
OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz.
Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

Corrections

Thank you very much for printing my crystal checker circuit on page 164 of the April, 1977, issue of your great magazine. There is only one small error in the schematic. Due to a misprint (I hope), the transistor part number reads 50011. It should be S0011. I think that whoever builds the circuit will understand the error.

John Mairs WD4CEA
Springfield VA

I have had considerable mail response on my article that was in the May, 1977, issue of *73*, "All-Electronic SELCAL." I have one thing to say: "These hams who are supposed to be dummies can really pick out the errors." It has been brought to my attention that all the 5 volt power leads to the 7473 flip-flops have been reversed. That would be IC1, 2, 3, 4 and 5. Also, Q1 and Q2 have been labeled incorrectly — they should be reversed. These are all my errors; I should have caught them but did not. You did make one error, and that is that resistor R3, which goes to the collector of the 2N706 and got its base driven from input 15, should also be connected to the vertical line that goes past it on the right-hand side (to the manual reset button).

A. Sperduti WB2MPZ
Hamburg NY

My apologies to those people who have had problems with the "NASA-type Beeper" in the January 1977 issue. The value of C5 which determines the tone of the beep should be .01 uF instead of the .001 called for. The .001 produces a beep of around 10 kHz — high enough that most people thought that the circuit was not working at all. With this change, a 1 kHz tone is produced.

Also, in Fig. 2, the ground pin of U1 is labeled GND but not connected to ground, which it, of course, should be. Fig. 1 is correct as shown.

Bob Shattuck WB3GCP
Gillett PA

This note is to advise you that there is an error in the text that accompanies the circuit I sent you for the Circuits^2 section of *73* which appeared in the April, 1977 issue, page 164. The schematic is correct as printed, but the fuse rating should be less than the current rating of the SCR. This is so that the fuse will blow before the rating of the SCR is exceeded. If the SCR's rating was exceeded, the SCR would be destroyed, of course.

I thought that you would like to be advised of this error. Thank you.

Paul Hurm WB8CLF
Seven Mile OH

I was very pleased to see my circuit published in the April issue of *73*. However, I must point out a mistake. The 470k resistor on the output of the op amp in series with the bipolar LED is incorrect. The value which I originally used was 470 Ohms.

LETTERS

NOT SURE

Last year I saw an article in your magazine (I think it was your magazine, but I'm not sure) which interested me very much, but I have forgotten what it was. I wrote the name of the article in my notebook after I had read it, but I have lost the notebook.

I have also lost the magazine which the article was in. Will you please send me another copy of the magazine, if it was your magazine?

Wayne Schuler EP2US
Tehran Iran

P.S. Keep up the good work . . . whatever it is you do.

Try the Guide to Periodical Literature, *Wayne. Perhaps you'll find a reference to your missing article! — Ed.*

HARMONY

I harmonize with your February 1977 *73* editorial. But I cannot sing, so I yodel. I am heart hurt over the ARRL *QST* format, monstrosity advertisements, miniscule matter of direct interest to me (licensed since 1935 — W6MMZ and KL7DG only calls — past 12 years with FCC Monitoring, Anchorage). I am an ARRL member and once served as Alaska SCM. Recently I subscribed to *Sky and Telescope* in place of renewing *QST*.

Enclosed is a copy of my QRPp 27 meter band proposal which *Worldradio* carried for me but *QST* would not print. Can you give this idea some emphasis? FCC has not yet responded to my proposal of January 7, 1977, but I am braced for a long wait in this quarter.

John P. Trent KL7DG
Anchorage AK

I am proposing shared use of 11.300 to 11.325 MHz by very low power A-1 emission only for the Amateur Radio Service with the Aeronautical Mobile Service on a shared non-interference basis, worldwide.

Power limit for the Amateur Radio Service would be 5 Watts input. This would provide better than 15 dB protection in all areas of the world.

This proposal has been prepared in an original and 19 copies in response to Docket No. 20271 dated 6 December 1976 which treats WARC-79 allocations with the binding effect of treaty to signatory countries until the year 2000.

In this Docket No. 20271, the Amateur Service is marked for a reduction of its 15 meter allocation by 250 kHz shaved off the top of this band and reallocated to the Maritime Mobile Service. This is a significant loss of frequencies not entirely offset by proposing the addition of 50 kHz to the bottom of the 20 and 40 meter bands and the establishment of 160 to 190 kHz low frequency band for amateurs.

For more than a decade, the 11.300 to 11.325 MHz section has been observed by me. I have noted quite limited use of these frequencies by the Aeronautical Mobile (R) Service. On a nightly basis, unlicensed Chinese fishing boats with spurious A-1 emission use the 11.300 to 11.325 MHz frequencies for navigation and commercial fish catch information.

Insertion of a vaccine type active amateur on very low power will serve to develop thousands of intruder watchers to assure the band purity for primary use by Aeronautical Mobile Service.

John Trent KL7DG

HIGH STANDARDS

First of all, I would like to congratulate you for the fine efforts that you have put into amateur radio and also *73 Magazine*. I do not always agree with you, nor do I enjoy computer articles, but it is impossible to please all of us.

Being from Canada, perhaps it is wrong for me to criticize the FCC license standards, but I feel it is wrong to keep lowering the high standards of amateur radio to accommodate a small group of lazy individuals who cannot be bothered to put forth a reasonable amount of time and effort to become amateurs. I for one am not against a Novice class license, as it provides valuable on-the-air experience, but I do feel that the present code and theory tests are too relaxed (with the recent power increases). If the present trend continues, all we will get out of this is a glorified Citizens Band, which I am sure no serious amateur ever wants to see. The present rules which allow a person to go from Novice to Extra class in almost no time at all are wrong, as a lot of extra studying does not make up for time-tested experience.

The majority of amateurs are far too eager to get onto voice. Anyone can learn how to talk into a mike. It's done every day by common people, but it takes a good amateur to become proficient in CW. Tune across the CW portion and see how much really good CW you can find. Sure, there's a lot of speed, improper spacing or none at all, and Es and Rs sent like Fs. CW is nothing to be ashamed of — it was the beginning of amateur radio.

The benefit of properly conducted code and theory classes, along with good study material, cannot be overemphasized. The *73* code tapes and study guides are excellent, whether you are just starting out or are planning to upgrade your license.

I would like to explain what a Canadian amateur has to do to get his first license. First of all, there are only two classes: Amateur and Advanced. The first item is the following seven diagrams: (1) an AM and CW amateur receiver; (2) an AM and CW amateur transmitter; (3) a full wave tube-type or solid state power supply and necessary filters; (4) an overmodulation indicator; (5) a series or parallel wave trap; (6) a frequency measuring device (100 kHz crystal calibrator); and (7) a key click filter. A pass mark of 50% on diagrams is required. The theory exam consists of 50 questions, 25 on theory and 25 on rules and regulations. There are 4 different exams for those who write in groups, so the person beside you will get a different exam. The pass mark on theory exam is 70%. Many of the questions on our first exam appear on your Advanced or Extra class exam. The code exam is 10 wpm on both send and receive, and lasts for three minutes. The pass mark is 100%.

Our first license allows us to go on any portion of any of the HF amateur bands, but with CW privileges only. We are allowed voice on 6m and above. After six months we may apply for a 10m voice endorsement, but we must send in our logbook so that the DOC can be sure we have enough hours logged before it is approved.

Before we are allowed to write the Advanced exam, we must have held the first license for at least one year. The Advanced consists of a more stringent theory exam and a 15 wpm code exam (both send and receive, again for three minutes).

Power limits are 1000 Watts input for both classes, but on 160 and 432 there is considerably less allowed.

Garry Miller VE6AKW
Redcliff, Alberta
Canada

THE AVERAGE

I have been reading your magazine for about a year now, and overall I am very pleased with it. The articles are broad in scope and cater to many varied interests. However, from my own point of view, perhaps I can offer some constructive criticism.

I consider myself to be typical of the "average" ham. My station is fairly modest, and I operate SSB and CW, although I do have a desire to branch out into other areas. The trouble is, I really haven't seen the type of introductory articles in *73* that are both informative and easy to read. The articles I have seen are either at one extreme or the other: so basic that they offer virtually no concrete information, or so technical as to be above my head. I guess I'm referring specifically to RTTY and SSTV. Many excellent articles regarding other areas have appeared. How about some intro articles or even a series for guys like me?

You get input to your magazine from people like me who take the time to write. But what about all the other "silent" pens out there? Have you ever considered printing a detachable survey in an issue of *73*? I think there are a lot of guys out there who would like to see some really practical articles, e.g., how to build a steel tower using readily available materials, beam construction, etc.

I've been tempted to write a couple myself, but don't really know how to go about getting them published. So much for my criticisms. Regarding yours (of the ARRL), I think that while at times it is outspoken and unfounded, it *is* necessary. The ARRL *could* use some changes, and someone has to speak out. As an ARRL member, I can't recall them asking me if it was OK to build that new wing on their building. Perhaps the funds could have been put to better use elsewhere.

Maybe you don't agree with some of my ideas, but I think it is important that you get as much feedback about *73* and amateur radio as possible. And seriously, have you ever considered starting an organization analogous to the ARRL?

Gregg Corsello WB3CDK
Pittsburgh PA

Check our new "RTTY LOOP" column for beginning info, Gregg. — Ed.

RISQUÉ

A great deal has been published in *73* and several other amateur magazines concerning improper operation, questionable conduct, and risqué comments on the ham bands. However, a major problem has been ignored, or forgotten.

I have been a ham for almost a decade, and have heard just about everything on the bands, including a favorite (?) station in Newington CT, which choses to jump right on the West Virginia phone net, the night following the disaster in that area, only to announce, over the net control, that the frequency, 3990 kHz, was an emergency frequency. This is almost minor, though, compared with the problem of prospective hams being driven away by the "ham in a rut." Such operators consist of people like one I spoke with on the air the other night, who kept referring to "we" ("we are studying for our doctorate . . . we have been licensed for fifteen years," and so on). I honestly believed that the person with him (his wife) was also a ham, and was also studying for a doctorate. He sounded upset when I congratulated him and his wife on their achievement, as he must have thought everyone knew that "we" means "I".

Boy, am I weird!

Other all-time greats include "XYL" (how would a male operator like to be called XYM?), and the assumption that all hams are OMs. My wife Nancy recently received her Novice ticket, and has received subscription offers from *QST* and *Ham Radio* which opened with "Dear OM." Her name is not usually used to name anything but women or girls, right? And then they have the nerve to expect her to subscribe? Those letters were promptly filed, not by a person who objects to being called a person's wife, but by a lady who objects to being called "OM."

Then there is the usual "Hi-hi" which is often used for a laugh on phone. If a person responded to a joke while talking with you in person by saying "Hi-hi" you may be tempted to call for the men in the white uniforms. It is also rare that you hear a contact (pronounced kyoo-soh) which does not contain at least ten "Rah-gers," or *someone* saying "ahhhhhhhhhhhh," while trying to think of something else to say.

Nobody should be expected to use perfect grammar at all times, but if you record your half of your next few contacts on tape, you may find that you may be boring other people into oblivion! I tried this method, and cured myself of saying "uhh" (too many "uhhs" can drive a prospective ham away forever). I have heard from many a Novice who could not understand why the clichés used on the air have to be used at all. Do they?

Jerry E. Falletta WA2DWN
Elmira NY

No! You said it, Jerry. Unfortunately, many of the old CW timesavers have been applied to phone where they lose all their value. Let's speak English. — Ed.

KNEE JERK

How about a reasonable approach to the CB problem? At least they could try it while holding off a little while on the linear ban. I hope you will push this or some reasonable alternative.

Roger H. Taylor K9ALD
Champaign IL

Federal Communications Commission
Washington DC

Gentlemen:

I seldom write to any government agency, but your proposal for a ban on linear amplifiers capable of operating at 27 MHz, and for type acceptance of amateur equipment, has got to be one of the poorest thought-out regulations ever conceived. Let me point out a few of the negative aspects and then go on to make a much more workable suggestion.

First of all, you are punishing, both economically and otherwise, a large group of innocent people, namely amateur radio operators, for the law-breaking activities of an entirely different group of people. You would also be perpetrating a serious negative effect on the various purposes of amateur radio, particularly Sec. 97.1b, and many of your previously restrictive regulations have made it difficult enough for amateurs to live up to that section. Despite this, virtually every major advance in the communications art has come from amateur radio, as you well know. Don't hamper us even more.

Your proposal is a typical "knee jerk" bureaucratic reaction to public and congressional pressure to do something even if it is wrong and shows a real lack of understanding of human psychology and the facts of life, as many of your past decisions have also shown (such as the $20 CB fee that started the mass illegal operations on CB). Your proposal will do nothing to solve the problem that now exists or affect it for the next ten years at least. There are millions of linears now in existence and in the hands of CB operators. You will simply put many more people to work in their basements turning out bootleg amplifiers. Your proposal will have the same success as prohibition — for the same reason. Many CB operators use high power amateur equipment without linears anyway, and if you think that type acceptance of equipment will prevent modification, regardless of any laws passed, you have your head in the sand and no real appreciation of the technical competence and ingenuity of the American people.

Your limited resources have already forced the abandonment of some type acceptance for CB. Why on earth do you want to add even more of a load when you can't handle what you have got already? There is a much simpler way. Make detection and punishment for illegal operations much more probable, in the following manner. Since it is in the interest of the broadcasting industry to eliminate unlawful interference, ask their cooperation in making a few "public service" announcements, briefly stating why it is in the public interest to maintain legal, proper, and interference-free use of the public airways for everyone's benefit. Give a toll-free number for people to call to report interference, and ask them to give as much information as possible. A few of these announcements, which you could start next week, would drastically reduce the problems immediately. Just the knowledge that the FCC was really serious about stopping it, and the availability of a number that would be used to pinpoint illegal operation, would have real effectiveness. Your publicized raids have had a real effect already. Use psychology to help you, instead of trying to row upstream against it. If I knew that every time I fired up an illegal transmitter several people within a block of me were going to tell the FCC where I was (within a few hundred feet), do you seriously think I would do so?

This is a real opportunity for a government bureau to show both Congress and the American people that they can act quickly and effectively against a real problem by enlisting the aid and cooperation of the people, rather than taking many months to impose ever more restrictive and unworkable regulations. The cost to both the government and the public would be minimal. Certainly the broadcast industry would be willing to carry a public service announcement by the FCC which regulates them and is definitely in their own interest at no cost to the government. Abraham Lincoln said that the government should do nothing for the people that they can do for themselves. It is about time the government realized the wisdom and value of that statement. The political benefits from this approach and the publicity from a visible cooperative effort between a government agency and the public can't help but benefit both. If you really want the interference problem solved in the foreseeable future, this is a swift and sure way to do it while punishing *only* those who are guilty. The publicity and fear of detection alone would stop over 90% of it and make the rest of your cleanup job infinitely easier.

Somewhat along the same lines, the opening of ten meters to the Technician license would strongly encourage the transfer of the millions of CB operators who are now becoming interested in radio communication to join the ranks of the amateurs. The jump from nothing to the General class license is just too big for most of them. There is no logical reason to restrict ten meters, now relatively empty, to General class licensees, with millions of people wanting to use it if they had a fighting chance of earning a license to do so. Amateur radio has shown a tremendous ability to be self-policing and there is something about earning that license that makes people want to use their privileges properly. You brought in incentive licensing, which has stymied amateur growth for 10 years; now use that concept in a positive way by making it easier and more attractive to those who are interested in long distance amateur operation to get started in the type of operation they desire on the (near) frequencies they are used to using. You started this whole CB mess and have compounded the problems with some very unwise and short-sighted decisions. *Don't punish the wrong people with even more of the same.*

Roger H. Taylor W9ALD
Champaign IL

UPSALA QUAD

When building a boomless, 3 band, single feeder quad, I faced the following problems:

1. Element lengths had to be adjustable, which meant adjustable fastening points on the spreaders (no stubs were used).
2. Because of the complex geometry caused by the common feedpoint, the corner points of the elements also had to be adjustable in order to divide stress between elements and assure a perfect quad shape.

As most magazine quad designs were found to use very primitive

methods for element fastening, I found I had to work out my own solution. The following points should be noted:

1. A hose clamp allows sliding the element along the spreader.
2. The element is made from soft plastic-covered stranded wire that slides, when necessary, relative to the piece of copperless glass/epoxy board.
3. A small stainless steel shackle (can be obtained from distributors of yachting equipment) allows complete removal of the element.

EXPEDIENCE

Two articles in March *73* concerning MARS have caught my eye.

In the first, by Marc I. Leavey WA3AJR-ACM3AJR, it appears that Dr. Leavey is either not very familiar with Air Force MARS callsigns, or that Air Force MARS has made an error in mine. And I'm relatively certain that the latter is not the case.

Having been the Air Force State MARS Director for Kansas at the time the callsign changes were made, I became fairly familiar with them. AF MARS callsigns formerly were:

Prefix	Air Force
Wn	AFn
Kn	AFAn
WAn	AFBn
WBn	AFCn
WNn (Novice)	AFNn

When changed to the three letter prefix, the callsigns became:

Wn	AFWn
Kn	AFAn
WAn	AFBn
WBn	AFCn
WBn (Novice)	AFCn (Novice)

The most expedient route, that involving the least additional paperwork, was to change the Wn call to AFWn. During a time when paper costs have been rapidly increasing, Air Force MARS should be commended for its insight.

Novice calls remained unchanged until the FCC began issuing them WBn calls, at which time they also became AFCn.

In the second article, where it is stated, "There is a place where Tech-

nician class licensees can operate SSB on HF, and where Novices can operate voice on 2 meter FM," just what is there to prevent a Novice from now operating SSB on HF? I think that he may in Air Force MARS.

Further in this article, extra privileges, distinctive callsigns, and access to surplus equipment are alluded to. But if a potential member signs up in MARS solely to obtain excess property, he just may find himself storing excess government junk along with that that he can use. For in the past, some items have come out in that condition. Steps have been taken to rectify this situation, so it should be better in the future.

One final thought. The address given for further information is that of Army MARS only. Perhaps you should dig out the addresses for the other MARS services also, and present them. The AF MARS address is Command MARS Director, Hq AFCS/DOYR, Richards-Gebaur AFB MO 64030.

KEYER UPDATE

You may be interested in the enclosed comments on "Build the World's Simplest Keyer." Re your May article, "Stop Timeouts!", I hope that you can join with us in trying to kill the idea of "10 minute timers." What the timer says is, "You just broke a regulation!" Better to set them at 8 minutes or 9 minutes. Of course, the timer with readout partially fixes this.

Another problem is short transmissions, since the other guy might take over and still be sending when your ID is due. Therefore, it is always best to give one sign when turning over. Also, note that phonetics generally are necessary with phone, to prevent misunderstanding the call.

I was interested in your article in *73 Magazine* (May). It may be that it can be simplified some more, and improved.

I note the relay, which is a "no-no" in CW because of the mushy key clicks when one gets contact bounce in them. Note *73* for September, 1965, ("Der Kleiner Keyer," by E. L. Klein). He simply used a PNP transistor, handling 150 volts, and keyed the transmitter grid circuit directly, with no relay. Cheaper than the relay, too!

Next, there are four pots. That makes it both complicated and expensive. For one thing, one might get rid of the "weight control," as being undesirable. Second, it may be possible to use only one pot to control both the dot and dash sides, possibly by using the right capacitors for the dots and dashes and the one pot. It appears that there are some alternatives to the second (dash) 555. One is to make it simply fill in the space between dots, as "Der Kleiner Keyer" does with a flip-flop. It seems that it can be arranged. The other alternative is to dispense with the 555 and use a flip-flop to do the filling in, with no adjustments at all.

As to VR1, it may not be required. I don't use any in the Kleiner keyer. If one uses a bridge rectifier and a 6.3 volt transformer, if available, one comes up with a pretty fair voltage to operate the keyer if no VR is used. The possible shortcoming might be not having completion of a suitable space after each dot or dash. Where there is a free running MV, this may be almost automatic, of course, within a letter. So putting in something for space between letters may be a complication.

You might look at the combination ICs which include a multivibrator. They may handle most of the keyer in one piece without a lot of external parts, if you find the right thing. It might be best to look at the CMOS availability anyhow, in order to cut the power drain down so far that you can go to a battery and throw away the on/off switch, remembering that the 2N398B keyer transistor runs off the exciter grid current, and does not get any power from the keyer.

E. H. Conklin K6KA

MORE TECH DEBATE

I am writing regarding the letter in your Feb. '77 issue, "Tech Relax," from L. N. Thompson. I apparently missed your editorial on the subject, but agree strongly with Mr. Thompson.

I feel that Technicians should be allowed use of SSB phone privileges on some parts of the 10-160 meter HF bands. If not, then I believe that the current 13 wpm code standard for General class should be reduced to 10 wpm. I have written the ARRL and the Chief of the Personal Radio Division concerning the above.

I urge everyone who feels that the present 13 wpm code speed is too high for the General license and that Technicians should be granted some SSB phone privileges on the HF bands to write the FCC and their congressmen and senators. I personally am sick and tired of hearing the older hams make statements like, "If they want higher privileges, let them work for them like we did." No wonder there is such a high dropout rate of Novices and Techs. No wonder so many Techs get on 2m FM and stay there. I admit that 2 meters is a busy band, but I have yet to hear it sounding like the CB frequencies — so that is no excuse for denying HF SSB phone privileges to Technicians!

Most of us have spent a lot of money on our hobby and equipment only to be denied use of it because of snobbish and archaic standards established many years ago.

Although my subscription just started this year, I am renewing for another year. Keep up the good work and the excellent articles.

John A. Magness III WD4BVU
Murray KY

"Kitty" is WBØDQW's latest ham convert.

KITTY

Enclosed are some photos which may be of interest to you. As you can see, my recruiting efforts for amateur radio do not stop at human beings. Kitty didn't think much of the key, though.

Thanks for your fine magazine. Keep up the good work!

Neil Preston WBØDQW
Kansas City MO

HEX TO BINARY

Small point, but I'm curious why Joe Larson's letter (page 116, Feb. *73*) misquotes the figures he is using for illustration. Joffe's article uses the expression "3A7B"/Decimal 14971 (page 94, Holiday issue). Larson quotes this as "39BD"/Decimal 14781. Larson's points are well made, especially the conversion from hex to binary.

Bill Straley
Campbellsville KY

NO PR-40?

WA4KDC's operating system appearing in the March, 1977, I/O section of *73 Magazine* is fantastic! The only problem is that although everyone should have it, not everyone does have a PR-40 printer.

I thought you would be interested to know how I slightly modified the program to allow printout on my Teletype. The modification consists of modifying addresses beginning at 01EE with the following:

01EE BD E1D1
01F1 33
01F2 FE A014
01F5 39

Hufco, Inc.
Provo UT

EARTHQUAKE

On the evening of Saturday the 5th of March, I assisted people searching for relatives in Romania during the recent earthquake there.

I wish to remark here that besides all kinds of complaints about the traffic on the upper part of the European 80 meter band, the traffic was handled in a very efficient way, with little amateur QRM. Everyone requested to stand by or QSY did so in the best possible way.

The network established traffic between Western European and Israeli stations, via Daniel YO8AHL in Iassy (located about 500 km north of Bucharest), to Bucharest, the capital city, where other amateurs and what was left of the telephone system did the rest. Also, I would like to thank the Yugoslavian stations that gave me assistance in finding the Romanian emergency network's frequency.

Jac Lirola F6CVU
Truchtersheim
France

THE HFERS

One of the acknowledged factors in the increasing proliferation of the so-called "Hfers" is the easy availability, without challenge, of amateur equipment to non-amateur persons. This accessibility has led to serious talk, even a Notice of Proposed Rule Making, of banning the sale of linear amplifiers capable of operation between 25 and 35 MHz.

It seems, therefore, that because of a few unscrupulous dealers eager to make a quick buck, many amateurs may either be unable to buy a 10 meter linear, or will have to pay a higher price to offset type acceptance costs. At least one dealer in Chicago and one in Milwaukee have no interest in whether a potential customer is or is not a licensed amateur. Spectronics in Chicago, on the other hand, states quite clearly, in ads and in their store, "No call, no sale."

It makes me proud that Art Householder and company have chosen to eschew a few extra sales to help preserve the integrity of the hobby. And, he enjoys my business as a result. My challenge to you is to do your part in preserving the integrity of the hobby by tightening up your already comprehensive advertising policy to refuse space to those dealers who do not restrict sales of amateur transmitting equipment to licensed

amateurs.

Word of mouth is a pretty effective policing system (witness Trigger), and any advertiser not living up to the rules would be quickly exposed. Remember — today the linears, tomorrow the transceivers.

Rod Peterson WB9UQX
Carol Stream IL

THE NEW BREED

I am writing this letter to you and to those who would submit construction articles to you in the future. I would like to think that I am speaking for several thousand newcomers to amateur radio as well. Most of us cannot read schematics. Most of us do not have "junk boxes" stuffed with scrap suitable for use in construction projects. And many of us do not have a fully equipped machine shop at our disposal. The nearest electronic parts supplier is usually a Radio Shack store. And, we do not appreciate being referred to as the new breed of ham who buys his rig and plugs it in, but with such poorly illustrated construction articles, you don't leave us much choice. If a picture is worth a thousand words, then many of the projects could be shortened with the insertion of pictures showing the parts layout.

So please help us gain the expertise you have by submitting and publishing complete photos of your projects, parts lists, and suppliers of parts. Please be accurate in your details.

Think back to when you were a newcomer to amateur radio and help us get off to the right start.

John A. Magness III WD4BVU
Murray KY

P.S. I would like to buy any back issues you may still have. Please send list and price.

Right on, John. Old-timers, take note! Check any recent issue of 73 for a list of back issues. — Ed.

THE FAMILY

I just finished reading "HAM vs CB" in the May W2NSD/1 editorial. I am one of the many hams who came here through the CB *family*, as you called it. I received my membership papers to the family in February, 1976, and by March was so discouraged with the situation that I immediately contacted the Bluegrass Amateur Radio Club to get information on a Novice class they were holding. By July I held WA4RUW with Novice privileges. It's nearly a year later, and I am still a Novice, but I don't want to get back on 11 meters just to operate phone. You feel that CB is in a different family and hams have no business messing in those affairs — I agree partially. But when I go down to 10 meters to look for a rare 10m QSO, all I find is "Harry Top" talking to "Junk Yard Dog," on 28.169 MHz! Do you still feel like we shouldn't mess in those affairs? Being an ex-CBer, I used the old tactic of more power and zero beat, and started calling CQ on frequency. The reaction was surprising — more power and four letter words! The two handles used are fictitious, but the incidents are true. With 11 and 10 meters so close, CB is a close cousin to ham, and I feel there are some family affairs we need to concern ourselves with.

Bob Cornett WA4RUW
Lexington KY

11M TO 10M

I read with great pleasure the article by Bob Wilder ("CB to 10 . . . A Legal Alternative," May, 1977), and strongly endorse his plea to encourage the use of CB transceivers on ten meters. I would, however, suggest one major consideration which I think should be worthy of serious thought, at least as a viable alternative: the use of an external transverter, rather than internal modification. A number of transverter articles for VHF bands have been published. The advantages of this approach are numerous: no modifications to the CB set to destroy its resalability; no tampering with the transmitter section rendering the set illegal for further CB use; simple external switching would provide alternate CB or ten meter use. The band plan suggested by Bob Wilder would still maintain its integrity, as the heterodyning transverter would still provide the ten kHz incremental tuning which he suggests. A standardized (hint to prospective manufacturers) transverter would be applicable to any CB transceiver, and complicated internal synthesizer formulas would no longer be a consideration. See you on ten!

Bob Grove WA4PYQ
Davie FL

OSCAR ORBITS

A common assumption regarding the OSCAR satellites is that the period (time of one orbit) and increment (number of degrees west the satellite appears to move) both remain constant. Several programs appearing in *73 Magazine* recently use this principle to calculate the position of the satellites by inputting a starting position (equatorial crossing point) and time, and incrementing the constant interval for the succeeding orbits.

I wrote a simple BASIC program to do exactly this, and everything looked fine until I ran out the calculations to the end of the year (4500 or so orbits). There was a small but appreciable error which I couldn't account for when I compared my results with the book of orbital times published by Skip Reymann W6PAJ. This book was compiled from data computed by Tom Clark WA3LND, so I wrote him. To quote his note to me, "Since the period and orbital longitude increment are *not* constant, . . . I provided W6PAJ with weekly period/longitude increment data, but he chose to print one value for the year."

So, programmers beware — your results will be close, and will be usable, but they won't be entirely correct.

Aiea HI

CHEAPER THAN EVER

I have subscribed to *73* for about four months now, and I have come to conclude that it is the best amateur radio magazine on the market. When I pick up a magazine, I expect to see articles that I can get some good reading out of and that I can learn a thing or two from.

I really enjoy your I/O section and I hope it will stay the way it is even though the new magazine *Kilobaud* has come out. I really wish I could subscribe to *KB* but my budget doesn't allow it.

I am really interested in WA0TSY's idea about converting CBs to 10 meters, since I used to be an avid CBer and have some equipment around that I am willing to make the switch with. I hope others will see this idea so that it may catch on, as CBs are cheaper than ever, and this would be an economical way to get on 10 meters. Maybe you could include some articles on this idea and conversion details in your upcoming issues of *73*.

John H. Peeler WA4UYI
Denver TN

They have started coming, John. See last month's issue. — Ed.

PC REFORM

A hearty "well done" to your staff for the articles on printed circuitry! I just had a chance to finish reading both of them and I must say I wish I could have read these articles three years ago when I started working with printed circuitry. I had to develop my own methods and spend an indecent amount of money to get good results. Your readers may not realize how difficult it normally is to get good information on PC fabrication. The majority of the trade manuals are as vague on such items as exposure times and others as a politician is on political reform. And many magazine articles leave out critical information, to boot! Thanks again for putting a light at the end of the tunnel!

I can't resist putting my two cents worth in. If you are working with PC fabrication for the first time, follow each step carefully and use fresh materials. Then, after you are successful, you can take shortcuts. If you start with the shortcuts, you will probably end up with a bad board and no idea of what went wrong. And that means confusion!

If you have a problem with the resist washing off the board during the

see page 205

etching process, this means either that the copper was too dirty or the copper was too smooth. You can often solve this problem on the next try by drying the exposed and developed board in a warm oven. Once the moisture evaporates, the resist tends to stick tight. Try it!

Let me wrap this thing up by quoting a phrase I heard from many a PC professional fabricator: "You can't make PCs for under about $100,000!"

Dayton: Reporter's Notebook

"It was the ham radio event of the year in several ways — the new growth of the hobby was obvious . . ."

Dayton 1977 was the biggest yet, with thousands more than the organizers expected. At deadline, the estimate of attendance was well over 16,000, although ticket numbers higher than that were heard over the hamvention PA during the closing hours. It was the ham radio event of the year in several ways — the growth of the hobby was obvious as crowds six and seven deep kept the booths busy most of the day Saturday. A three hour traffic jam around the Hara Arena earlier in the day forecast the afternoon crunch. Dayton's flea market was everything it was promised to be . . . acres and acres, with waiting lines in the early hours. (The local repeaters had warned in advance that flea market types better get plenty of sleep Friday night, so they could get a good spot or catch some good deals.) They opened the flea market doors at 6 am both Saturday and Sunday!

There were over a hundred exhibitors. Many said there were more dealers than manufacturers this year, showing less new equipment than expected. Dentron Radio, for example, put off introduction of their new transceivers until fall, while Drake was ready with their new UV-3 triband VHF/UHF transceiver. The radio offers a fully synthesized FM system covering 2m, 220 MHz, and 450 MHz, 25 Watts output, plus a variety of accessories. The unit can be separated from the power supply and main section, for remoting the control head. The Drake uses a PLL system for frequency control, with digital readout. There was also the return of the Signal One transceiver, from yet another manufacturer, Signal One Corporation. The price is up to $3999.95, but company representatives say the new CX-11A is totally redesigned (although the appearance of the rig remains much the same).

One of the Dayton VIPs was Carl Mosley of Mosley Antenna fame.

There were also the new CIR transceivers, which feature digital tuning of the 80 through 10m bands. Two switches control frequency, one a fast attack, the other a slow scan rate. The size is very small, considering the fact that the Astro 200 is rated at 100 Watts output. Accessories include a station operating console, speaker, and ac supply (the CIR normally runs on 12 to 14 V dc). CushCraft introduced a new line of HF trap vertical antennas, while Dentron showed a new 1200 Watt HF amplifier (half the MLA-2500 package, but without 160m coverage) and a new tuner to match the MLA series, complete with built-in 250 W dummy load and twin front panel wattmeters for continuous monitoring of forward and reflected power.

Among the more interesting accessories introduced at Dayton was RF Engineering's DFD-100 digital frequency display for use with Collins, Drake, Kenwood, Atlas, and Swan equipment. Readout is accurate to the nearest 100 Hz without band switching or mode switching. Hookup is easy, especially for Drake or Collins gear where the necessary frequencies are available at the back panel of the radio. Spectronics showed a unique outboard device for the popular Icom 22S 2m rig. It's called the Specscan, and it does a score of things, including full scan of the 146-147 MHz band in 15 kHz steps and VARI-SCAN™ which allows full scanning control of the scan rate in either direction. Power consumption is less than 500 mA, and automatic channel lockout lets you scan past any portion of the band. All this can be done without major surgery or giving up normal operation of the 22S.

Heath had a prototype of their new CW transmitter, which matches the HR-1680 receiver, while KLM was showing off their newly acquired 6m SSB rig, a National (of Japan) import. It is similar in style to the Hy-Gain 3750 HF transceiver, which is also made by National in Japan. Atlas, aside from enjoying the high demand for their popular 210X and 215X transceivers, showed their new 350-XL transceiver, although they were not expected to be available until early summer. Robot kept a crowd with videotape of NBC correspondent (and hamvention banquet speaker) Roy Neal K6DUE explaining SSTV to a national TV audience via a Today Show segment last winter. The story covered the N6V operation during the Mariner mission to Mars and marked the first time that both ends of an amateur QSO were broadcast live on national TV. Kenwood kept everybody wondering how they could afford a new TS-820 transceiver. The icing on the cake was Saturday's visit of Neil Rapp WB9VPG, the world's youngest licensed ham. Kenwood had given Neil a TS-520 for his 6th birthday, and his appearance at the Kenwood booth only added to the crunch around the company's display.

On the whole, dealers outnumbered manufacturers, and it was clearly a buyer's market. Prices were slashed early, with some dealers complaining that it would have been better to stay home and sell their goods without the pressure of the price cuts. There were also grumblings about the hours booths were open, as many exhibitors returned to their motels with sore feet and mild cases of exhaustion each night of the hamvention. While the exhibitors were resting, convention goers were treated to dozens of informal gatherings, ranging from the annual "FM Bash," to an ATVers' session. The parties went well into the night.

The forums were well attended, with something for everyone. The biggest turnout was, of course, for the FCC forum, which proved to be a bit disappointing. FCC Personal Radio Chief John Johnston did not take questions, presumably because of that Federal Court ruling on the Commission's alleged failure to follow its own rule making procedures. The ruling ("Briefs," June *73*) limits informal comments, such as hamfest bull sessions, without a written record for the appropriate public file.

In his talk, Johnston was strongly critical of high power amplifiers, knocking *QST* for publishing a recent construction article on the subject, and terming "brazen" the sale of a 10,000 Watt linear in the hamvention flea market. Johnston was preaching QRP, and, in light of the Carter Administration's energy proposals, his warning that "the day of the over-powered bully operator" must be numbered rang especially true. (Full details of the FCC forum can be found elsewhere in this issue.)

On WARC, amateur radio advisory

"A big part of the Dayton story was what happened outside the Hara, on the roads into the city, along the interstates and in the air terminals, where amateurs flocked for transportation to Ohio . . ."

committee chairman Peter Hurd K4NSS presented a half hour long explanation of what the frequency conference is all about and how the US is preparing for it. Hurd was thin on details about what is actually happening, although there were some hints — his reference to the Jack Anderson column, and the "tremendous interest" of the civil sector in the rf spectrum as a "gold mine" over the long term. (Hurd told the forum that the Anderson column could be traced to those same interests.)

He also warned that there had been a lack of reaction to the WARC proposals. "The concrete is beginning to harden on these proposals," Hurd said, "and comments are very important." Hurd identified the key issues ahead as a definition of what criteria would be acceptable for sharing bands, and what to do about 220 MHz. "The committee would appreciate your input on why we need 220 MHz," he said, "and why we can't share it with Class E CB."

As for keeping frequencies, Hurd showed several charts illustrating how amateur radio's position has changed over the years. In 1935, for example, the amateur population dominated the stations on the air in the US, whereas there is but a small percentage of hams (as compared to other users) on the air today. Hurd put the

"I nearly drove off the road on the way home, when Dave WD8CYV drove by on his motorcycle holding both hands in the air and showing the classic 52 signal . . ."

committee's feelings this way: "We're not on the air because of numbers, but rather because of the quality of the service we provide."

He went on to warn that we have to grow up into the 10 GHz band and beyond, to look 20 years down the road and plan for the future of amateur radio. "It's a long-term investment," said Hurd, "with the viability of today's bands limited to a very real point by how convinced the decision-makers are as to how well we're using those frequencies." Hurd did not appear optimistic, in great contrast to the League official who was telling convention-goers that "WARC and Jack Anderson are under control . . . we're right on top of it . . ." Hurd's advice to amateurs worried about WARC? "Remember that every frequency is an international one — whether it be 2m or 20m, the internationals are listening." Hurd pointed out that foreign governments maintain offices in major US cities, thus opening the door to reports home on the use of virtually every band. He also noted that the next step in WARC would be the release of a 5th notice from the FCC, due out by late May.

A big part of the Dayton story was what happened outside the Hara, on the roads into the city, along the interstates and in the air terminals, where amateurs flocked for transportation to Ohio. On Interstate 90, horns would turn to CW, with "52 . . . 52," or a simple "73" exchanged as hams passed. I nearly drove off the road on the way home, as Dave WD8CYV drove by on his motorcycle holding both hands in the air and showing the classic 52 signal! But it wasn't all fun on the highways home, as one group met disaster near Philadelphia. Driving in a sports car, they mixed it up with some big trucks, reportedly killing the driver and seriously injuring two passengers.

Dayton, the city, lived up to what was advertised — the Air Force Museum was super, the motels were generally good, and the town does shut down tight promptly at 6 pm (or shortly thereafter). Getting dinner after a day's work at the hamvention proved to be pretty rough. The first night we got hopelessly lost without a radio (better not take it, I was advised, since it will probably get ripped off),

and the second night we waited in line at a restaurant for nearly an hour before catching on to the fact that the hostess needed $25 or $30 stuffed in her hand before we could get seated. We left instead.

The hamvention itself seemed to have outgrown its bounds . . . the traffic was intense, the hours long, and the crowd huge. It looks like the Dayton club is going to consider moving from the Hara next year, possibly to a fairgrounds nearby. But Dayton is still the biggest . . . it was great fun, although it may just be getting too big for its own good.

Warren Elly WA1GUD
Assistant Editor

Dayton: FCC Forum

If there was a theme in the FCC forum at Dayton, it was probably QRP. Personal Radio Chief John Johnston K3BNS offered some strong words about high power operation, even going so far as to criticize the ARRL for publishing a recent linear amplifier construction article in *QST*. Johnston warned that the day of the "overpowered bully operator" must come to an end, with more work on QRP and developing new ways to measure power. He called the search for new power-measuring devices the greatest contribution amateurs could make to the state of the art.

With FCC staffers taking notes on the sidelines, Johnston came as close as possible to covering recent rule making proposals, without crossing the line on *ex parte* comments as prohibited in a recent federal court decision. ("Briefs," June *73*.) He said the FCC staff had been "under the gun" to deregulate amateur radio by Commission order. In fact, said Johnston, that was his first job after taking over as Personal Radio Division chief. Noting that 1976 marked the relaxation of more regulations affecting the amateur service than any other single year in history, Johnston said amateur radio had turned around, with more growth than the Gettysburg FCC staff can handle.

The growth has created new problems, according to Johnston, problems that are so serious that the licensing structure of amateur radio may have to be changed as a practical matter. License applications were up 50 percent last year, at a rate of around 12,000 per month . . . that's four thousand more applications than the Gettysburg staff can be expected to process. This year applications are arriving at *3 times* the rate that Gettysburg can handle, and 13 staffers have been moved from the CB section to cover the amateur overflow. That brought applause at the Dayton forum, but Johnston cautioned that it was not exactly something to cheer about since he'd be forced by budget considerations to put the 13 workers back on CB tickets in early June.

The licensing boom may be great for ham radio, but it represents a serious emergency for the FCC. Counting repeater applications alone, there is a backlog of over 1300 waiting for callsigns. A closed season has been called on secondary station licenses, and the Commission is looking at the Novice class license as a time-consuming wrench in the works. As Johnston put it, "Amateur applications must drop off, or classes of license will have to be simplified to increase production." "Otherwise," he added, "we will sink in a sea of applications and complaints." Ironically, at that point in the forum the lights went out. Johnston remarked that he couldn't even read the jokes . . . but what he was saying was no joking matter.

The Gettysburg computer was portrayed as a red tape monster, requiring 40 different programs just to grant one amateur license! In the case of Novice tickets, the granting of a license is only the last step in a complicated process which includes checking the credentials of volunteeer examiners, certification of code proficiency, mailing of the written exam, plus keeping track of the exam papers until they are returned. Johnston put it bluntly, saying that Gettysburg soon won't be able to do both the Novice applications and all the other classes. A new computer (and the associated programs) are due next year to replace the rental unit currently in use, and some innovations are possible (like 1 x 3 for Advanced class), but the backlog remains.

Then it was on to the latest bombshell from Washington — the first new regulations from Docket 20777 (bandwidth). Johnston explained that the new limits (40 dB below 30 MHz, 60 dB above) on harmonics and spurs were a reflection of international agreements designed to replace the old "according to good engineering practice" provisions of the current rules. Johnston contends that most manufacturers can meet the new specifications with current equipment, but he warned that it was high time for amateur radio operators to start putting higher technical standards on their equipment and operations. Johnston noted that there had been several petitions for reconsideration from the ARRL and manufacturers claiming severe business consequences, but he did not speculate on how successful the delay tactics would be. (At a meeting of ARMA, the Amateur Radio Manufacturer's Association, President Dennis Had ruled out any postponement, pointing instead to an ARMA-proposed grandfather clause designed to ease the impact of 20777.)

On callsigns, Johnston told the crowd that all W/K 1 x 2 calls were gone in the 4th and 6th districts. What Johnston did not volunteer (or did not know at the time) was that the chief of the FCC's Special Licensing Division in Gettysburg had been indicted on four bribery counts for allegedly taking $100 payments in exchange for 1 x 2 amateur calls. (See "Briefs," this issue.) Johnston, noting that all Extra class licensees will be eligible for 1 x 2s in July '77, said that the major problem in the phased changeover had been allowing people to choose their own calls. Many inter-

preted that to mean no more listings of first, second, or third choices for future callsign availabilities.

Johnston also spoke about the long-awaited comprehensive code exams, which FCC officials assure us are in effect by now at all offices. At Dayton, the word was that all district engineers would be using the new multiple choice CW tests within "days."

"The Gettysburg computer was portrayed as a red tape monster, requiring 40 different programs just to grant one amateur license . . ."

There were no questions asked of Johnston, as has been traditional at Dayton, but he did remain after the forum to field some from individuals. Overall, the FCC's most important man (from an amateur view) left quite a few questions unanswered, at least from the podium. But there were enough strong statements in his remarks to give you the feeling that deregulation and more changes in the amateur service can't be far away. Prime targets seem to be power amplifiers and the licensing structure.

De WA3ETD

PERSONAL SAFETY

More and more hams are becoming active on UHF. If you don't believe it, check out the advertising in the pages of *73.* KLM and VHF Engineering are two notable firms that deal almost exclusively in VHF and UHF gear. The number of outfits that provide some sort of 2m gear is amazing. It has been said that at least fifty percent of the active amateur population is on 2m; I don't doubt it for one moment. The trend in the VHF/UHF tinkerers' community is to reach higher and higher in frequency. At least one progressive company, Microwave Associates, has responded by providing a specially designed microwave transceiver for the ham market. (The product is the 10.5 GHz Gunnplexer, discussed in May's New Products section.) If you are not an OSCAR satellite fan, listen in on the 2m downlink some evening if you have a tunable rig for two meters. Any old omnidirectional antenna will do — those Mode B signals are pretty strong! After chastising yourself for not being on OSCAR, recall that each of those two meter signals was the result of a 432 MHz uplink signal, and if 432 is not UHF, I don't know what is! Many OSCAR users probably do not consider themselves UHF enthusiasts, and are more concerned with the communications aspect of their hobby. The point of all this is that daily more and more hams are using UHF. This trend will most certainly continue as more manufacturers jump into the ring. And don't forget the new OSCAR launch this fall — the one with a 2m uplink and 435 MHz downlink — the first bird to actually use an amateur satellite frequency!

As with any new band, there are precautions to observe. Remember the first time you were on two, and ran 250 feet of war surplus RG-58 up to the old horizontal beam? Didn't get too far, huh! Not only does UHF have its share of technical problems, but also there are questions of personal safety that must be observed.

Most hams have seen or used the now familiar "microwave oven," a device that uses high frequency energy to heat organic material from the "inside out." The relationship between heating effect and rf frequency is not agreed upon by the experts, but one thing is for sure — UHF energy from an amateur transmitter in the 420 MHz band and up can be dangerous in some instances. The problem results when tissues are heated by the radiation faster than can be compensated for by normal blood flow. The eyes are particularly sensitive to UHF radiation. The experts also do not agree on what "power density" can cause damage to human tissue and at what frequency the power must be applied, etc. Industry currently accepts a standard stating that a power density of 10 mW/cm^2 is safe, that is, at the point of exposure the amount of energy passing through a square centimeter in space is less than 10 mW. There has been considerable pressure from medical and research groups to lower that figure, as there has been evidence that eye damage can occur at considerably lower power densities. No one knows for sure. For additional information concerning the effects of microwave radiation and research into the problem, refer to an excellent series, "Microwaves," by Paul Brodeur, that appeared in the Dec. 13 and Dec. 20, 1976, issues of *The New Yorker* magazine. Back to amateur transmitters!

It should be obvious that any amateur UHF transmitter capable of generating power is potentially dangerous. Power density is enhanced by beam antenna systems, dishes, horns, or whatever device is employed to focus the transmitted signal. One should never needlessly expose oneself to UHF radiation. Do not stand in front of a beam operating at 420 MHz and especially avoid exposing the head. Under no circumstances look into the end of a horn or waveguide antenna while the transmitter is operating. Why take a chance when so little is known about the subject of heating and neurological effects?

Microwave Associates Gunnplexers are bound to become increasingly popular. I have been doing considerable experimenting with a pair of these devices and employ a simple method to avoid exposure. The mobile "radar detectors" which are currently transcending CB radios in popularity are broadband devices and will respond with a whistle or whine to almost *any* microwave radiation below 20 GHz. I keep an el-cheapo variety detector activated in the room when experimenting with Gunnplexers, and does it go off when the 'plexer is fired up! It sure keeps me aware when microwaves are present, even though the devices are "aimed" away from myself and anyone else around. One night, Rich Force WB1ASL, *73*'s publications editor, and myself ran a test with a Gunnplexer and the radar detector. The detector went off at distances over 200 yards away from the source of microwaves, and I ran out of space to back up. If you don't feel like springing for a detector, build a simple device using a UHF diode — be smart!

DOES THE FCC KNOW ABOUT MICROWAVES?

A silly question, you say! I received a call late last Friday from a concerned research group on the West Coast. It is common knowledge that a new Citizens Band is proposed for the 900 MHz region. (Microwave ovens function with energy in that band!) Some people are concerned that personal safety may not be the ultimate goal of the Personal Communications Department (FCC). Imagine running 100 Watts into a well-designed beam at 900 MHz. Could get warm, and that's what we are concerned about!

This morning I called Personal Communications Engineering and talked to Mr. Will McGibbon. It turns out that the Chief Engineer, Mr. Ray Spence, was concerned enough with the problem of biological radiation effects that he asked Mr. McGibbon to research the problem. The FCC is well aware of potential problems, and I was assured that the biological question will be addressed before any new bands are opened for public use. There are tons of literature and reports to wade through, culminating in an international convention to be held this fall. Hopefully the question of "radiation standards" will be resolved. There is considerable evidence that the 10 mW/cm^2 standard may be unsafe, although much of the supporting research was conducted by the Russians. Many of the experiments have not been able to be duplicated. I am personally interested in this subject. All UHF experimenters should be. This column will pass along information as it becomes available, but for a primer, try *The New Yorker* articles.

AUTHORS TAKE NOTE

The editorial staff at *73* is busier than ever! Everyone on the *73* end of things has at least two functions, ranging all the way from "pasting up" articles to insuring that authors get paid for their work as fast as possible. The phone also rings several times a day with calls from authors wondering what the situation is with their articles. Possibly a bit of explanation about our system will be helpful at this time.

Articles arrive at a rate of four or five a day, on the average, and are opened and dated by me. Hopefully, within the week they are read, and, if accepted, priced. Rejected articles are immediately returned with no funny business. At the time of acceptance I fill out and mail a postcard indicating acceptance. The card states that "a check and author's proofs are forthcoming." It should say ". . . forthcoming in four to six weeks," as our production and financial people work on a monthly cycle. Once the card is received, you can expect a check in about a month, maybe sooner if it's the end of our cycle, and author's proof sheets, which indicate how your article will look in print. It is very important to carefully check the proof sheets for errors, especially in the schematics and diagrams. Your integrity is at stake as well as ours! Please do not phone two weeks after sending your article wondering why your check has not been mailed — it's on the way! As you know, *73* pays authors upon acceptance, which is unusual in this field. We try our best to publish all material as space permits!

Writing for *73* is easy and fun! There is no better way to partially finance your hobby and become published at the same time! If you have been sitting on a pet project, let us know about it — share your inventiveness with others. Send an SASE for a copy of "How To Write For *73*," which outlines the rules to follow when preparing your manuscript. Please, NO handwritten material. If you can't type, have your article typed — it's cheap. After reading for six or eight hours every day, you would understand why typing is important — thanks!

COMPUTERMANIA

The biggest hobby computer trade show of them all is being held on August 25-27. The place is the Commonwealth Pier in Boston. Sponsored by *Kilobaud* (you have a subscription, right?), the show will cater to microcomputer hobbyists, calculator freaks, the mini crowd, and the small businessman requiring an insight into small systems. All the micro systems will be represented on the exhibit floor, and a steady stream of forums and demos by the manufacturers will be offered to keep you posted on the micro industry. Mark your calendar, and stay tuned to *73* for information as it becomes available.

Executive Editor

Jim Beedle W9NIN and Art Reis WB9YOB have prepared a guide on how to write your congressmen and senators in support of the Goldwater RFI Bill, and its counterpart in the house. They suggest you handwrite your letters, be concise, and stick to just one issue — S-864. See "Briefs" for a listing of key senators. — Ed.

Make S-864 Law!

WHY S-864 MUST BE MADE LAW

I. Constitutional Reasons. The Constitution was designed, among other reasons, to protect what the Declaration of Independence referred to as "certain inalienable rights," including the rights to "Life, Liberty, and the Pursuit of Happiness." And, the First Amendment goes a long way toward fulfilling that protection. Precedent and common sense have further established that "one's rights end where another's nose begins."

As long as the activities of one are not at fault in denying the rights of others, as mentioned above, there is nothing truly illegal about them. Specifically, amateur radio operators and Citizens Banders, as long as their transmitting equipment is designed, adjusted, and filtered properly for the prevention of RFI, have every Constitutional right to be on the air. Likewise, their neighbor has every right to watch his TV or listen to the radio or stereo in peace, as long as he doesn't infringe on the rights of others (i.e., too loud for the neighbors). However, the makers of such home electronic equipment have misused their right to pursue their happiness by making their wares as cheaply and as shoddily as possible in certain respects, while selling them for whatever the market will bear. This is not inherently evil, except insofar as their pursuit of happiness infringes upon the rights of both the consumer and the radio operator/hobbyist to enjoy their separate avocations in peace and harmony in the same neighborhood. Then it's time to do something about it. With 20 million CB sets and 300,000 amateur radio sets out there, they have to put them somewhere. And that includes your neighborhood. The personal communications explosion says it loud and clear: The time is now to clean it up!

II. The Government. It's time to save the FCC. Like many Federal agencies, the FCC is underfunded, understaffed, and overworked. In 1974, the Commission received over 40,000 RFI complaints from consumers. When these were carefully analyzed, ninety percent were found to be the fault of the design and/or construction of the equipment interfered with, and not of the transmitters involved. In 1977, the FCC expects to receive 200,000 of these complaints. Considering how small the Commission's kitty is, couldn't some of that be used for better purposes than chasing down RFI complaints? We think so.

III. The Consumer. Joe Consumer is a babe in the woods on this issue, and in one major respect, he is being ripped off. But, unfortunately, he is blaming the wrong guy. When Joe spends a lot of his hard-earned money on a new TV, stereo, or whatever, he almost expects that it be made by God, and that it is perfect. Well, we have news. It is not. If the amateur radio or CB buff down the street tears up the picture and/or sound, Joe Consumer's logic says: "It didn't happen before he got on the air. It must be his fault." Joe doesn't know what makes his little box work. All he cares about is whether the picture or sound is there, in good quality. He doesn't realize that it takes something else besides what meets the eye or ear to make his equipment a truly quality device. But, for the money that they've just extracted from him, the manufacturer of that equipment should have seen to that end of it, so that Joe won't have to worry about it. We think that it's time he did.

Oh, yes, the television manufacturers have long offered filters, free, to anyone with a TVI problem. But they've never made any publicity about it, so chances are good that Joe knows nothing about it, or how to get such a filter. If in the off chance he does get the filter, then why does Joe have to pay the $20 or so installation fee, after shelling out all that other dough to get the set in the first place? And what if the problem were caused by lack of shielding, which a filter can't fix? What does all this tell you about how the manufacturers feel about their products? And, what about the RFI problems of other types of consumer electronic equipment? What's being done for the consumer by them? Do you see why we're fighting to make the manufacturers clean up their act, before the consumer buys it?

IV. Radio Operator/Hobbyist. He's in the vise here. When he operates, even if he's clean, he's hated by someone in his neighborhood. Joe Consumer casts him as the villain in this game, when 90% of the time he's not. Bill Operator may not be interfering with his own TV or stereo (which can prove that he's "clean"), but that cuts no mustard with Joe Consumer down the street. If this sort of thing keeps up, Bill Operator may face some nasty situations, such as vandalism against his equipment, or worse, local nuisance ordinances, local tower bans, or a total ban on his operations by local authorities. And, nine chances out of ten, it's not his fault. It's not fair, and we believe that a court test would eventually support Bill's right to operate in peace. But, must we go through that? No . . . not if S-864 passes.

V. The Manufacturer. At least one manufacturer now puts a high pass filter at the front end of its TV sets. Hurray for them, whoever they are. But, for the rest, it's still business as usual. Not that any of them haven't done something about this. Another major TV manufacturer has researched the cost per degree of RFI protection built into a TV set. Our sources tell us that it comes out to about a dollar a set. Obviously, that makes such protection economically feasible for Joe Consumer. So, why don't they? Because they haven't been told to, yet!

Over the past few years, metal shielding has disappeared from the American TV set. Its place has been taken by plastic. Couple this with the coming of the transistor, which is much more RFI-prone than vacuum tubes, and you have a major RFI problem. Add in poorly designed circuitry, built only with low cost in mind, without the proper design to get rid of strong adjacent local signals (such as Bill Operator), and maybe an old, corroded antenna with lead-in, and you have the makings of disaster. Period.

You know, there are other countries that don't put up with this sort of situation. Japan and Germany require that all home entertainment equipment made for domestic sale be RFI resistant. There, the RFI problem is but a tiny fraction of what it is in this country. And the cost to the consumer is little more than it is here. If it works there, it will work here.

And the manufacturers know that. And they will continue to fight such improvements, just as they did in 1964, when the All-Channel Set Law was being debated. The manufacturers screamed that the prices of TVs would be pushed out of sight if the law passed. It did pass; the price rise was very moderate. The situation is no different here, with S-864. Only the stakes are higher. So, why not support it?

VI. The Broadcaster. Jim Broadcaster is involved in this fight from several angles. The low band VHF TV broadcaster, particularly, has a problem with local signals from six meter amateur radio operations, and in some cases, signals from the FM broadcast band may wipe him out. If a certain TV's i-f stage is unshielded, a strong local signal may enter there and wipe out all reception of all TV channels. AM broadcasters get it from two directions. Spurious radiation given off by nearby TV sets operating with poorly designed sweep circuitry and wide-open cabinets clobber their signals in the fringe areas of their coverage — or even closer in. Meanwhile, the AMer himself may interfere with a PA system being used near his transmitter site.

All broadcasters are affected if the radios or TVs receiving their stations are blown away by a strong local signal coming into the audio stages of the receiver. Then the local signal will wipe out the broadcaster's audio, and Joe Consumer may end up playing cribbage rather than listening to your ad messages.

A major problem for the AM broadcaster is industrial noise, and we believe now that much of it is caused by radio frequency emissions from home TV sets. It never occurred to you, did it?

Remember: As long as the amateur radio operator or CBer is running a "clean" rig, he is not the one to be condemned. Go after the guy who built the TV, stereo, whatever is being interfered with. He's ripping you off! Support S-864.

WHAT BILL S-864 IS

It is simply an amendment to the Communications Act of 1934, which allows the FCC to set standards for the manufacture of consumer electronic equipment, with regard to its susceptibility to interference from nearby transmitters which are properly licensed, designed, and operated. That means that the passage of this legislation into law is only the first of two steps needed to make this whole problem of RFI go away. Later, we will offer, in petition form, a set of standards for the FCC's consideration, and again we will ask your support to put an end to this problem once and for all.

TO ALL AMATEUR RADIO OPERATORS AND CBERS

S-864 must become law if we are to remove a major threat to both personal communications and the right to view and listen in this country. Therefore, you are strongly urged to (1) write your representatives in Washington, demanding their support of Bill S-864 and its House counterpart. Feel quite free to use any and all arguments used here. Your own words will help. And (2) pass this information on to a friend, neighbor, or relative.

Remember, if you don't support this legislation, and it fails, and you later have an interference problem with your new, TV, stereo, amateur or CB rig, you have no one but yourself to blame. Don't put it off, write to your elected representatives now!

The Duty

With news of a US Customs Court decision ordering higher import duties on Japanese imports (see "Briefs"), the stage has been set for another round in the debate over foreign manufactured electronics goods. But not all American companies favor higher import duties, especially those who use foreign components, as illustrated by this news release from National Semiconductor. — Ed.

Mr. E. Floyd Kvamme, vice president and general manager of National Semiconductor Corporation's semiconductor division, appeared in Washington on March 15, 1977 to testify at US International Trade Commission hearings. The ITC is conducting an investigation for Congress regarding the possible economic repercussions of a proposed duty on imports of digital watches and components.

Mr. Kvamme spoke on behalf of the Western Electronics Manufacturers Association (WEMA), a trade association of firms that account for most of the high technology semiconductor devices used in digital watches as well as in computers and modern electronic products. National is a Santa Clara, California based company that is one of the largest manufacturers of both semiconductors and of the finished watches.

The bills under consideration by Congress would more than triple the duties on digital watch components assembled for American manufacturers at offshore locations. "Both the conventional watch industry and the new digital timepiece industry sustain US production and employment by shifting certain activities offshore," Mr. Kvamme said.

According to WEMA, the levy on imports of the solid state watch modules used in digital watch manufacture is supported chiefly by US companies that make conventional (non-digital) watches. They favor the tariff increases to protect themselves against stiffening competition from increasingly popular low priced digital watches. Because of lower production costs, many American semiconductor and digital watch manufacturers have located some assembly operations in plants in the Far East. Mr. Kvamme characterized the situation as "a marketing problem between different segments of the US timekeeping industry," rather than a straightforward case of foreign manufacturers flooding the US with cheap products.

If the tariffs were increased, the US companies would probably be forced to close these offshore plants, and the growing availability of inexpensive digital watches would be reversed. Adverse economic effects would be triggered, culminating in the loss of thousands of jobs in the US semiconductor and electronic watch industries.

"In 1976, the US semiconductor industry recorded annual sales of $3.4 billion and employed over 100,000 people. The manufacture of integrated circuits and displays in the US together with the final assembly of digital time-pieces in this country will, and in fact has, provided new employment opportunities for thousands of Americans. If HR 14600 were enacted, however, not only would new job opportunities be lost, but existing jobs would disappear."

Mr. Kvamme pointed out that many of the electronic circuits and numeric displays used in foreign made watches and other electronic products are produced by US firms such as National Semiconductor. One danger of the proposed import duty is that it would probably cause a retaliatory reaction from foreign countries who are now heavy importers of both digital watches and electronic parts from the US. Many foreign governments are trying to encourage the development of their own semiconductor industries.

"US companies, if allowed to compete fairly on the international scene, are expected to increase their market share during the remainder of this decade to 68% of the market, or $7.2 billion."

Mr. Kvamme noted that the low prices of digital watches (about 75% of all solid state watches sold for under $25) allowed the US to capture about three-fourths of the world's market for digital watches in 1976. He predicted that the demand for digital watches would be about two and a half times as great by the end of the decade, resulting in a significant increase in jobs.

The overwhelming supremacy of American electronic circuitry in the world market has resulted in a highly favorable trade balance for the US semiconductor industry. The US posted a trade deficit of $5.9 billion in 1976.

"The semiconductor industry, if allowed to operate with maximum freedom from artificial trade barriers, could change the American watch industry from one that operates with an unfavorable balance of trade to one with a favorable trade balance."

Mr. Kvamme concluded by saying that the proposed tariffs would "hamper a growing and dynamic US industry, will result in higher prices for the US consumer, and will produce retaliation on the part of our foreign trading partners. It will result in the loss of both existing and future US jobs."

Breakdown

"Breakdown in communications" is a catch phrase heard about all sectors of life. Is it afflicting hams? As you listen to your favorite band the QRM may immediately convince you that more and more people are talking. Are they enjoying it less and less? Since the breakdown in communications in families, between husbands and wives, among friends and in various other parts of society is mentioned so often, it is no wonder that many hams are feeling unsatisfied with their QSOs. And that other demon, the "generation gap," takes its toll here, too. Oldtimers (of whom there are thousands) feel uneasy talking with someone whom they feel knows everything about solid state and computers but really has no love of ham radio because he knows nothing about the old days of homemade equipment, class B modulators, Super Gainer receivers and wire antennas. The younger ham (of whom there are also thousands) feels uncomfortable talking with someone who yearns for the golden days of the '30s.

The ham population is further fragmentized by special interests: TV, phone, CW, RTTY, FM, phone patching, DXing, etc. This is clearly indicated by band subdivisions if one is blind to the poorly concealed contempt that some members of one group often have for members of another group. The barriers are also noted by the various closed repeaters as well as the many nets that occupy the lower bands. The unwary intruder is often told to get out much as a bouncer would throw out a stranger at a Frank Sinatra wedding.

While the modern situation is much more complex, its roots are found in the special interests which were felt from the very beginning of ham radio. There were those who enjoyed rag chewing and it didn't matter much if their Ford-coil spark set only reached the guy on the other side of town. The distance, or DX, mattered very much to others. Their thrills were measured by the mile. Still others felt guilty if they were not of public service, and their pleasure was handling messages free of charge.

Seeing that there have been different aspects with varying appeals from the start, does this mean the FM repeater man, for example, and the lower band DX fan will never have much in common? Not necessarily. But neither does it mean that we are all going to develop an overwhelming interest in one mode of transmission and one amateur band. What is possible, and what our goal should be, is better communications between hams as humans, as people, better communications involving the individual as a person.

Communications is an art, it is said. It basically means expressing yourself and your ideas clearly to another. Sometimes, of course, we do not want to express ourselves too vividly. Guests are invited into the living room, so to speak, but not into the rest of the house. Guests are envious of the new furniture (the new radio equipment) a fellow ham has just bought, but the host doesn't say he still owes ten payments on it or that he and his wife had a terrible family fight because he bought it. But what about the things we *do* want to express?

Enthusiasm is the best vehicle to get them to their target. There is no other ingredient which will so help us get to the heart and mind of our fellow man. It views things through the eyes of a child, and with the heart of a lover. It acts as a self-releasing power and helps focus the entire force of personality on a subject. It lifts your listener into the clouds with you and makes him see the thrills, mystery, romance and fascination which has captured you. It transports your audience from the humdrum into a new world of wonder — your world.

But remember that communication is a two-way road. It is not an attempt to impress another with how great you are or with the expensive equipment you are using. Let's say, for a ham, it's an invitation to another person to share some delights, to have some fun together for a few minutes. Its aim is to encourage two people of similar interests to confide in one another and get to know one another, to build friendship, to create what the Greeks called phileo, fraternal love.

Sincerity comes into the picture, too, then. This helps us to see that the enthusiasm mentioned is not the empty backslapping of a high pressure salesman which perhaps has its parallel in the fancy warm phrases of friendship printed on some QSL cards. If it really was a pleasure to talk with another ham, let us be sincere enough to *write* it on our QSL cards rather than have it printed. Don't the Christmas and birthday cards that you appreciate the most have a hand-written line or two on them? Don't those few phrases truly mean more to the recipient than whether the card cost

twenty cents or a dollar?

Stereotyped QSOs have been condemned so many times in so many columns in ham magazines that only a few words are necessary here. What is bad is not necessarily that we say more or less the same thing to each new station with which we talk. What is bad is that we say the same thing everyone else is saying. How boring if the fellow you're talking with at the moment says essentially the same thing the two dozen hams before him said! Let's spice things up with a little originality.

Yes, of course we generally discuss the same things. We all sob over the poor band conditions, mention the equipment we're using and the antenna we have. So, where's the originality? Well, suppose you find out the other fellow is using the same kind of equipment you are. Why not tell him if you've had a problem, what the symptoms were, how you identified the bad component, and so on. This little bit of information is sure to interest him, and he'll tell you if he's had the same problem or a different one and perhaps pass along something that can help you. Or, have you used the equipment in an unusual situation? Is there some feature of the gear you particularly enjoy? Or something that annoys you?

Other ideas? Well, is your shack in an unusual location or an unusual room in the house? Are you using an alternate source of energy to power your rig? Made any modifications to your equipment you're happy about? Helped anyone get his ticket? Offered to give a talk on ham radio to the local grade or high school and had any takers? Any results? Other hobbies in the family? Your occupation?

With the transistorized preamplifiers available, some hams are using antique microphones, and anyone can use an antique telegraph key. If you enjoy such things, let the other fellow know about it. How you got interested, how old the antique is, who used it before – is it all original, etc. If you have a conversation piece in your shack, then talk about it.

Regardless of where you live, mention it by name as well as saying near such and such large city. Many people travel extensively these days. I was talking recently with a Kentucky ham and had to ask three times where he lived. Finally he confessed, "Pikeville." He was amazed that I had visited there several times, and we had quite a talk. Another fellow was in Crossville, Tennessee, but I learned this only by being insistent. Neither of these men could believe that a ham in Peru could be interested in their exact location. On the other hand, I am surprised at how many I talk with who have visited Arequipa. Those who have always tell me about it and ask what part of town I live in, and we usually have a nice visit. Did you know that Arequipa is 450 years old? Has one of the oldest medical universities in this part of the world? Enjoys a climate unsurpassed anywhere?

How old is *your* town? What made people settle there? What are the main industries? Were you born there or did you move there? Would you like to leave? Why? Where do you want to go? Why? Besides the temperature, what else can you say about the weather? Is it raining? Is that good? How is the weather affecting your lawn or garden? What do you see from your window?

What about your family? Do you mention them on the air? A fellow down here in South America was telling me about his equipment one morning when he interrupted himself. He was back in just a moment saying, "That was my wife. I'm always up before her and at my radio. Then when she gets up she fixes me a cup of coffee and brings it to me and gives me a kiss. We've been married 20 years, and she kisses me good morning every day." I felt I had been admitted into the family circle, and that I knew him better. I complimented him on such a loving companion, and we enjoyed a chat about marriage. When we signed off he left me wondering what I'm doing wrong that I don't get a kiss every morning. I'll never forget him.

Some hams on the air for years seem to still have a bit of "mike fright." Perhaps it is because they have concentrated on the technical things of life and are unsure of their grammar and pronunciation. My advice to them is to forget it and enjoy talking. Dizzy Dean was a huge success as a baseball TV play-by-play announcer partly because of the things he did to our language. "He slud into third" was the first expression that caused comment. Later he varied "slud" with "slood" and then one afternoon he came up with, "The trouble with them boys is, they ain't got no spart." When the color man asked at the end of the game for an explanation, Dizzy said, "Spart is pretty much the same as fight or pep or gumption. Like the 'Spart of St. Louis,' that plane that Lindberg flowed to Europe in." If you enjoy something as much as Dizzy Dean loved baseball, your language will not matter much. People will be thrilled to hear you talk about it.

A word of caution for DX contacts. Remember that for most of those operators English is a second language. Speak slowly and distinctly. This is more understandable for them at any time and is more intelligible under poor conditions. Avoid slang and idiomatic expressions and keep it simple.

Your accent shows up on CW as well as phone. I will always remember the Novice I worked on 15. His Morse was about the worst I have ever been able to copy. Of course, he wanted a QSL. I slowly sent him the suggestion that he slow down, that he should try to improve his code and told him I would like to have a couple of IRCs for the airmail QSL. He sent me a hot letter telling me he could send better than he could receive and that he had a certificate for copying W1AW at 20 wpm. He further thought I was a crumb for asking for two IRCs for the QSL. He concluded by stating that the keyer he was using was out of adjustment, and if the code he sent was not readable, it wasn't his fault!

So, if you're on CW, whatever you are using to send with, be sure it is properly adjusted and that you feel comfortable with it. And if you're on phone, turn your mike off before you clear your throat, cough, sneeze or shout at the kids in the other room.

A comment about profanity might be in order. It is against the law, in the first place. And it is a sad commentary on a man's masculinity when he feels that he must show it by his choice (?) of words. But considering that a night doesn't pass without some of these words being heard on TV, perhaps it is too much to suggest that they be eliminated. But if one has to work one or two into every transmission, I personally can not help but feel that he has a limited vocabulary. Sometimes, perhaps, nothing else fits. Anyone who enjoyed the hours long movie "Gone With The Wind" could not help leaving profoundly impressed by Clark Gable's concluding word. Would the FCC, then, overlook every four to six hours one really appropriate "damn"?

Listening is the other half of conversation which, together with talking, makes up communication. If no one listens, it is useless to talk, a point not always realized by those talking. And listening doesn't just mean separating the words from the QRM. It involves understanding or interpreting both the literal meaning of the words as well as the speaker's intention. If someone says to you, "Why you old son of a gun!" the phrase is an insult, but the warmth and affection in the voice indicates exactly the opposite.

Most people, including hams, are not very good listeners. We generally talk more than we listen. And while we're supposed to be listening, most of us are making mental notes preparing something to say just as soon as the other fellow shuts up and gives us the chance. Learning to really listen is not difficult, just rare. Usually considered a passive thing as when listening to some favorite music, listening should be a quite active thing . . . as a real jazz buff carries the melody in his head while listening to the group improvise with various counterpoints, themes and melodies. A stream of words entering our ears must be interpreted not only by our minds as to literal meaning, but by our hearts, too, for the often more important meaning. How close can you come to what the other fellow is really trying to say? Speech is often full of symbols, and the well-trained listener can identify them immediately. The aim of careful listening is to actively seek to discover how the other fellow feels about what he is talking about and what kind of person he is.

And how do you conclude a contact? If you listen, you'll see that many hesitate, stumble, tie the ribbons on, have a final and then a final-final, all giving the feeling they want to sign off but don't want to offend the listener. Have you noticed the same tendency among some of the guests who visit in your home? They get ready to leave, get to the door, and then stand there talking for fifteen minutes. Let's learn something from the "good buddies" on CB. When they say, "I'm gone," they are *gone*. So, let's not rush, let's say what we want to, let's give the other fellow a chance to talk and really listen to him, but when we sign off, let's shut up and not drag it out like a soft-hearted lover who has decided to break it off but then can't bring himself to say the fatal words and keeps on talking, talking, talking. I'm gone.

George Brumley OA6CV
Arequipa, Peru

Mauritius

Pete Smith K4FOK has recently completed a DXpedition to Africa that was intended to put Zambia on the air in a big way. But it was not to be . . . as we learn from Pete himself, via the West Coast DX Bulletin. *– Ed.*

As must be abundantly clear by now, I did not get on from Zambia. My application for a license was turned down with the explanation that the Zambian government does not license foreign amateurs for stays of less than one year. My appeals of this decision, and requests for any sort of temporary permission to operate, went quite high up . . . but were all denied.

Anyway, on to Mauritius where it was a different story. I was issued 3B8DT, largely on the strength of my US license, though, as I understand it, the Mauritian authorities appreciate it if the foreign applicant has some sort of Commonwealth license. I would certainly have a UK reciprocal license

in hand if I were doing it again.

I was able to set up at a beautiful hotel on the northwest coast of the island, with a clear shot toward the US. Unfortunately, I did not arrive until late on March 17th, had business all day (the 18th), and finally got back and fired up the equipment for the first time after midnight (local time) — about 2000Z on March 18th.

The first twelve hours of the ARRL DX Test were an utter disaster with something like seven contacts, but things picked up after that. Good conditions on 15, fair on 20, and 40/80 mostly not so hot as much of the time I was in daylight and the QRN was over S9. I think I shook a few people in the waning hours of the contest answering their CQs on forty.

The total reads 583 US contest QSOs without duplicates. There were about 15 with the West Coast and about 500 with non-US stations, these during periods when the bands were not open to the states. All but thirty of the QSOs were CW. Unhappily, I had to pack the gear and head for home on March 21st, and I did not get the chance for the phone operation I would have liked to have had.

Although I was unable to get on from 7Q7 Malawi, and had understood that all operation there had been suspended back in June 1975, while listening one evening on twenty I heard 7Q7LW working through a pile of JAs. She gave a box number in Zomba as address, and there was no reason to think that she was not genuine.

Thanks to the Northern California DX Foundation for equipment and other assistance, including QSLing. The DX Foundation tells me that they intend to QSL every contact through bureaus as soon as the QSL cards are ready.

Pete Smith K4FOK/3B8DT
Reston VA

Pitch

In light of recent efforts by Jack Anderson to discredit ham radio, many amateurs replied with the other point of view in letters and telegrams to their congressmen and hometown newspapers. Some, like Larry Schwartz WB3DBI, took another route — in this case a high school newspaper. — Ed.

Last year, over 6,000,000 new CBers received their licenses, bringing their total number to over 8,000,000. But throughout the US there exists another group of radio operators.

In contrast, they form a much smaller group, about 300,000. Whereas CBers run four Watts of power, these people legally run as much as 2000.

CBers operate on 40 channels while the other operators have literally thousands. While most CB equipment costs between $100 and $300, the other group can pay this price or invest thousands of dollars in a station. The Federal Communications Commission (FCC) also permits this other group to construct their own equipment if they so desire.

Who are these other people? They form a group of radio operators commonly known as "hams." Hams communicate all over the world using Morse code, voice, and Teletype. The FCC even allows hams to use television to communicate. Additionally, where facilities permit, hams can use their radios to place local phone calls while remaining in their cars.

With all of these privileges, why doesn't everyone become a ham? Mr. Donald Smith, an electronics teacher and a ham radio operator, explained, "Ham radio shows technical knowledge and not everybody has the desire to go into it."

To qualify as a ham, one must first pass a Morse code test and then pass a test dealing with electronics and radio law. Passing tests of greater difficulty qualifies the applicant to operate at more frequencies. Put another way, they receive a larger portion of the radio spectrum.

Junior Ari Hirschman, a ham radio operator, told why he got started: "I liked the feeling that I would be able to talk over such long distances and sometimes be able to do it with equipment I built myself. I also like the technical aspects involved."

Sophomore Paul Schmidt, also a ham, gained an interest in ham from his brother. "When I first became interested, I hardly knew anything about radio and it sounded like a neat idea."

Paul said that recently on the air he met somebody who challenged him to chess. The whole game was conducted over the radio.

Hams also perform many public services. During the Guatemala earthquake in 1976, hams went into action. Hams flew to Guatemala and, using their equipment, sent reports back to the US about the situation there. Many times during a parade hams will monitor the parade route and keep in touch with the police.

Hams also form many on-the-air groups. These groups may handle and relay messages, such as those during a disaster. The groups may also discuss electronics or play games. Many hams even do their homework over the air.

Recently, courses for people interested in studying for their ham licenses have grown. The Montgomery (MD) County Department of Recreation offers courses providing the electronic theory needed to pass a ham test. Interested persons should phone 468-4050.

Respect

Your personal help is requested in achieving more harmony in our overcrowded 20 meter phone band. Working DX is the major interest of many worldwide amateurs — SSTV, net operation (handling important and vital traffic), and, then too, just plain rag chewing enjoyed by many, many hams.

Let's examine the space allocated for SSB on 20 meters — 14,200 to 14,350 kHz. Yes, only 150 kHz! It is a well-known fact that most DX is worked at the low end of the band, 14,200 kHz and up. Let's arbitrarily suggest 10% of the 150 kHz for DX. This would give the DXers 14,200 to 14,215 kHz. The 14,230 kHz + or - 3 or 4 kHz is the SSTV area. How about 10% for nets and traffic? This group is pretty well established in the area 14,300 to 14,315 kHz.

Irate SSTV, DX, net and rag chewers continually harass SSTV, DX, net and rag chewers with carriers, tapes, CQs and other noises. Effective, yes, but definitely not the answer to the problem. The resulting QRM renders the frequency useless to all, and everyone loses. Tempers flare, anger, irritation and frustration prevail. Our hobby is degraded. This could all be avoided if amateurs used better judgment in selecting the proper frequencies for SSTV, DX, nets and rag chewing.

You will note that I said above "arbitrarily" when I suggested the frequencies for the various groups. You could never reach a definite agreement among all the hams on 20 meter phone, but this could be a start!

Eye Bank

In the United States, eye banks are served by a network of volunteer ham radio operators. Three hundred and sixty-five days every year without a holiday, this rapid nationwide network stands ready to flash the news of emergency requests for eyes, and where eyes are available.

In emergencies, from fire, a laboratory explosion, an auto accident, certain acute infections, where immediate corneal transplants are necessary, the Eye Bank Emergency Radio Network serves as a means of saving the eyesight of hundreds of people. It assures that a donor's eyes will be rushed anywhere that an emergency exists.

The Eye Emergency Net, a true public service net, has been in continuous operation for almost fourteen years through the untiring efforts of a distinguished and highly dedicated group of amateur radio operators.

Briefly stated, the purpose of the Eye Emergency Net is to handle information regarding the need for and the availability of human eyes for emergency corneal surgery for the various eye banks throughout the country. In accordance with this simple purpose of trying to be of assistance in preventing the loss of sight in an emergency situation, it has been decided that henceforth only emergency needs for eyes and the availability of eyes will be listed and carried on the several Eye Emergency Nets by the net control operators.

Each amateur radio operator is requested to so inform the eye bank he or she represents of this policy of listing only emergency needs and/or the availability of eyes. This will improve the efficiency of the Eye Emergency Nets and will eliminate needless repetition of unnecessary and

useless information as has crept into the operation in the past. Naturally, each amateur radio operator should keep in close contact with his or her eye bank to keep them informed of emergencies listed and/or availabilities. In this manner we can carry out our avowed purpose of helping to save sight in emergencies and, in addition, operate more efficiently with less time occupying crowded radio frequencies.

The policy stated on this page is to aquaint my fellow amateurs with the Eye Emergency Net. I am a net member representing the Midsouth Eye Bank of Memphis, Tennessee. There are several nets which meet every day of the week, every week of the year. The only exception is the first one, which doesn't meet on the weekend. (All times are EDST.) 0600-3970 kHz; 0645-3970 kHz; 0800-7294 kHz; 1845-7294 kHz; and at 1900-3970 kHz. I check into the net that meets at 0645 on 3970 kHz. I have found that I can meet this net and be on the road to work by 0700. It only lasts about five or ten minutes. I also call the eye bank and leave a message with the answering service as to the need or the availability of donor eyes. All this and I am still on the road to work by 0700 and usually earlier than that. As you can see, the net is quick and to the point, and serves a great need to the Eye Banks of America. Can you find five or ten minutes in your busy schedule to help a person to gain back his eyesight? If not, close your eyes and walk to the refrigerator, pour yourself a glass of milk, then turn on the TV, sit back and relax.

Light

A recent editorial in the March, 1977, issue of *Ham Radio* magazine caused me so much pain that I feel compelled to take pen in hand and do something about it. The author has a good topic (the 40th anniversary of the invention of the klystron) and he traces its development in a well-informed manner. His summary and call to action, however, fall far short of what could be a noble point. The editorial writer calls for more activity on the microwave frequencies to protect our allocations in light of WARC '79. This conclusion is less than worthy for three reasons. First, nobody in positions of importance would know, nor would they care, if amateur activity on 10 GHz increased ten times over. Secondly, the contribution the amateur service could make to the microwave state of the art is nil. Finally, the people who might spend their time working on amateur microwave could make a very important name for amateur radio. They could make a name that would be heard and recognized where it matters.

The microwave frequencies are familiar and well-known territory to military and commercial communicators. The frequency congestion in some parts of the country makes the California two meter repeater problem look like the wide open spaces. Millions of people daily talk over long and short distances on 15 GHz and up without causing any excitement. Digitized transmission systems are becoming the rule and are replacing the old analog modulated networks. It is not in the best interest of a vibrant and progressive amateur radio service to try to duplicate the plumbing and hardware developed so well so long ago. The fourteenth inventor of the wheel probably got very little notice. There is nothing much for us in the microwave frequencies. There is not much utility, no new ground to be plowed, no records to be set, nothing but a lost wandering in a wasteland full of funny machine shop products.

Now that I have alienated everybody who even knows what a klystron is, here is where I propose we put our efforts. We must skip around everything that is too high for coax and keep going. Go up to the new communications ground where the future is full of real frontiers. Go up to where new developments and uses are waiting to bring riches to individuals and pride to amateur radio. Go up to light!

The use of light for communications is just passing out of its infancy. Its first real steps were recently taken when the Bell System began using a light pipe to connect switching facilities in Chicago. Amateur use of light for communications can follow two very important parallel paths.

When amateurs think of using light for communications, they naturally think about transmission systems. This means shooting a light beam to some other guy and modulating it in some way. It does not necessarily mean relatively expensive lasers and high voltage power supplies. Light can be reflected, for instance. Sunlight for reflection is plentiful and free. The same hams who can design a moonbounce array can certainly figure out a cheap and easy way of modulating a reflected beam. Clouds might be a problem, but we have lived with the ionosphere all of these years, so what are a few clouds?

Light as a transmission system is certainly line of sight (unless you bounce it, that is). There are probably more and better ways to bounce a light beam than a microwave beam. They just need to be developed. Instead of a repeater on a mountaintop, how about a mirror? Want to talk to somebody? Just kerchunk the mirror. Not as good as two meters for mobile, probably, but a whole lot better than 10 GHz. On field day you could rent one of those searchlights they use at shopping center openings! Moonbounce is still a good bet, too. During the day your moonbounce reflector could probably provide hot water for your house. (Please don't write to me and tell me you can't reflect light off the moon. I'll have a whole generation of song writers ready to pounce on you.)

Along with light as a transmission system, there is another path that amateurs can explore which will be far in advance of available commercial systems. Light can be filtered, chopped, amplified, heterodyned, attenuated, modulated, and detected (and just about anything else that can be done to rf). It is not, however, inherently leaky. When contained in a glass or plastic light pipe, it is immune to electromagnetic hum, crosstalk, rf feedback, etc. Light pipes can be driven by our everyday friend, the LED. Light can be used, then, at lower level stages instead of af or rf to generate and process signals that can use rf, af, or light as a transmission system at higher stages. What I'm suggesting is that your Sooper Blinker 20 meter SSB rig of 1982 might very well use light starting right at the microphone to generate and process the audio that would eventually modulate the 14 MHz rf stage. Why? Because sand (glass) is cheaper than copper ore. Light needs less shielding and is less troubled by ground loops, etc. All sorts of neat processing can be done with the spectrum available.

This means that amateurs who don't want to use light as a transmission system can still experiment with and develop very important techniques in their own shacks. This activity is very much in keeping with the historic experimental tradition of amateur radio. The size and cost are low, and the potential is enormous.

I call on the gadget lovers and tinkerers in amateur radio to get with it. Quit trying to interface your SSTV to your microprocessor, let microwaves cook baked potatoes, and move up to light. *73 Magazine* has led the way in slow scan, 2 meter FM, and microcomputers. It is now time to start sending in articles on the newest and grandest development yet. Do you see the light?

Capt. Frank J. Derfler K9KIC
APO San Francisco

HRO

In 1978, hams all over the world will witness an event that will bring them undreamed-of fame – The Ham Radio Olympics. The HRO will accomplish what years of public relations could not, making ham radio a respected household word throughout the world, in Africa as well as in California.

Since 1979 will be the decisive year for ham radio, in the World Administrative Radio Conference (WARC) which will meet to decide what frequencies ham will use, the HRO will come at just the right time. The good press the HRO will obtain, and the national prestige it will engender, will carry over into the WARC and we will see countries competing with each other to get the best deal for ham radio.

Later this year, the International Amateur Radio Union will proclaim 1978 the year of the HRO and will notify all the governments which it represents. A committee will meet in Geneva to make simple preparations. What the committee will have to work out is what kind of events will not favor large countries and power amplifiers. There will be events of skill, perhaps tests of code reception and transmission, total number of contacts, longest distance per Watt on each band, or the ability to work through a satellite.

After the week or so of competition, the committee will convene, report on what they heard, and vote. They will present awards to the winning hams and their countries.

It will take a lot of work and much organizing, but we can do it. 1978 will be a year for all hams to remember, the year of the Ham Radio Olympics, the year ham radio became the "in" thing, the year governments started favoring ham radio, the year before the WARC when hams came out with far more than even the ARRL dreamed of asking for.

East Hartford CT

Ham Help

A few years ago I ran across a construction project in the library of a fellow ham. Now we cannot locate the project, but if my memory serves me correctly, I think it may have been in one of your publications. I would appreciate your help in locating it.

The project was a solid state device to track thunderstorms. This is the solid state version of an original article, "An Electronic Storm Finder," which first appeared in "The Amateur Scientist" column in *Scientific American*, May, 1963, p. 167.

I require a schematic diagram and alignment procedures for a Hallicrafters "Skyrider 23" receiver. The manufacturer says it's out of print. Many thanks.

J. Sutherland
P.O. Box 210
Hampton, N.B.
Canada E0G 1Z0

I am writing to try and find something about a new animal we are all beginning to know if not love: interfacing. I wish to develop a teletype system for my shack that is as noise-free as possible. I live in military quarters here in Germany and complaints about RFI are bad enough without having the neighbors complaining about the noise of TTY machines. I am also trying to keep the cost of the whole thing within a military salary type budget. This obviously knocks out HAL products.

I would like to develop the system around an AFSK type demod. This will prevent extensive modifications to the radio equipment. Now comes the interfacing problem. I have been faithfully reading all the I/O articles and the ham TTY articles, and hopefully have developed a vague reading knowledge of the medium. I have also seen that most of the different systems would be totally incompatible with each other. ASCII-to-Baudot/Baudot-to-ASCII converters look great to tie a computer to a TTY machine, but will they tie an ASCII encoded keyboard to a TTY demod? Will they tie the demod to an ASCII video character display?

What I would really like to know: Have you any suggestions for kits that would be compatible and not overly expensive? I'm not trying to force a manufacturer's recommendation from you. I realize that you have to maintain a fair outlook towards them all. I'm merely trying to keep from a lot of experimentation with some rather expensive devices that might not like one another at all. My working knowledge of digital circuitry is limited to the speed keyer and digital counter level. I haven't dived into LAI circuitry at all as of yet. I do see a computer in the future, but it is a financially far future.

If I haven't completely confused you by now, I hope you have something which will point me in the right direction. I will be QRV for any suggestions to keep the old TT-15 from keeping the neighbors awake.

Charles Dedon WA5WZI
Rt. 1A, Box 500
Walker LA 70785

Even though I am not (and cannot become) an amateur, due to disability in my hands, I do read your magazine. I teach electronics free to any young person who is really interested, enough to give up an hour or two a day. We use mostly surplus material to build projects, and have great difficulty in getting data on much of it.

Can anyone provide addresses or sources where we might obtain data on integrated circuits, nixie tubes, or related components? For instance, we have a 12 tube readout, alphanumeric, which we would like to use, but can find no information on.

The tubes are 13 pin (5 in front, 6 in back, a blue sleeved lead on each side). Monogram on back: ISE-DG12C-HB:D. ICs: DP4, DN2, HD3107DM, M5B201, M5B205, M5B207, and one M5B212, with associated transistors, diodes, and resistors, which we do have data on.

On the board are these numbers: HEC 011 EPA, 504-PCB-B, and 13925-H. Please send any information.

Montpelier OH 43543

RTTY Loop

This month we are going to discover just how Teletype is sent. For the purposes of this discussion, forget all you know about radio. During the next few minutes, the only way to get information from point A to point B is by stringing wires. You'll see why later. Now let's look into non-voice communication systems.

I am here, and you are there, and I want you to get me a hamburger. So I string a wire from me to you and connect a switch, battery, and bell. See Fig. 1. We agree that one ring means "hamburger," two means "7-Up," and three is for "french fries." What do we do for chicken soup? Clearly this system is limited, and some encoding form is needed. Obviously, that is what alphabetic codes, such as Samuel F. B. Morse's, do. But this type of system did not lend itself to automated systems in the PICE (pre-integrated circuit era). We need a way to send each letter and figure from me to you and have a machine interpret it.

Fig. 1.

Refer to Fig. 2. Twenty-six buttons, plus any figures or punctuation, are at my station. Each of these buttons (arrange them in a keyboard if it will make you happy) is connected to a long wire which spans the gap 'twixt you and me. At your end, each wire feeds an electromagnet with some linkages resembling an electric typewriter. I hit the "Q", the "Q" wire is energized, your "Q" magnet pulls in, and a "Q" is typed. Add some means of returning the carriage (CAR RET) and feeding paper (LINE FEED) and you have a workable system. (These two are also abbreviated CR and LF.)

But wait a minute. You have to string more than 30 wires who knows how far just to do this. If you will pardon a bit of borrowed terminology from the computer folks, this is a "parallel" system. That is, all wires (bits) are there (read) at the same time. All we have to do is convert this to a serial system and send each bit sequentially, and then we can go back to one wire between stations.

Take a glance at Fig. 3. Now we have added a motor-driven selector switch to each station. Now when you push a button, two things happen: The clutch engages and a "START" pulse is sent, and the appropriate letter pulse is sent at the correct time. At the other end, the "START" pulse engages the clutch, and, since the motors are turning at *exactly* the same speed, when the pulse for the letter sent arrives, the receiving selector switch will be at the appropriate

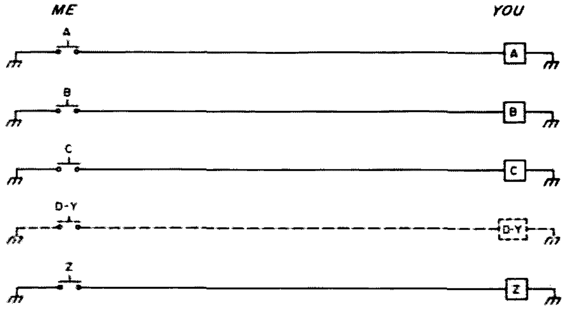

Fig. 2.

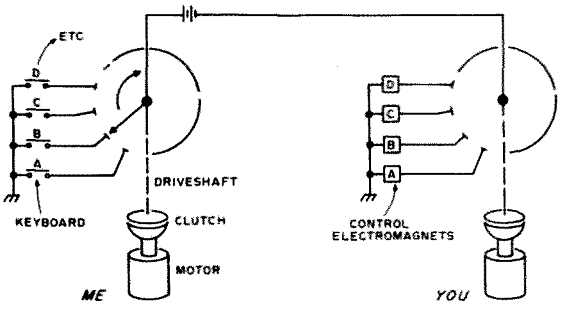

Fig. 3.

terminal to activate the corresponding magnet. Neat, huh?

Only one problem. Just to send the letters of the alphabet, you need 26 pulses plus the START and STOP pulses. Twenty-eight bits! At, let's say, 25 ms per bit, a reasonable speed, it would take almost ¾ of a second to send each letter. That works out to around fifteen words per minute. There has got to be a better way. There is . . .

Take five bits and encode them in a binary progression. This gives 2^5 or 32 possible characters. To get more, without using more bits, use both upper and lower case. Fig. 4 shows one possible scheme. Now, reduce the switching of Fig. 3 to send just five bits plus a start and stop, and you can send whatever you want, with 22 ms pulses, at 60 words per minute. Make the pulses shorter and you can send faster, and this really works!

To make it practical, when you push a key on the keyboard, mechanical linkages set up the appropriate five-bit code, which is then scanned by the motor-driven switch and sent down the line. A selector magnet driven off that line pulls levers in as a toothed wheel allows brief samples of each pulse interval. The received letter is sequentially encoded and, at the conclusion, read out in parallel form. Levers and trip hammers are set, and the proper key is struck on the platen. For the computer buffs out there, note that the characters are first generated in *parallel*, converted to *serial* for transmission, then received *serially*, and reconverted to *parallel*.

BINARY	LC	UC	BINARY	LC	UC	BINARY	LC	UC	BINARY	LC	UC
00000*	BL	BL	01000*	LF	LF	10000	E	3	11000	A	–

**Notes on individual codes:*

00000 – BLANK, cycles machine in open condition. Will shut down machine in some loops.
00010 – CARRIAGE RETURN, usually abbreviated CR or CAR RET, returns type basket to left hand margin.
00100 – SPACE, advances typing basket one space without printing.
00101 – H, in upper case may be £ (pounds sterling) or STOP. This, used as stop key in some circuits, has no radio use.
01000 – LINE FEED, usually abbreviated LF, advances one line of paper.
10100 – S, upper case usually BELL, which rings a loud bell in the machine. Some machines type ' instead, and use upper case J for BELL.
11010 – J, upper case ' (apostrophe). See note for 10100, above.
11011 – FIGURES, usually abbreviated FIGS, puts machine in upper case.
11111 – LETTERS, usually abbreviated LTRS, puts machine in lower case.

Fig. 4. Binary Teletype Code.

A common problem for RTTY operators involves the mechanical speed of Teletype equipment on each end of the "loop." Again referring to Fig. 3, it can be seen that the receiving machine must be in the "start" position when the transmitter sends a start pulse. Imagine for a moment what would happen if the two machines were not synchronized to each other! Most likely, an invalid "garbage" character would be printed, which is exactly what happens when RTTY is transmitted over a noisy path. Some method of insuring machine synchronization is required, and fortunately the problem is easy to solve. The power company maintains close watch over the frequency of our line current, and, while voltage may vary considerably, the frequency is always very close to 60 Hz. This fact is employed to our advantage in most TTY machines. The motors that drive the mechanical linkages in the machines are usually "synchronous" motors; that is, their speed is a function of power supply frequency, not voltage. Most synchronous motors will maintain speed over a wide voltage range, although their torque suffers at voltages much below 100. Thus, when the TTY machines at both ends of a path are driven by synchronous motors from the power line, they are automatically "in step" with each other. True, there are adjustments on all machines that can cause misprinting. These will be discussed at a later time. The moral of the story is to be sure that any surplus machine you purchase has a synchronous motor. This fact can be verified by checking the information plate on the motor. It should say "synchronous." Avoid machines with "shunt" or "series" motors. Usually they are not worth the effort, no matter how attractive the price. These machines are synchronized by mechanical governors and springs that are never accurate over the long term. Many military machines fall into this category, as they were designed for field ac/dc usage. Pass them up if anything else is available! Future columns will describe the equipment available for beginning RTTY applications.

Hopefully you are now aware of the "mechanics" of Teletype transmission and reception. The next step is to eliminate the wires between the transmitting and receiving stations. After all, the "R" in RTTY stands for radio. Next month's column will outline the encoding and transmission of TTY pulses over radio.

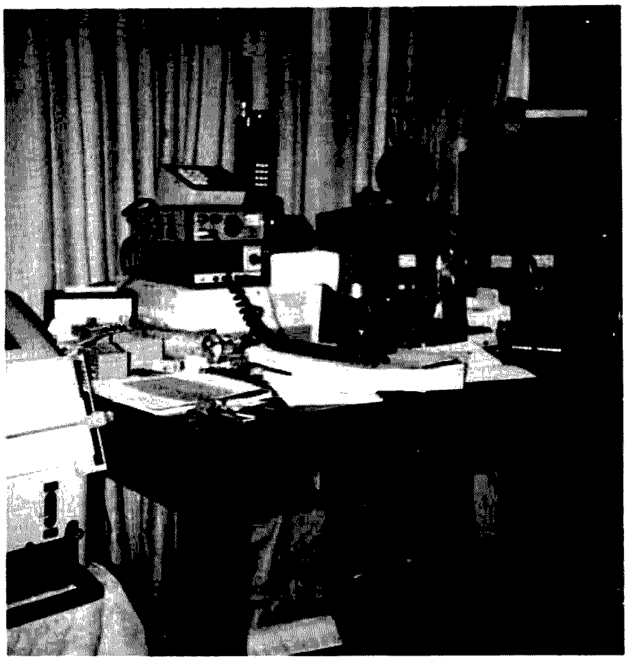
LINKING AMERICA

Just another normal Sunday evening on .01/.61 in Los Angeles. Let's see. There was myself, Mary WA6LUC, "Uncle" Earl WB6MUQ, Doug K4SWJ and Bill WB2RXQ, to name but a few. Why should this be of note? Well, you see, Doug and the rest of the "4 landers" were in Atlanta, and Bill RXQ and the rest of the "W2" stations were in Staten Island, New York (and we must not forget that fine group of "1's" on the WR1ABB system near Boston). Not exactly what one thinks of as your average "run of the mill" evening QSO on a local two meter system. In reality, though, it's not your average two meter anything.

What it was and continues to be is a project in repeater interlinking spearheaded by Sam Davis WA1GQY/WB6GDM. Not long ago, Sam placed into operation what he calls his "magic talking box," better known as the WR6AYY 220 repeater/remote system. He got the idea that there was more that could be done with it than just talk locally. Heck, why not link it to another machine in another part of the country and let the people in both places rap with one another for a while? Since Doug had been a popular resident member of the L.A. repeater fraternity when he lived out here, the first choice was evident: a link to Atlanta. However, we thought that using AYY (a private 220 system with a dozen or so members) might not be as much fun as having access to this link from a major high traffic open machine. Since AYY was a remote base as well as a repeater, it would be easy to tie it to virtually any two meter system. That's how WR6AUD (WR6ABB) got involved.

At about 7:00 pm on Sunday, May 2, 1977, a group of W4's suddenly appeared on 146.61 in L.A. They could easily be talked to by transmitting on 146.01. Involved in the linkup were the aforementioned WR6AYY, WR6AUD and WR1ABB, as well as WR4AAE (Atlanta) and WR2ADP (New York). I only wish there were room to list everyone who took part, but space restrictions force me to limit kudos to Bill Helfand WA6JEU of PARC (for his technological wizardry), Mary Stocksdale WA6LUC (who spent about four hours as "emcee" here in Los Angeles, keeping the whole show moving along), and Sam Davis WA1GQY. Sam's "let's do it" attitude had the effect of uniting an entire continent via amateur FM relay com-

The WR6AYY "Magic Talking Box," with its creator, Sam Davis WA1GQY/WB6GDM. Photo by Norm Smith WB6DGF.



Linking America's "control central," at the home of Sam Davis WA1GQY/ WB6GDM. Photo by Norm Smith WB6DGF.

munication, with a slight help and a large phone bill from Ma Bell. When I asked Sam why he did it, he simply answered, "It was fun."

If you happen to have such a system, that "wants to get involved" and also happens to have autopatch facilities, you might drop a line to Linking America, c/o Sam Davis WA1GQY/WB6GDM, PO Box 1502, Sun Valley CA 91352. Who knows? If you do, one of these Sunday evenings we might get a chance to QSO as well.

REPEATER APPRECIATION WEEK

After the storm: Contrary to what you may have read elsewhere, the event previously described in this column in detail has had a profound and lasting effect on overall repeater operation in this area. Now that enough time has passed to really evaluate it, I have to reach the conclusion that the prime reason for its overwhelming success is that none of us, myself included, ever wants to have to live through another such repeaterless time.

In the basin, the day of the repeater hog and abuser is waning. It is giving way slowly but steadily to the day of the good guy, the average "Joe Ham" who was for a long while the target of the abusive minority that had almost made "repeater life" untenable. Repeater Appreciation Week changed all this, however. It made old "Joe" aware of the fact that if the privilege granted him by his peers was to continue, then he would have to take on the most important burdens of all — setting the best possible example for the rest of the amateur community, and being his own "repeater cop" when necessary.

To cite one example, six months ago it was quite common to hear a bunch of people rattling off about some unknown poor "flake" who had gotten his jollies by jamming or harassing a given system. Nowadays, about the only time you hear such a complaint is at off-the-air meetings. Not that all the on-the-air jammer recognition has abated, but the unofficial word seems to have proliferated enough that most people know these days that if you want to really frustrate a jammer, foul mouth or sickie, the best way to accomplish this is to totally ignore his existence. I'm willing to bet that there is more complaining going on on the telephone on this topic these days than on the air.

In the years I have been writing Looking West, no topic has brought the mail load that this one has. In fact, some has come from as far away as Germany, which at least lets me know that this column gets read. In general, responses from densely populated areas were positive on the action taken by the "Ad Hoc Committee for Open Repeater Appreciation," while those from less populous parts of the country went as far as to say (in certain instances) that the overall deterioration level we had described could not possibly have existed. Some said that no matter how bad things had become, no one had the "right" to take away the repeaters. A few went so far as to say that, whether supported or not, the repeaters belonged to the people who used them. Therefore, they reasoned, the licensees should be prepared to take anything that comes. Most, however, cited the whole affair as being not only a shame to have happen in the first place, but also a "blot" on the overall face of the amateur service. Having personally lived through the period of decay, the action itself, and the subsequent revitalization now going on, I could not agree more with this last view.

Another interesting point is that, with few exceptions, those responding negatively gave little or nothing in the way of counterproposals that could have been attempted before any such drastic action was taken. Most negative comments were just that — negative on the basis of "right to operate," or to the effect that "something else" should have been done. Never could we figure out what this elusive "something else" was, however. Many letters claimed that I had not been objective enough in my reporting on this topic and had given too much column space to the "positive results" (while downplaying the negative aspects). To this I can only say that we judged by what we heard on the air, and never once did a confirmed, "self-professed" bad guy, "repeater hog," or "jammer" call us on the phone to complain.

I had hoped to be able to reproduce a few of the comments and responses received. However, due to space limitations and the desire to avoid repetition of things already discussed, I think it best to put this one to rest with the following summary. For us, the concept of "Repeater Appreciation Week" did work. It did have what has turned out to be a long-lasting positive effect. It did lead to "cleaner" overall area operation in general, although we are still far from being the "world's showplace." If we ever were able to achieve the status of "showplace," I suspect that it would probably make for a rather lifeless, sterile, and uninteresting format of operation. While such might be welcomed by some, to the vast majority of local amateurs a totally sterile atmosphere would in itself create another form of decay: attrition of both amateur relay communication and the numbers in our ranks. We can afford to lose the bad guys, the troublemakers, foul mouths and the like, but losing the good people, those who appreciate what others have done for them and show that appreciation through due respect for their fellow men, we cannot tolerate.

In essence, we are again climbing the ladder. We are looking for a happy medium some place in between, a place that fits and suits the lifestyle that is Southern California. This time we are aware of the pitfalls that mistakes lead to. I suspect that this awareness is the insight we need to reach the "happy medium" we are striving to attain. If we fall along the way, we will only have ourselves to blame.

To those who have asked if I recommend action such as this to others, I respond by placing the responsibility for finding this answer back on their shoulders. Because it worked for us does not mean that it is the ultimate answer to all the problems plaguing open repeaters everywhere. You alone can judge the degree of the problems in your area. You alone can determine if all other avenues have been attempted to correct these problems and if taking drastic action, such as holding a "Repeater Appreciation Week" in your area, will solve anything. It is not a solution in itself but only another tool in attaining a one. I sincerely hope that you never find yourselves having to implement such drastic action as was seen here in January. Be wary; the fact that it helped us does not guarantee that it will work for you. Use your own individual and collective judgments.

THE WAY UP NORTH: THE CENTRAL VALLEY IS ALIVE, WELL AND ON TWO METERS

Another subject that has brought a heck of a lot of mail, mostly from the Central Valley area of California, was part one of my November '76 trip to Northern California and the San Francisco area. It seems that I may have hurt a lot of people's feelings in the Central Valley by not mentioning the activity I found there. To those I may have offended, I apologize; to those that were kind enough to write me with updated activity information, I say thank you; to those who spent many paragraphs berating my ownership and use of a CB radio, I have nothing to say whatsoever. Correction: To the latter group I suggest that energies could be better spent in more constructive ways than tirades against CB. Sure, it has its problems, and true, it's not "ham radio" type communications, and yes, there can indeed be a language barrier. I have come to the conclusion that in a crowded urban area such as L.A., the lower 23 are usually so crowded as to be useless, with the possible exception of channel 9. However, once out of a city like L.A. (with its massive numbers of spectrum users) and "on the road," you won't find me making any long trip without one. Enough on this, though: Let's get into the activity we found heading north on I-5, and fill in the material supplied on what we missed heading south on 101.

After running out of the range of the Los Angeles area systems our Denshi radio was crystalled for, our first interesting encounter came on that popular channel pair of .28/.88. Thanks to Ken WA6TCP, we were provided with the following information about WR6AIF (and a rather enjoyable 25 minute QSO, as well). WR6AIF is a wide coverage open system located atop a 5700' "bump" known as Blue Ridge, which, for those of you trying to pinpoint these things on a topographic map, is about 22 miles east of the city of Visalia. The system runs about 40 Watts erp, is open carrier squelch access, and is owned and sponsored by the Tulare County Amateur Radio Club, Inc. One of the nicest things about it was the totally relaxed atmosphere we found.

The timeout timer is approximately two minutes and forty-five seconds, so it is quite easy to compose your thoughts as you proceed with a QSO. Ken says that while it's usually a fairly quiet daytime operation, weekends, holidays and evenings the system really comes alive and a QSO is not hard to come by. In our case, we were weekday travelers, but found no problem finding a friendly hello on WR6AIF. If you are in the area and

see a sign marked Exeter or Visalia, you might give a call on .28/.88. I suspect that the ensuing QSO will be one you will enjoy.

A little farther up I-5, just past junction 44, we found ourselves in QSO with Dick W6OV via the WR6ACU repeater located at about the 4000' level at Meadow Lakes. ACU is, according to the latest NARC listings, one of three open .34/.94 repeaters in their jurisdictional coordination area (along with three others which are tone access). Meadow Lakes is located just north-east of Fresno, and is the kind of vantage point that gives ACU good coverage over most of the Central Valley, from an area just north of Bakersfield to the intersection of Route 580. That, friends, is what we call coverage. While I did not have .31/.91 in my radio, Dick informed us that WR6ACE (located atop McKittrick) had similar wide coverage characteristics. Again, the kind of welcome we found on ACU was outstanding, and causes me to wonder a bit about stories we hear from time to time about a traveler in a given area "getting run off a repeater" because he did not belong to the "in crowd." We were strangers on a heck of a lot of systems on our trip, and never once were we made to feel unwelcome anywhere. If these things do happen, it's surely not in the Central Valley or San Francisco area.

Once north of ACU's area of service, we began the normal ritual of running through our 10 repeater pairs. As we came to .01/.61, we found ourselves eavesdropping on a rather interesting QSO on the WR6AFA repeater. I like a good technical discussion, so after a few minutes we made our presence known. We soon found ourselves in QSO with AFA's owner, Steve WA6SBM. We never did ask Steve where AFA was located. However, we accessed it about the time we ran out of ACU, and were with it for about an hour (until Steve informed us that we might be at a point where we could gain acquisition of WR6ACV near Stockton).

It turns out that Steve is one of the "new pioneers" of VHF up there. He already has in the works a 220 system (that will be on the "low .34/.94" pair), a UHF system, and a six meter system (that he plans to link to another six meter system running in the Marin area). He plans a few autopatches in this web of rf as well. Steve was a veritable gold mine of information, and since our QSO took place about five months ago, a lot of what he described to me as being a part of the future may have already come to pass. A word of thanks to Ray WB6GUK, who sort of got placed on the sidelines as Steve and I rambled on. One of these days I've got to make this trip again, if for no other reason than to see how much of Steve's major undertaking has been accomplished to date. I found myself that fascinated.

I wanted to get hold of my buddy Dave WB6IRL who lives in the Stockton area. That part of the world is serviced quite well from the .28/.88 WR6ACV repeater atop Mt. Oso. Dave and I first met at a training session here in L.A. being given by the company we both worked for at that time. At any rate, after finding that we could work into Mt. Oso, we gave Dave a call and were surprised to get a response from his XYL (who we did not know had obtained her ticket). We were informed that Dave was out at the moment, and that as soon as he returned he would be summoned to the magic talking radio. A while later, just as we were leaving ACV's service area, we did manage a few minutes with Dave (which were continued the following evening via landline).

I-5 sort of skirts the prime coverage area of WR6ACV. However, with nominal power and a good receiver it is possible to work this system over a good number of miles. In most places, our 12 Watts and 5/8 wave GAM were more than sufficient. ACV is a system-designed repeater, in that it is one where if you can hear it, you can work it. Conversely, if the road takes a dip and you go away for a few minutes, you won't hear it either. In practice, this is considered proper overall system design, and is exactly what those involved in commercial land mobile service strive to attain. We finally lost ACV altogether as we started the "big climb up the hill" that leads down into the "City by the Bay." In the interim, however, we had a chance to chat with Dave, Joyce, and a large number of other super people who make WR6ACV their home.

Since we have already covered much of the activity we found in the Bay area in a previous column, let's say a quick farewell to the Golden Gate and start south via Highway 101. Heading south in the rain, we found a rather interesting QSO on WR6ABM. As we found out from our QSO, ABM is an open wide coverage repeater located in the Oakland area, designed to serve both the San Francisco Bay area and the Sacramento Valley. From what we noted, ABM fulfills its task quite well; we found ourselves able to access it for almost two solid hours. As usual, those we met on the air were warm, friendly, and always eager to give us any information we found ourselves in need of. When questions were asked about the system, there was always a sense of pride obvious in the response.

ABM seemed to be the home of the two meter SSB enthusiasts. Those whom I QSOed with were quite interested in finding out about SSB activity in the L.A. area (the number of people using that mode, the times they operated, and the most popular calling frequencies). We tried our best to supply the requested information, and I can only hope that a few good QSOs occurred consequently. It seems that SSB is going like wildfire up there, so if you are into that mode, you might give a listen down near the low end near 145 if you think you are within earshot of San Francisco (especially during that summer phenomenon known as VHF skip). Remember, for the past two summers running, Hawaii has been worked from L.A. on both FM and SSB. Why not San Francisco to who knows where? As you read this in July, the "season" is here, so if it's going to happen, it's probably now or never. Not that it be "E" or "F2" necessarily. Many of the most knowledgeable have come to the conclusion that the Hawaii to L.A. thing was ducting.

We were on .16/.76 and hunting for a place to eat when we became part of an existing QSO on WR6ADE. Almost immediately, a very warm welcome came our way from Dave WB6KHP, who informed us that ADE was located on Mt. Chual in the Santa Cruz Mountains, approximately halfway between San Jose and Santa Cruz. There is a definite order of responsibility among those who operate ADE. For the repeater to be operational, there must be a control station present. ADE has two control levels (as explained to me). At all times, a primary control station is monitoring the system (as Dave said, there are usually three or four). There is also a secondary level of control, and a secondary level control operator must be present and obvious or the system reverts away from open access. Therefore, as I understand it, ADE operates as an open system when both levels of control and responsibility are present, and as a limited access system at other times.

Hospitality on ADE? During the QSO I had with Dick, Ian, and the rest of the ADE people, a fellow Angelino, Jesse W6BFO, came on channel needing a phone call to the San Jose area. Ian had to leave, so Dave took secondary control and waited for Jesse to reach a point where he was solid into ADE. Then, using the ADE autopatch facility, Dave handled Jesse's traffic. Sitting back and listening to the patch, I was reminded again of what our hobby/service is really all about. While it was noted that the ADE autopatch is normally limited to use by their group, it is my opinion that their willingness to share with an outsider is really a positive statement for a rather fine group of fellow amateurs. We had reached a restaurant by the time the patch was completed, so we said our "73s" to both Dave and Jesse. Dave reverted the system to primary control, and Sharon and I went to lunch. At least I thought that's what had happened.

Some twenty minutes later, when we again took to the road, we found that WR6ADE was still up and that Jesse was in QSO with Al W6MEO. Heavens . . . was all of L.A. up here this evening? As I found out, as I left for lunch, Al, who had been up north, was en route back to L.A. about 15 minutes or so ahead of me. Another secondary control station had taken over, in order to enable Jesse and Al to continue their QSO. That's just another touch of the hospitality afforded by the WR6ADE group. Soon, however, as we drove south near Soledad, we found ourselves leaving the service area of WR6ADE.

From that point until we reached the area of San Luis Obispo, our 12 Watts and 12 channels proved futile, except for a few quick .94 simplex QSOs with fellow transients. We did finally manage to get in touch with Al, who by now was about a half hour in the lead, and decided that dinner was in order. We met at a Denny's along the road and took an hour's break from the concrete and asphalt to renew an old friendship.

According to some of the letters we received, we should have been able to be in almost constant repeater contact. However, such was not the case. To this day I can't tell you why. The following letter from Ernie WB6HJW, very indicative of some of the mail that part one of this story brought, is probably the most up-to-date info available on activity in that area.

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

Dear Bill:

Just a short letter to let you know that amateur radio is alive and well in the Santa Maria area, despite what you indicate in your April column.

In Santa Maria we have a repeater (WR6AHZ, on 147.81/.21) which has been in operation since 1974. WR6ASW, 146.34/.94, is now located on a hilltop south of Santa Maria, although I believe it was at ground level when you made your trek north. WR6AEL, 146.22/.82, is located on Cuesta Grade (north of San Luis Obispo) and covers from Camp Roberts to Buellton. WR6ADS, 146.16/.76, is on the campus at Cal Poly (San Luis Obispo). WR6AVI, 147.72/.12, is on Harris Grade, near Lompoc, covers from San Luis Obispo to south of Buellton, and has been on since 1973 (formerly as WR6AEB). WR6AFI, 147.60/.00, is on Broadcast Peak above Santa Barbara, and covers from Paso Robles to the Mexican border (of course, not solidly).

WR6AHZ has autopatch into Nipomo, Arroyo Grande, Grover City, Pismo Beach, San Luis Obispo, Avila Beach, Baywood Park, and Los Osos. WR6ASW has autopatch into Santa Maria, Guadalupe, Nipomo, and Los Alamos. WR6AVI has autopatch into Lompoc and Vandenberg Air Force Base.

There are other repeaters in the Santa Barbara area (on 146.31/.91 and 146.19/.79) which are accessible south of Gaviota.

All repeaters in San Luis Obispo and Santa Barbara counties are open, and persons passing through the area are welcome to use them. Repeater use is monitored by control stations, but I have never heard any control operator interfere with any amateur's lawful use of a repeater. Most area repeaters are on 24 hours a day.

I hope on your next trip north (maybe for the Southwestern Division ARRL Convention to be held in Santa Maria, Oct. 7-8-9) that you find this area more hospitable on two meters and that you won't have to resort to CB to talk to someone. With almost 200 amateurs in the area on two meters, the repeaters are jumping.

Ernie Kapphahn WB6HJW
Santa Maria CA

We wish to express our gratitude to

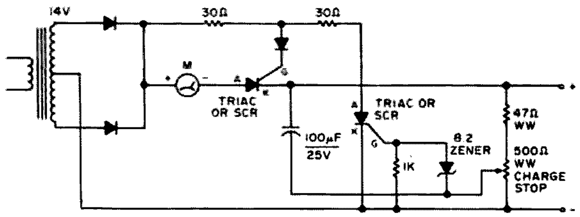
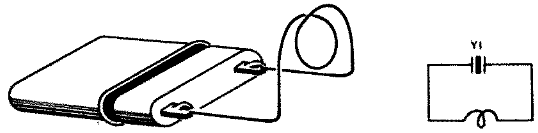
Circuits²

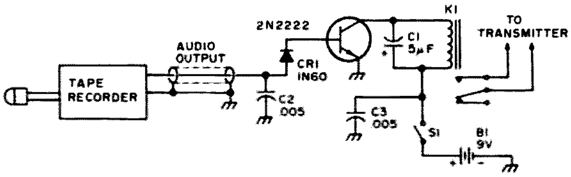
Want a free copy of any 73 publication? Sure you do. Just send in your favorite circuit, or even one that you don't especially like. If we print it, you take home the book of your choice. Just be sure to specify which book you want. OK?



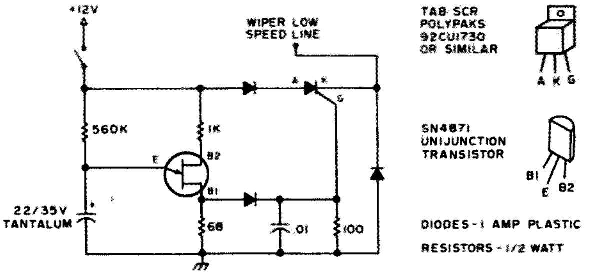
An automatic shutoff battery charger which will not dry out batteries. Must be adjusted by setting 500 Ohm resistor while attached to a fully charged battery. Thanks to W6ZNX.



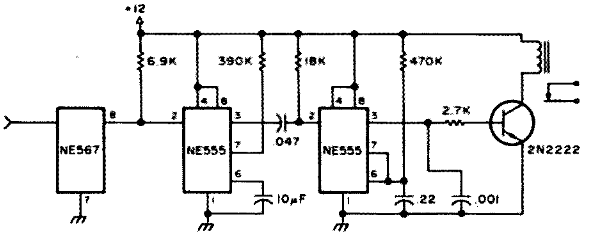
The simplest circuit yet for checking crystals. Attach a one-turn coil to a crystal socket and plug in the crystal. A grid dip meter coupled to this turn will dip at the resonant frequency. Thanks to W5QFH.



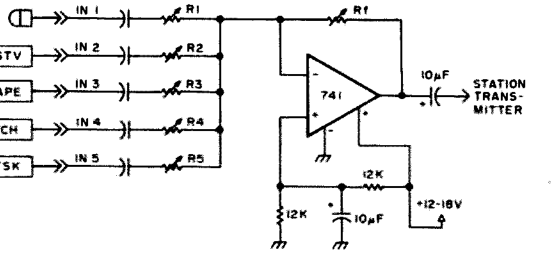
The tightwad special keyer memory for contest types needing memory for CQs and so on, but unwilling to assemble the conventional type. Construction and operation are simple, but be sure to keep stray rf out of the system through shielding. An audio oscillator is keyed into the microphone of the recorder and put on tape. Then the recorder is rewound and played into the circuit. Sensitivity is adjusted at the output of the recorder. Thanks to WB8TSY.



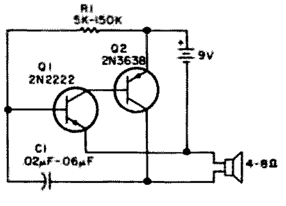
A good way to set your windshield wipers on an interval circuit. Only two connections to the car's wiper control, plus ground, are required. Variable control can be accomplished by substituting a 500k pot in series with a 100k fixed resistor in place of the 560k. Thanks to VE3OE.



This circuit was designed to give about eight seconds worth of delay after a reset tone is applied to the control receiver of a remote base. A tone can be applied for 1 or 2 seconds without appearing on the transmitter output. Thanks to W7CJB.

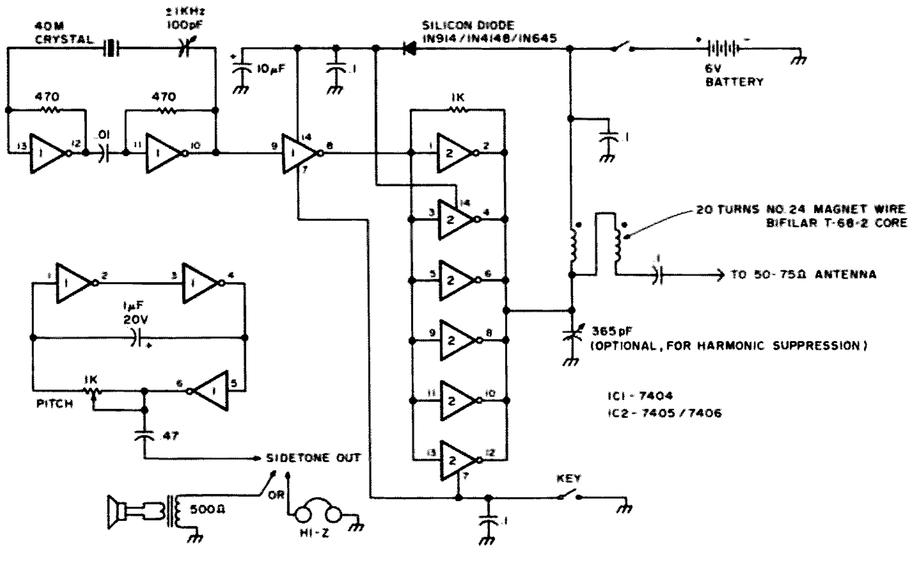


Here's a good way to input several audio sources to your station transmitter. It's an op amp in the "summing amplifier" mode. Overall gain is set by Rf while individual inputs are adjusted by their respective controls. Thanks to K7HKL.

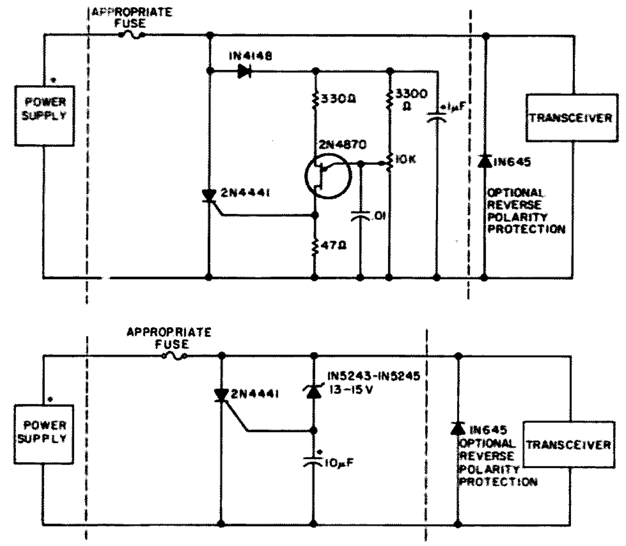


A good audio oscillator circuit. Almost any transistors will work, while R1 and C1 will vary the tone. The circuit has been used to find the correct pins on unknown transistors and as a simple test for good or bad. Thanks to M. S. Reid WA3JEF.

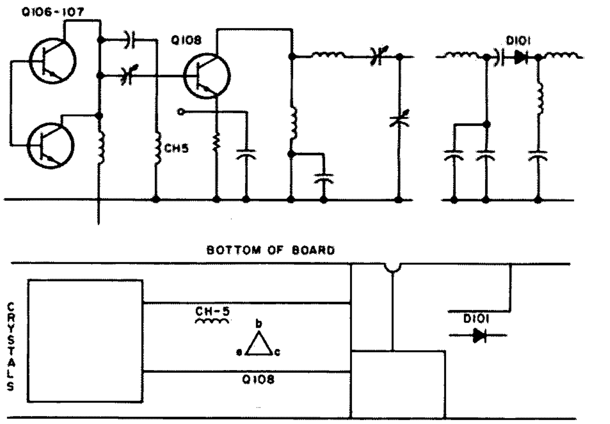
News? We need input, and one of the best sources is the club newsletter. Got one? We reiterate our longstanding offer of a free subscription to 73 or Kilobaud in exchange for a spot on your ham or computer club newsletter mailing list. Deal?



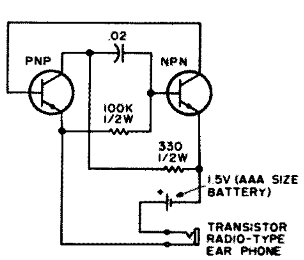
A super cheap 40m CW transmitter with sidetone monitor. Rf output is about 250 mW, and the cost should be under $5. Thanks to WB4CTC.



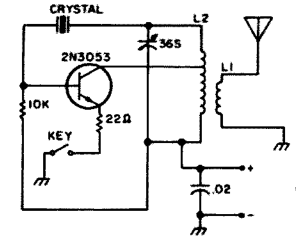
A way to avoid grief when using 12 V.power supplies with mobile transceivers. Most p.s. circuits leave room for a short circuit failure of the series pass transistor, which will do a job on your rig! Here are two crowbar circuits which will deliver protection by clamping the power line and blowing the fuse within microseconds of the beginning of an overvoltage condition. The idea here is to incorporate the crowbar directly into your transceiver, thus protecting the radio wherever you go with it. The chief difference between the two circuits is that the less complex of the two leaves you at the mercy of component tolerances for the exact trigger level, while the other includes a unijunction trigger to permit precise setting of the operating point. Thanks to W1DGD.



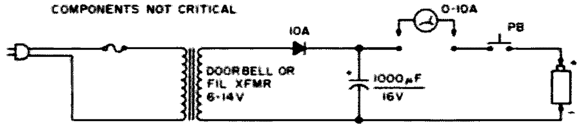
Wilson 1402 HT modification for those experiencing problems with diode D101. First replace choke 5 with a 100 Ohm resistor, then add a 25 pF capacitor from the base of Q108 to ground, and finally replace diode D101 with a jumper wire. Thanks to W8URX, through the LEARA Newsletter, *CA.*



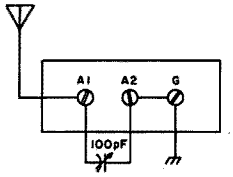
The simplest transistor checker yet! Choose a general purpose PNP/NPN and construct in a plastic box or small container. Color code the transistor and its socket. To check a suspect device: no tone, ng; low tone or chirp, so-so; steady tone, OK. A great circuit for matching transistors. Thanks to Bill Wentzel W3GWA.



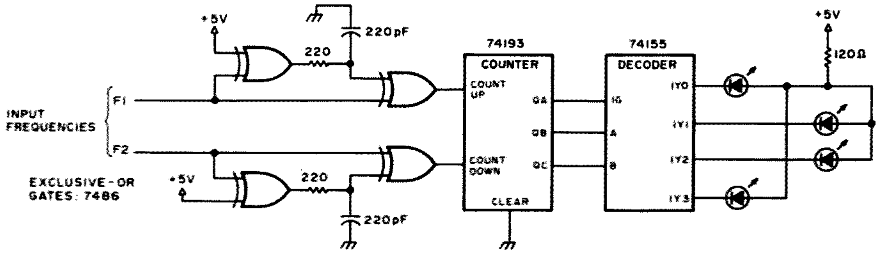
Another QRP transmitter, this time using a 2N3053 and fundamental crystals. Runs about 2 Watts output. Thanks to WB6OMV.



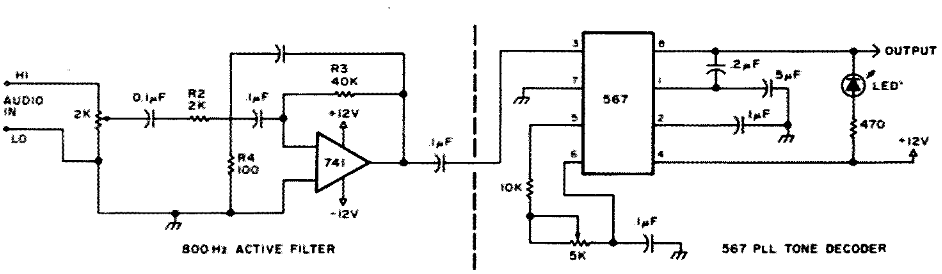
The nicad zapper used to restore dead or bum nicads. To operate, connect nicad to output and press button for 3 seconds. Thanks to K6JQD.



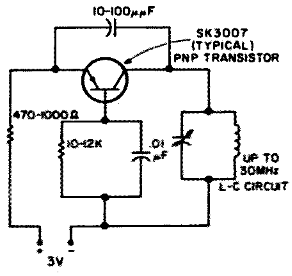
Many low-priced receivers for the 160-10m amateur bands do not have an antenna trimmer control. To peak up reception on your favorite band, mount a small variable capacitor (100 or 140 pF) at the antenna terminals on the rear of the receiver, as shown. Tune the capacitor for a maximum reading on the S-meter. For a more permanent arrangement, the capacitor may be mounted inside the receiver cabinet and tuned from the front panel by an extension shaft and knob. Thanks to W3WTO.



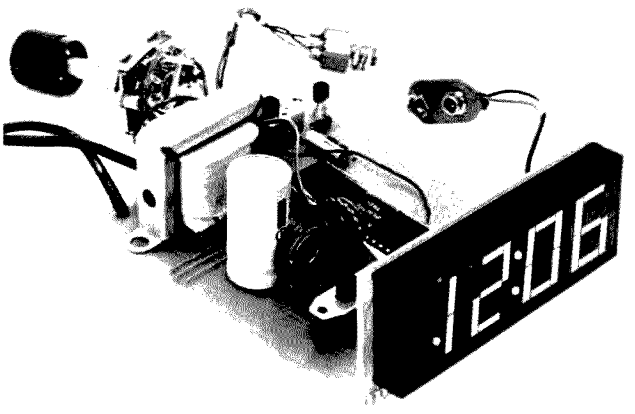
This circuit uses LEDs to display the beat frequency of two-tone oscillators. Only one LED is on at a time, and the apparent rotation of the dot is an exact indication of the beat frequency. When f1 is greater than f2, a dot of light rotates clockwise; when f1 is less than f2, the dot rotates counterclockwise; and when f1 equals f2, there is no rotation. Thanks to WB8TFN.



Here's a Morse code decoder for the handicapped. It will copy very weak signals due to the narrow bandpass of the active filter on the PLL input. This can be powered by two 9 volt transistor batteries. Thanks to WA5SWM/5.



An rf oscillator useful up to 30 MHz. An SK 3007 PNP transistor is recommended. Thanks to WA5RON.



The Fairchild 0100 clock/calendar Technology Kit™.

electronics Division of Fairchild Camera and Instrument Corporation.

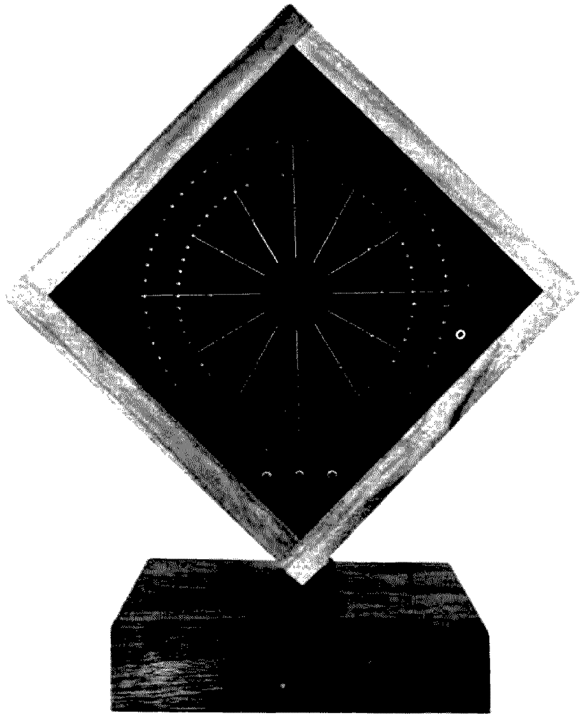
The 0100 alarm clock/calendar features an .8 inch, 3½ digit LED display with am/pm indicator. The clock, which displays time for eight seconds and date for two seconds, has connections for radio applications and may be connected to a nine volt battery.

The 0101 wall clock uses a 2½ inch, 6 digit LED display comprised of 175 LED lamps. The display, visible at up to 50 feet under normal conditions, alternates between time and date. If desired, constant time or date readout can be selected. The wall clock can also be connected to a radio with direct current for an external speaker, and contains programmable alarm features. *Fairchild Camera and Instrument Corporation, 4001 Miranda Ave., Palo Alto CA 94303.*

NEW AMELECT CLOCK

A new, revolutionary concept of displaying the time of day by means of the position of illuminated light emitting diodes (LEDs) in three concentric rings on a mirror-like acrylic face has been announced by Amelect, Inc.

These clocks, three years under development, are available in four styles and several kinds of solid hardwoods: walnut, mahogany, maple, cherry, and light and dark oak. The modern clock face is made of 1/8" acrylic with scribed markings to identify time positions. There are no moving parts, gears, motor, or hands. An outer ring of sixty lamps indicates seconds, and each successive illumination takes place at one second intervals. The middle ring of sixty lamps indicates minutes and changes each time the sixtieth second is illiminated. The inside ring of twelve lamps indicates hours and changes when the sixtieth minute lamp is illuminated. Actual time is shown by position of the three lamps that are illuminated at the given instant of reading. *Amelect Inc., P.O. Box 367, Goodland IN 47948.*



The Amelect CL 7401A with base.

NEW VHF ENGINEERING 30 AMP POWER SUPPLY

The PS-3012, a high current, 13.8 V regulated power supply originally designed for commercial two-way radio applications, is now being introduced into the amateur market by VHF Engineering of Binghamton NY. This power supply has been designed for demanding commercial applications through the use of a heavy duty transformer, dual heat sinks, and ruggedized case. The PS-3012 delivers 30 Amps at a 50% duty cycle, and 20 Amps at a continuous duty cycle.

The PS-3012 is available for $239.95 as a wired and tested unit from *VHF Engineering, 320 Water St., Binghamton NY 13902.* A rack mounted version is available as an option.

VIP-60 CONVERSION KIT

Valley Instrument Products of Bartlett IL has introduced a new programming device for the popular Icom 22S 2m transceiver. The VIP-60 conversion kit offers 56 preprogrammed frequencies, including all standard repeater channels, plus any four additional frequencies you choose. *Valley Instrument Products, P.O. Box 339, Bartlett IL 60103.*

Motorcycle Mobile

- - combining summer pastimes

The great outdoors. The clean air. You, riding off down the road, the wind in your face, on your trusty motorcycle heading off into the sunset. Ah, freedom! But the specter of a chain breaking, plugs fouling, or a tire going flat and you twenty miles from nowhere looms nearby. Anyway, riding around with all that freedom is lonely. There's no one to talk to. Even if you are with a group of people communication is limited to waving arms and sign language. There is a better way! Whether it be CB, HF, or two meter FM, motorcycle mobile is the answer to getting more fun from your bike.

First you have to decide what type of rig you are going to use. Unless your motorcycle has the battery and electrical system of a Harley-Davidson, you are limited to the many transistorized mobile or portable radios on the market.

The obvious answer is the handie-talkie. It's nice and small, very portable, has its own power supply, and is hand-held. Wait a minute! How are we going to go down the road using only one hand to operate the bike?

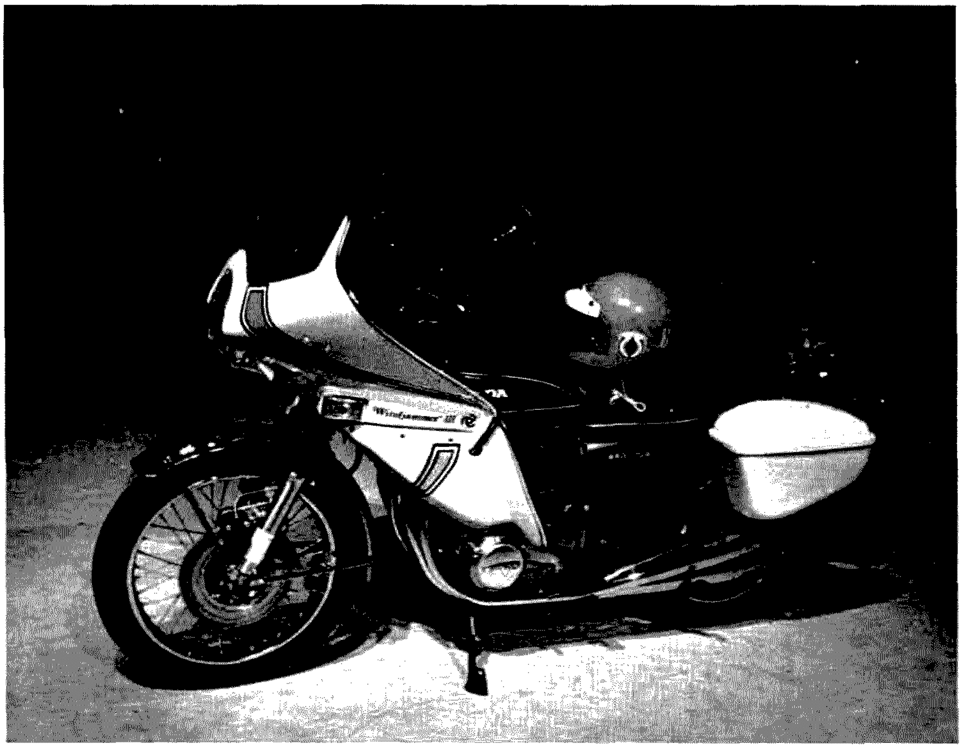
Well, maybe you could use a belt clip and some sort of external microphone/speaker combination like the law enforcement motormen use. This is OK if you don't mind your \$200-\$400 talkie flapping about on your hip, exposed to the elements (maybe bouncing down the road behind you?) plus the extra cash for buying the external microphone/speaker box. Anyway, how are you going to key the thing while under way? It looks like the obvious answer needs some rethinking.

OK, how about using that larger mobile rig? Well this, believe it or not, has got possibilities. The next question is, where am I going to put it?

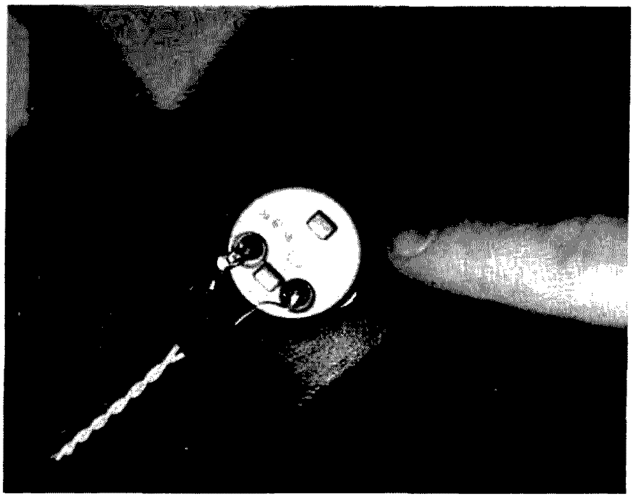
It has got to be handy, so some place up front would be nice. Putting the rig on the handle bars might work, but you would have to fabricate some sort of exotic mount for it, not to mention covering up the instruments (in the case of the speedometer, this would be costly) and adding extra mass to the front fork assembly which could be dangerous to the bike's handling characteristics.

A tank bag would work fine. This is a bag (approximately 12" x 8" x 8") of leather or vinyl material that straps on top of the gas tank. The bottom is padded so it won't scratch your paint job and the whole bag unbuckles in seconds so you can take it with you. It was designed for carrying one or two changes of clothes with you on a short trip. It is usually waterproof too. The cost is about \$40.

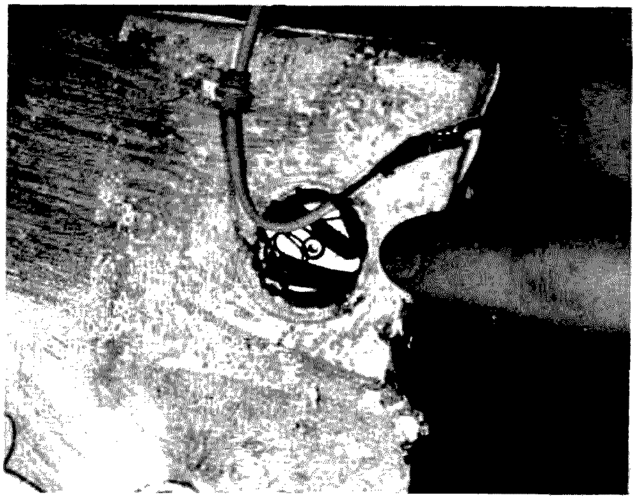
The best alternative is the space inside of a good frame-mount fairing. A fairing is a combination windshield/cowling protective device made from ABS plastic or fiberglass, which protects the rider and bike from the elements and road hazards. One week after I had bought a new 550 four cylinder Honda with a Windjammer fairing, a curb that was lurking in the dark jumped out in front of me. I broke the windshield in the resulting crash. The windshield had to be replaced, but the fairing, which was just a little



Motorcycle mobile — note connecting cord from helmet.



Rear view of front crash padding removed from helmet showing rear of microphone.



Styrofoam helmet liner showing earphone and cord detail.

bit scratched, had saved me and, more importantly, my new motorcycle from any damage. So at about $300 they are worth the money. Besides, the fairing has lots of storage space inside which is protected from the elements. Most mobile rigs will easily slide into one side of a fairing leaving still more room for extra microphones, headsets, and rain gear.

Now that we have the rig attached to the machine, how do we use it? First, we will have to make some sort of arrangement for a speaker. You may be able to use the rig's internal speaker if it's on the front or top of the rig and you are using a tank bag. If this is not the case, then an external speaker jack must be installed in the radio.

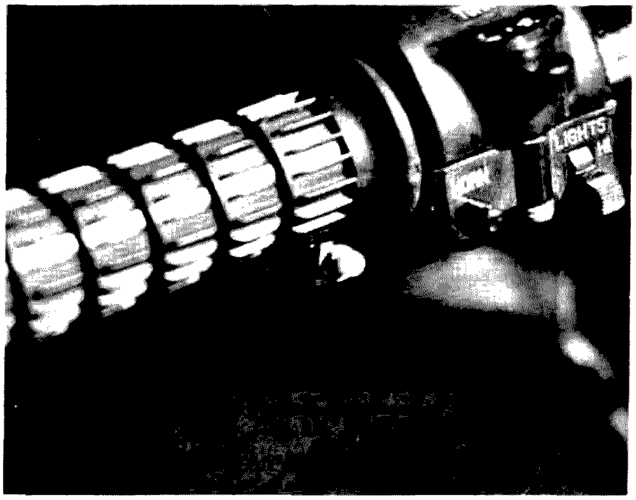
Now you have a couple of options: a speaker mounted on the handle bars, or an earphone/headset under your helmet. I went the speaker route first. It worked all right, but the rig has to be turned up so loud to override the sound of the motor, wind noise, and the natural attenuation of my helmet, that late at night I was in danger of being cited for disturbing the peace. Next, I tried a transistor radio earplug. This only had two problems: The audio quality was nonexistent, and I did not like the feeling of that "thing" in my ear. I then decided to modify my helmet. I will get into the helmet modification a little later.

After solving the speaker problem, the microphone problem is next. If you are using any helmet other than a full coverage type (one that comes down in front of your mouth and chin with a large slot for you to see out of), you can use a hand-held microphone with good success. Just drape it over the handle bars and (unless you want to use the clutch lever) pick it up, put it under your face shield and talk. The face shield really cuts down on the amount of wind noise that gets picked up by the microphone. Working the microphone close to your mouth helps, too. (You won't have any choice if the microphone is between you and the faceshield.) Using the hand-held microphone also eliminates the push-to-talk switch (PTT) problem that we are about to run into.

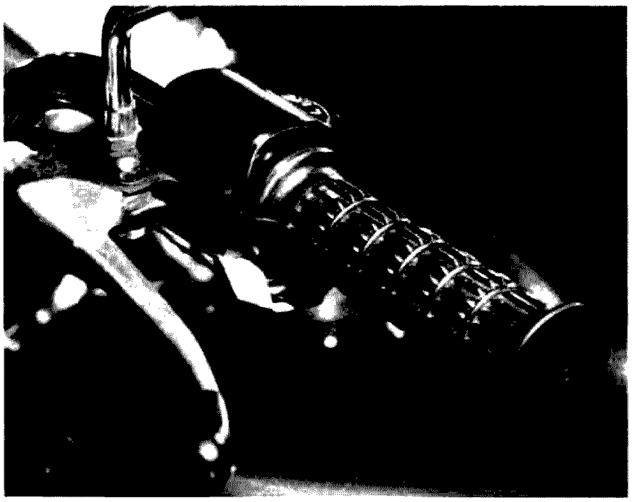
If we do not use the standard microphones, then we have a few problems: Where are we going to put the PTT, and how are we going to hang the microphone in front of our mouth for hands-off operation? Now we get into how to modify your helmet.

All good helmets have lots of crash padding inside. Usually it's styrofoam and foam rubber. The main protection over the head is the one half to one inch thick styrofoam. Foam rubber is sometimes used in front of the mouth in full coverage helmets and in a few other places such as around the ears. What most people don't know is that you can take the padding completely out of the fiberglass or plastic shell of the helmet. The padding is generally in two pieces, split from front to back down the middle. The crack may be covered up by a small decorative strip and/or a piece of foam rubber. Now comes the fun! You have to work one of the styrofoam halves out of the helmet shell. If you are careful and persistent, you will emerge victorious in this little bout with your helmet. The liner will be a bit stubborn, possibly because some of the cheaper helmets may use a little rubber cement to hold it inside the shell, but forge ahead! Remember, if it's a cheap helmet, they are too cheap to use a lot of glue on it.

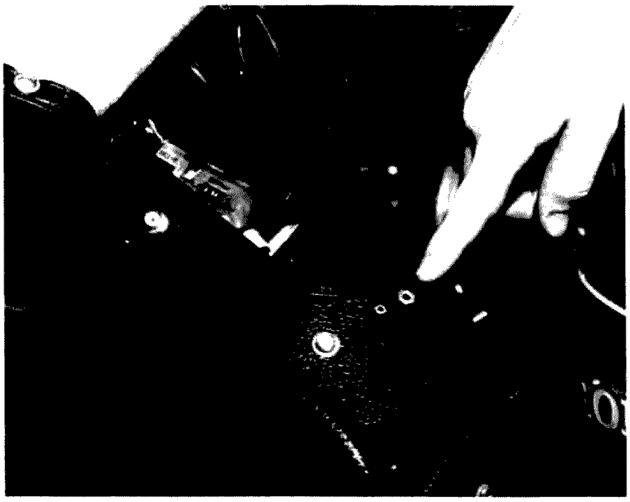
Once you get the first half out the other side will probably fall out. Now you can start the real modifying. I took an old headset that had a boom microphone on it and canabalized it. The earphone element was about 1.5 inches in diameter and about ½ inch thick. I then cut a hole in the styrofoam next to my ear and pushed the element into the hole. Since my element used a plastic membrane for its



PTT switch and bracket. Front view.



PTT switch and bracket. Rear view.

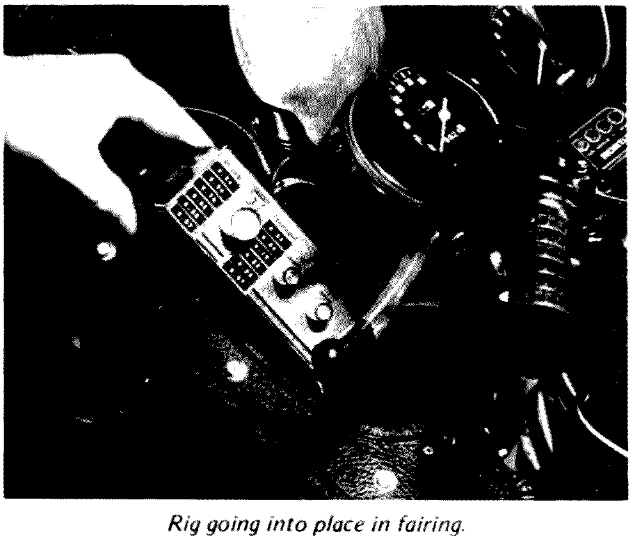


Helmet jacks mounted in fairing.

diaphragm, I put a hard plastic cover over it. The guard was a retaining cover from an old telephone type carbon microphone on a boom that telephone operators used to use. It just happened to fit over my earphone element. Anything that has holes in it that will prevent damage to the diaphragm can be used. I then ran the wires out the back of the liner. First, though, you can use a razor blade to cut a shallow trough in the styrofoam (the side that will contact the hard shell of the helmet) for the routing of the microphone and earpiece wires out of the helmet.

If you have a full coverage helmet, you can use the same procedure to mount a microphone element in the padding in the front of the helmet. For all other types of helmets you must make up some sort of microphone boom. The boom can be made with brass tubing from a hobby shop (approximately 1/8 inch diameter) bent into a smooth, gentle curve. The end of the boom where the wires come out can be epoxied into the styrofoam after a suitable trough has been notched out for it. Be careful about using glues on styrofoam. It may melt. Rubber cement may be better than epoxy.

Finding a suitable microphone element was the hardest part of the project. I had a small dynamic microphone element that came out of an old headset that I had salvaged the earphone and cord from, but the element was bad. After scrounging in many other people's junk boxes to no avail, I finally went to the local Radio Shack. There I found brand new replacement CB microphones (dynamic and ceramic) for only $8, which was about $3 to $4 cheaper than the replacement element I could get for my Sure microphone. Also, the element in the microphone from Radio Shack was only about ¾ of an inch in diameter. This would fit very nicely into the crash padding in the front of my helmet.



Rig going into place in fairing.

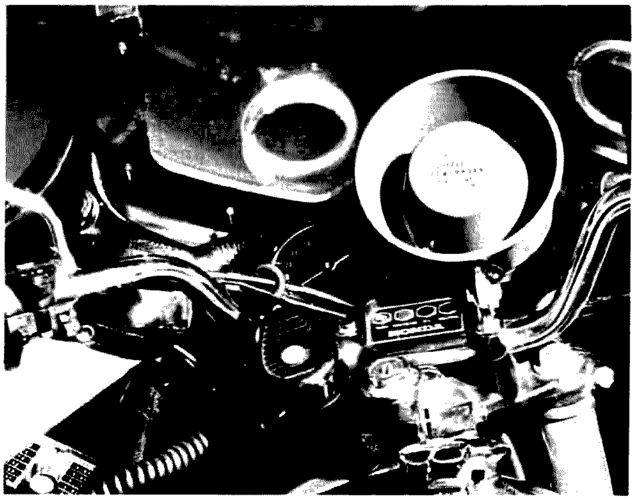
After you get all the elements in place in the crash padding, use some duct tape to keep it all from falling out before you get the liner back inside the helmet. Now all that's left is to put a jack in the fairing for the helmet to plug into and, oh yes, the PTT switch.

I tried two methods for PTT. The first is usable but is almost like using a hand-held microphone. I epoxied a small push-button normally open switch (five for $2 at Radio Shack) into an inverted cover that screws over a ¼ inch phone jack, and ran the wires out the smaller opening in the opposite end. I would then attempt to grab this assembly while motoring around town. I never realized that it was so small. After about two weeks of attempted use with this PTT, I found the better way. I built a small bracket out of aluminum and mounted the switch and bracket to a handy screw in the left-hand grip assembly on the handle bars. The switch is conveniently located right next to the horn button and can be easily actuated by the thumb on my left hand.

The last two items are the easiest. We have to have power for the rig, and we need a place for the antenna. If your motorcycle has a twelve volt battery, you have it made. Just run two wires from the battery to the rig. I would suggest running two wires rather than relying on the frame ground for your dc return. This keeps things nice and direct and avoids any intermittent ground problems cropping up later. Also check to make sure that your motorcycle electrical system ground is the same polarity as your rig. Motorcycles are not all standard twelve volt negative ground systems, and if this is different from your rig, you may pick up problems through the coax braid which will be grounded to the motorcycle chassis at the antenna mount.

The antenna mount I used was nothing more than some aluminum stock drilled and bent to mount on the rear fender attached to the rear tail light assembly. An

Antenna mounting bracket detail.



First try at going mobile — external speaker and hand-held microphone.

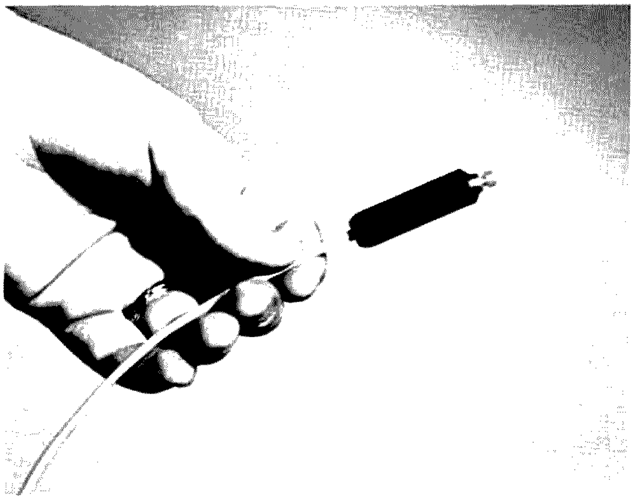
SO-239 chassis connector was mounted in the bracket. This way I can use either the traditional 1/4 wave whip in a PL-259 or the home brew 5/8 wave antenna which also ends in the same type connector. (See *73 Magazine*, "5/8 Wave Power for your HT," May, 1976, page 118.) If you then want to park the bike and not advertise the fact that you have a radio on board the antenna is easily removed. The battery wires and antenna coax are easily routed under the seat and gas tank and brought out from under the tank at some convenient spot. If you want to you can use tape or plastic cable ties to hold the wires in place as they go along the frame members. This will keep the wires off the hot engine and also keep them from getting pinched under the rubber supports of the seat and tank.

Now that you are ready to ride off in a cloud of dust, let me add a few words about operation of radios and motorcycle electrical systems. Most motorcycle electrical systems are marginal in capacity. You may find that you may have to be less long-winded than normal when operating motorcycle mobile to keep from running the battery down, depending, of course, on how much current your rig draws. I am currently using an HR 2 and have not had any problems keeping the battery charged due to the radio. However, my quartz headlight and extra marker lights in the fairing make me recharge the battery about every 3-4 weeks of constant use.

Also, a word about ignition noise. My Honda 550 four cylinder is very noisy electrically. Although it came with swamping resistors in the spark plug caps and I shielded the high voltage wires and coils, none of this had any effect on reducing the noise. I found out that Honda Fours have a very peculiar high voltage system. The ignition coil secondaries are not grounded on one side like they are in a car. They put two spark plugs in series with each other so the spark goes from the tip of one plug to ground, through ground to the other plug and then jumps to the tip of the second plug returning to the coil. So, the problem is that the engine case is a radiator rather than a shield for the spark. The only way I can see around this problem is to use four coils, one per plug, and ground one side of each secondary. Most of the time the ignition noise is down to a comfortable listening level as long as the repeater's signal strength is fairly high. However, when you're trying to receive weak signals the ignition noise can be fierce. Honda Twins (two cylinder engines) are not set up this way. They have a separate coil for each plug. If you experience problems, check your manual to see what kind of system you have. If it can be shielded, do it. Don't forget to add resistor caps and plugs along with any shielding you do, if the engine is not already equipped with them. After adding your improvements, you can use your rig or a transistor AM radio as an rf sniffer to check your thoroughness. Please take note: If your engine performance deteriorates after installing resistor caps or plugs, you may have to go back to the original equipment. Remember, motorcycle electrical systems are marginal. This includes the ignition system, too.

I have been operating motorcycle mobile for about eight months now with good success. Most stations I talk to can't tell the difference between me operating on the motorcycle and other people operating in cars. Frequently, surprised people ask me to repeat what I said when I sign with "Motorcycle Mobile." Then I am usually deluged with all sorts of questions about how other people can do it also.

Now you are ready to enjoy two loves at the same time, radio and motorcycling. I hope this will encourage you to take the plunge and become one of the few stations identifying with motorcycle mobile. ■



First external PTT switch. Hand-held, no bracket.

Inside the Bird

-- a wattmeter exposed

Robert E. Bloom W6YUY
8622 Rubio Ave.
Sepulveda CA 91343

Did you ever wonder how the Bird wattmeter does its thing? I did, after butting my head trying to get a Bendix directional coupler to operate at a power level far beyond its specs. So I started hunting for every piece of design information I could lay my hands on. I found out that the information was not only difficult to find, but also very sketchy when found.

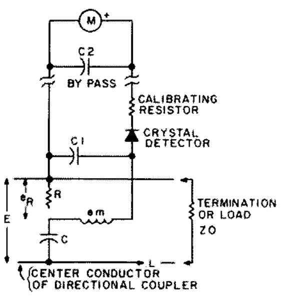


Fig. 1.

The Bird Model 43 wattmeter consists of three main sections: a directional coupler, a detector, and a calibrated readout. Let's start with the unit's readout, which is a very high quality 30 uA (microampere) meter. The meter face is kept simple by having only three basic scales: zero to 25, 50, and 100. The plug-in detectors of varied frequency and power ranges are all made in multiples and divisions of these scales. The meter incorporates about three feet of shielded cable and thus can be separated from the main frame for remote viewing.

The detectors are made to plug into the main frame or housing so that they couple to the center conductor of the directional coupler in a precise fashion for just the right amount of coupling for the specified power rating. The plug-in detectors have precision contacts that connect mechanically to the meter section. By rotating the detector 180° in its socket, one can take both a forward and reverse power reading. By applying the two readings into a simple formula, one derives vswr (the voltage standing wave ratio) on the transmission line:

$$\rho = \frac{1+\sqrt{\emptyset}}{1-\sqrt{\emptyset}} \quad \text{and } \emptyset = \left[\frac{\rho-1}{\rho+1}\right]^2$$

where ρ = vswr and $\emptyset = P_r/P_f$.

I knew that would scare some of you! But look at the formula again with an open mind this time, and see how really simple the formula is. Let's look at $\emptyset$. This is nothing more than the Greek letter "phi" that says the following relates to some voltage, magnetic flux, or angle relationship, and the symbol is easier to use than the equation it represents. In this case, $\emptyset$ or phi is equal to P_r/P_f. P_r is the reverse power reading and P_f is the forward reading. The forward reading is that which you get when the arrow on the detector plug is pointing in the direction of the antenna. And reverse power is that reading when you turn the plug 180° so that the arrow is pointing to the generator or source.

Now, with your calculator, take the forward reading, e.g., 50 Watts, and place it into the denominator (the divisor in the formula). Take the reverse reading, e.g., 5 Watts, and put it into the numerator. We now have $\emptyset$ = 5/50 or .1. Now let's take the rest of the formula or rho resistivity:

$$\rho = \frac{1+\sqrt{.1}}{1-\sqrt{.1}}$$

Take your calculator again and find that $\sqrt{.1}$ = .32. If you can't believe that, multiply .32 by itself and find that it equals .1. ρ=1+.32/1-.32 or 1.32/.68, which equals 1.94, which is the vswr, 1.94 to 1 or roughly 2/1.

Now that you are convinced that you can easily find vswr by measuring two powers, it's even easier to just refer to the curves furnished with the instrument. Then there are no mathematical calculations whatever. But now you know. Let's go on. The detector probe couples to a 50 Ohm cavity, the dimensions of which have been calculated by the relationships of the outside diameter of the center conductor to the inside diameter of the cavity, e.g., Z = 138 log (d_1/d_2). The formula is more involved where the dielectric is other than air.

The cavity in this case is a thruline lumped constant directional coupler; the detector probe or sensor extracts a sample of rf energy

from the line in either a forward or reflected direction. Fig. 1 is a representation of the sensor makeup. It can be likened to an AM detector receiving a CW signal. The signal is rectified and the dc actuates the meter readout.

Basically, the sensor is comprised of a resistor R and a loop of wire which couples to the cavity conductor by mutual inductance M. When the plug faces the forward direction, M is positive. Rotating the plug 180°, M becomes negative.

The capacity between the junction of the resistor R and loop M and the center conductor of the line section makes up the capacity component C. The loop, being a small fraction of a wavelength, will discriminate between the forward and reflected waves.

Looking again at Fig. 1, C and R make up a voltage dividing network. M is the mutual inductance between the loop and the line section center conductor. E is the voltage between the center and outer conductors of the line section. I is the current in the line.

The voltage and power sensitivity are proportional to the distance between the coupling loop and the line section center conductor. Now, looking at the transmission line, the voltage "E" at any point on this line is equal to the sum of the (f) forward and (r) reflected voltage, $E_f + E_r$, and the current "I" is $(E_f/Z_o)-(E_r/Z_o)$. Since the reflected wave travels in the opposite direction, $I_r = E_r/Z_o$,

$$e_{\rightarrow} = j\omega M \left(\frac{E}{Z_o} + I\right)$$

$$= j\omega M \left\{\frac{E_f + E_r}{Z_o} + \frac{E_f - E_r}{Z_o}\right\}$$

$$= \frac{j\omega M}{Z_o} \quad (2\,E_f)$$

and turning the element toward the source, it becomes:

$$e_{\leftarrow} = j\omega M \left(\frac{E}{Z_o} - I\right)$$

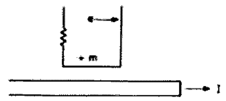

Fig. 2. Element in forward direction.

$$= j\omega M \left\{\frac{E_f + E_r}{Z_o} - \frac{E_f - E_r}{Z_o}\right\}$$

$$= \frac{j\omega M}{Z_o} \quad (2\,E_r)$$

The "j" term simply means that the pickup voltage and current is 90 degrees out of phase with the line voltage and current.

The two formulas show that the rf output voltage from the sensing element is directional and proportional to the voltage in the line due to either the forward or reflected wave. It is also directly proportional to $\omega = 2\pi f$. In order to make it frequency independent, we terminate e in a capacitive reactance which is inversely proportional to ω. The voltage across this capacitor is rectified, filtered, and displayed on the meter scale, calibrated in Watts.

Previously, we stated that E at any point on a line is equal to the sum of the forward and reflected voltage on a flat line (one terminated into its characteristic impedance or one with unity standing wave ratio). The voltage at any point on this line will be equal, as there is no reflected wave ($E = e_f + e_r$). This makes sense as the line is a flat 50 Ohms at any point along its length. If this is so, then the current will also remain constant. From this, the power at any point is equal to $I^2R = IXE$.

However, the line is not always terminated into its characteristic impedance, as some of us well know by past experience. This tells us that on such an improperly terminated line, not only E but also I will vary. Because the wattmeter sensing element's loop M length is a small fraction of a wavelength, we can sample the vswr at any point on the line; both forward and

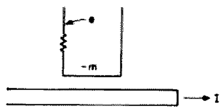

Fig. 3. Element in reverse direction.

reverse current are sampled at the same point and $E = e_f + e_r$. Have I convinced you? I can hear the opposition already.

True, some of you have made measurements on UHF and in essence can show that I and E did not remain constant on your supposedly properly terminated line. I hope you did not use 80' to 100' of RG-58/U. There is a logical explanation for this. At the higher frequencies, it is necessary to use low loss line. If not, the losses in the line will produce data that can give you the impression that you have a well-matched load at the antenna end. 100' of RG-58/U has approximately 3 dB of loss at 150 MHz. Only ½ the power gets up to the antenna, and if the antenna does not look like the feedline, what is reflected is attenuated by 3 dB on the way back. By the time it gets to the source and to the point where you are making the measurement, everything looks rosy. In this case, you might take a second measurement at the antenna end (between the feedline and the antenna). The difference between the power measured at the source and at the load will tell you the loss of power in the line.

Sometimes it is easier to find lower loss 70Ω coax than the comparable 50Ω line. I use CATV semi-rigid and rigid 70Ω line which has a fraction of the loss of RG-8/U at UHF. Before concluding, there is another point of interest to many using a 50Ω Bird and 70Ω or 90Ω coaxial lines. With certain limitations, good results may be obtained on 70 Ohm coaxial cable with a 50 Ohm wattmeter. The insertion of a Bird Mod 43 thruline wattmeter in a line adds 4 inches of 50 Ohm air line plus connectors into the system. This will change the load on the transmitter from its original condition without the meter.

Even on 50 Ohm systems above 100 MHz where the vswr is above 1.5, removing the wattmeter will cause a change. This is so because changing the length of line between a mismatched load and the source transforms the impedance of the load as seen at the source. If the adjustments for maximum energy transfer were made with a feedthru wattmeter in place, removing the meter afterwards will change the conditions. However, conditions on a line repeat themselves every ½ wavelength. The conditions on the line with the wattmeter inserted can be duplicated when the meter is removed by inserting an additional length of coax along with the meter, the total length of 50Ω coax and wattmeter equaling ½ wavelength. Be sure to take the velocity factor (dielectric constant) of the coax and connectors into consideration, removing both meter and added line section as one unit after all adjustments have been completed.

Another interesting method which I use (fully described by WB4KSS in the May, 1975, issue of *Ham Radio*, entitled, "Measuring Complex Impedance with an SWR Bridge") utilizes a double data system of measurements and a computer set of readouts made from a series of Smith chart plots. This method is especially good when using a 50Ω bridge and transmission lines of higher impedance.

Many hams now possess the treasured 50Ω wattmeter. With a little understanding of its abdominal functions, you should be able to find more uses for it than just measuring the output power of your transmitter. More power to you! ■

Introducing Autotrak!

-- digital antenna tracking system

It has been a long time (over two years) since the big winter wind (I swear it was Murphy's big mouth) took down our first EME array attempt. The horizontal boom (40' tower) was too weak, the drive system left a lot to be desired in the elevation mode and was not too great in azimuth mode either, and so on. Oh well, live and learn.

In this article I hope to point out some of the corrections for any of you enterprising large array freaks like me, and also explain the most advanced — and in the future useful — piece of electronics added while we were down and muttering through the chill of two winters.

The electronics improvement I'm referring to is the Autotrak. If you are not interested in the EME work, don't stop reading now. How about all of you OSCAR fans? Want to track that little devil automatically so you can concentrate on making contacts and not have to grow six hands? Read on. Also, how about you die-hard contest ops? This unit will swing the beam around to precise headings on any preset timetable, and you choose the timetable!

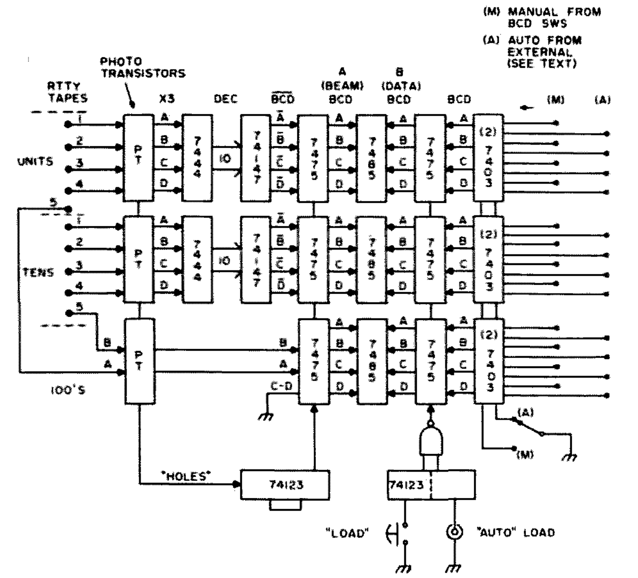

Fig. 1. Autotrak block diagram shown for azimuth (3 digits). Delete 100s for elevation. Elevation note: 5th line holes used for determining north or south quadrants in elevation (- or +). See schematic for details.

The antenna array here is an el-az type driven in elevation and azimuth, not a polar mount. This makes it a little tougher to track celestial objects (i.e., the moon), but it is much easier for satellites, tropo, etc. To give you some idea of our setup, there are sixteen 11 element Cushcraft modified 147-11 yagis mounted for horizontal polarization, approximately 1 wavelength apart from each other in both horizontal and vertical dimensions. This gives an overall array size of approximately 36' wide (tower), 20' top to bottom (vertical masts), and 12' deep (antenna booms). Big, in other words! This leads to special problems, but none that can't be overcome with a machine shop, super mechanical ability, or a Jeep engine for a rotor. The azimuth drive is handled by the old-time ham's workhorse — the prop-pitch motor ($3.00 at hamfest), the transformer for its power ($1.00 as a military surplus battery charger transformer — tapped input, tapped output, 20 Amps — hamfest), shaft coupler to absorb shaft misalignment (3/4" plywood doughnut and 1" x 3/16" flat steel — big oversize flexible coupler — hardware store parts), 4 heavy duty wheels for a lazy Susan type arrangement on top that allows rotary motion in azimuth (scrapped off factory package cart with 3' x 5' bed, 4" wheels with roller bearings, super heavy duty, and free), constructed wooden "doghouse" that tower lays in on 4 more of the cart wheels (plywood, well varnished and painted — wood *can* survive outdoors if you do it right). So much for azimuth.

Elevation is accomplished by building up a triangular tower (ours is Spaulding HDX) so it is circular in two places (more 3/4" plywood, double thickness) and putting 1" x 3/16" strap steel around it to form 2 metal rim "wheels" spaced just barely wider than the doghouse width. More package cart wheels are used as "bearings" (4), and the tower rotates along its own centerline. Therefore, anything attached to vertical booms running 10' above and 10' below the tower horizontal centerline remains in balance as the whole tower is rotated. This means you only have to overcome the metal rim "wheels" to package cart "bearings" friction. To do this and get the kind of resolution you need, use a pair of RCA through type rotors mounted horizontally to the back floor of the doghouse with a 1¼" o.d. waterpipe between them and through both. This becomes the drive "drum" for aircraft cable drive that push-pull drives a drum built around the center of the tower in the doghouse. This drum is constructed much like the tower metal rim "wheels." Two wooden discs form the outside edges and cable "guides," and ¼" x 20 3" long bolts are passed

between them from alternate sides every 2" on a diameter that just touches the three tower legs. The wooden guide edges are made 1" larger than the bolt circle to hold the cables on the bolt circle. The bolts themselves are covered by another piece of 1" x 3/16" strap steel formed into a drum over the bolts. Cables are fed 1 turn around the drum and then to the pipe drive drum. One cable goes one direction around the drum and the same way around the drive drum (pipe). The other cable goes the opposite way, for a push-pull action. Sufficient cable turns are placed around the drive drum to allow the tower to turn through a full 180°, or full front over top to full rear. This allows full 360° azimuth and 180° elevation coverage, but only requires the actual azimuth to turn 180°, east through south to west. West through north to east is taken care of by bringing the elevation up from 0° through 90° and on over into the north quadrants. Some may question the inverted horizontal polarization. One, we don't see any difference at all in the tests we ran. Two, very little work will be done in the north quadrants anyway except for initial North Star sighting and original bearing calibration.

This has been a rough detail of what we run, and an article will follow describing things in detail with (hopefully) many pictures, but you can see the problems with steering and tracking such a large array with such narrow beamwidths, both horizontal and vertical. You can't imagine how small that moon can be until you go looking on a cloudy night when visual tracking is out.

This brings us to our answer to steering this whole beast. The electronic tracking control is all TTL IC type quite common nowadays, and cheap! First, I'll try to describe it in function and peripheral equipment, and then by circuits.

In general, from the antenna end, two paper or mylar RTTY type "tapes" mount to a round clear plastic cake pan that is mounted to the azimuth shaft. These tapes are easily done by yourself or a fellow amateur with RTTY gear. They are punched using the Baudot holes, but the code is *not* Baudot. It requires all 5 holes for one number in Baudot, or 15 holes (three tapes) for the azimuth readings. I devised a "fake" code table that will allow you to punch the two tapes using the letters common on the "green keys," but the holes that result are later read as follows. One tape (top in our case) is called units and represents the ones of degrees on lines one to four. The hole code if you read it as line 1 = A, line 2 = B, line 3 = C, and line 4 = D, is really Excess 3 gray code. The advantage is that as each number changes up or down a degree at a time, only one A, B, C, or D line changes, unlike BCD or binary where many often do (i.e., in BCD 7 to 8 transition, all four change!). This helps in error reading reduction, settling time, etc., and much more than we can go into here. It works much better, ok?

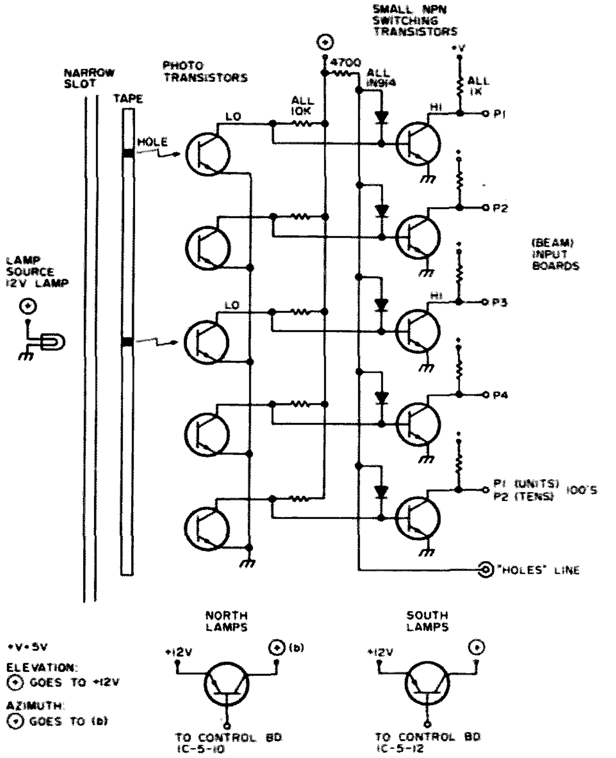

Fig. 2. Lamps and photo transistor "readers," 6 for full system: 2 elevation, 2 north quadrant az, 2 south quadrant az.

These tapes are fastened to the clear cake pan rim or side walls and are read by a lamp source on the inside and a phototransistor type pickup outside (5 per tape, see detail).

The second tape is called a tens tape and lines one to four carry the 10s of degrees in Excess 3 gray code much like the units tape, but the preparation or encoding is *quite* different. We manage to "fake" the two tapes into taking care of the three digits

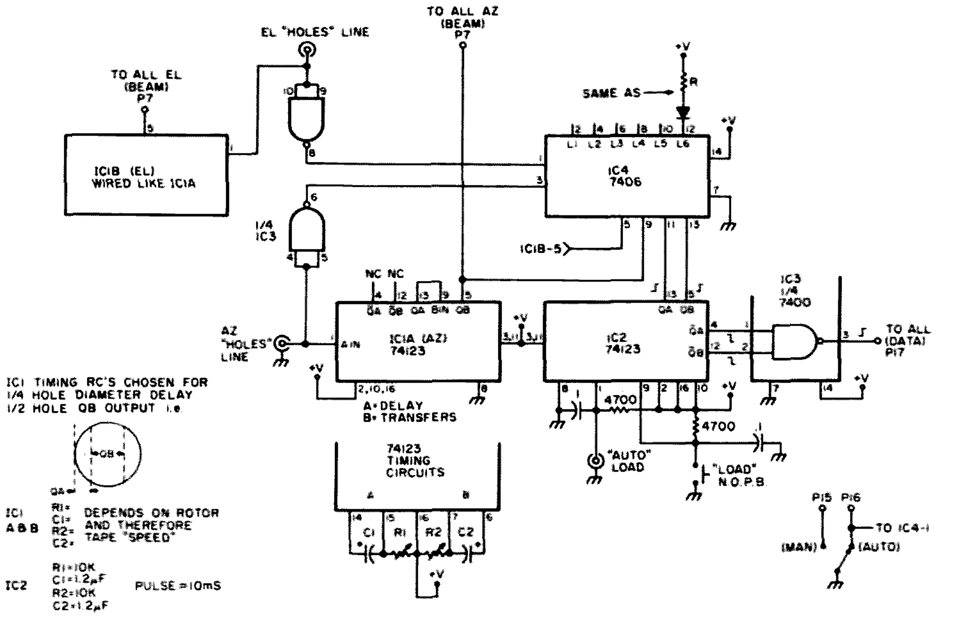

Fig. 3. Control and status board and front panel, part 1. L1 — holes detected, el; L2 — holes detected, az; L3 — beam input transfer, el; L4 — beam input transfer, az; L5 — auto-load; L6 — load. R to suit LED I limits (<40 mA).

by using the fifth line of the Baudot tapes to carry the 0-1-2-3 figures of 100s of degrees.

This is done as follows: On degrees 000 to 099, the Baudot letter is used that cuts the proper gray code on tape one and proper gray code on tape two on lines 1 to 4 respectively, and yet does not punch a hole on line 5 of either tape. Or, line 5 of each tape is a blank (no hole) (0,0), or B = 0, A = 0, decimal zero.

On degrees 100 to 199, the Baudot letter is chosen on the units tape that causes the proper gray code for units, but adds a hole in the fifth line. The tens tape is punched using the same letter system of 000 to 099 degrees using no line 5 hole. Or, line 5 on tape units is a hole, and tape two tens is blank (no hole) (0,1), or B = 0, A = 1, a decimal one (C and D are understood zero and are not needed to represent any number from zero to four).

On degrees 200 to 299, the fifth line hole combination reverses (1,0), or B = 1, A = 0, a decimal two.

On degrees 300 to 360 (399 possible numbers, but only 360 degrees), both tapes have the fifth line hole (1,1), or B = 1, A = 1, a decimal three.

You may now have noted the output from the fifth lines are the 100s information in direct BCD code. It seems to be OK here since the transitions only occur infrequently and at three places in the entire 360 degrees (099 to 100, etc.).

To use the gray codes from the 1s and 10s, you must convert it to BCD for use in TTL comparators. I use SN7444 gray code to decimal ICs to do this, then use SN74147 ICs to go from decimal to $\overline{\text{BCD}}$. This $\overline{\text{BCD}}$ is fed to the inverted arrangement shown in the SN7475 latches, and when the transfer line goes high, it is transferred to the A0 to A3 inputs of the 7485 comparators as BCD, right side up. More on the transfer lines later. The 100s of azimuth are fed directly to the 7475s, then 7485s. All azimuth 7475 transfer lines are tied together.

From the data input end, let's cover the manual mode first. This is a mode where you can enter a "go to" degrees command via a set of 5 thumbwheel BCD output switches like many synthesized 2m rigs now have. The outputs of the first three switches (azimuth) are gated through manual/automatic gates to 7475 latches. The transfer lines of these latches are fed from one half of a dual one-shot 74123. That half is fed by a panel pushbutton marked "load." To use this mode, information is put into the switch in decimal form the way you think for 100s, 10s, and 1s of degrees, the manual/automatic (man/auto) is placed in manual, and the "load" switch is momentarily depressed. The one-shot puts a nice clean high pulse on the transfer lines, and the gate information fed into the manual (M) gates is transferred to the 7475s and held there. That's all there is to it.

A brief word of explanation is in order here. Since all of our towerhouse gear is remote controlled by wire from my basement, the only time the system does not then go immediately into search or motion automatically is when the power off switch is placed to off. *Any* other time the antenna position information (BEAM) does not agree with the output information from the man/auto side 7475s

(DATA), the antennas move to correct this. Thus if for any reason (wind, etc.) the antennas move away by themselves, they are automatically correct as soon as the gray code error is noted — assuming the power is on. This neat feature has many side benefits. For instance, if you look back to the Nov., 1976, *73 Magazine*, page 84, article by me, you will see a wind indicator device whose output is in degrees and BCD code. That device was no accident, and if fed into the automatic inputs of this control unit, and the unit left in automatic mode and on, the beams will always face into the wind! In some parts of this country, that almost makes these two projects worthwhile on that reasoning alone. Our tower horizontal section is braced, etc., such that our best way is facing into the wind. I would advise, however, you only sample and compare 100s and 10s of degrees to keep the array from forever "hunting" and burning out motors, etc.

In the automatic mode, information (DATA) from the automatic mode gates (A) is routed to the data 7475s. It is transferred only when the transfer line is brought high. This is accomplished in the auto mode by any TTL level low applied to the auto-load input connector.

I failed to mention the single gate that allows tying both outputs of the 74123 to the latch line. I'm sure you are all doing your *73* reading and I/O homework, but since it is an inverted use of a NAND gate 7400, I'll explain. The inputs to either 74123 are low going transitions. This creates a pulse output determined by the RC chosen for each one-shot. You then use the normally high output of each 74123 to feed the 7400 inputs. Normal condition is (with no inputs) both 7400 inputs high, output or transfer line low, no transfer. If either input sees a low transition, the one-shot goes low, the 7400 output goes high, and transfer occurs.

Skipping where the automatic input (DATA) comes from for a minute, the auto transfer input in our case has several possibilities. Of course the "load" push-button is one of them, even if the man/auto switch is in auto. Another is an S.D. Sales 60 Hz timebase driving one of our older TTL real time clocks, and the 1 ppm, 1 p/2m, etc., lines brought out through a rotary switch (you obviously want new data faster, more often, on OSCAR than with EME) and a BNC jack over to the beam control (Autotrak) unit, which incidentally will be all buttoned up in a Drake TR-6 case when finished to match the rest of the console, to give you some idea of size. Another source for use on schedules, and for our eventual use remote from Indy stations and members of ECHO, is a set of 7485 comparators added to the old clock and four more BCD switches. You dial in a time in hours and minutes (4 digits — GMT) and at the appointed hour it turns on many things in the station via the A = B output (high) to the 6 inputs of a hex inverter/line driver IC whose outputs (low) do the controlling. One of these lines (low) turns on the antenna control, another "hits" the transfer line indirectly. Since these outputs are there for the full minute

Table 3. Baudot to X3 Gray Table.

the clock and switches agree, plenty of time is allowed for a positive control. A tape in our case (RTTY) is loaded into the tape reader and set on the first set of holes representing the 100s of degrees of azimuth. For your own information and for future articles, all of our data information will be in azimuth-elevation, 100s, 10s, 1s, 10s, 1s format, i.e., 10545 is 105 degrees azimuth and 45 degrees elevation.

A decoder for Baudot (numbers only) to BCD accepts the tape information in parallel from the reader, using the stop pulse to transfer to the next memory latch (digit). 7475s are used here also, but the data control unit is the subject of the next article, so more on it there. The control mode is as follows, however: (1) it is time to read tape – 1 ppm from clock, etc.; (2) This pulse turns on the tape reader FF and therefore the tape reader; (3) As long as there is tape in, reader tape advances, putting info into the latches; (4) When the fifth digit is loaded (az-el), a pulse is formed in the data control unit, resetting the tape reader FF, shutting off the tape reader, and the same pulse "hits" the (DATA) side 7475 transfer lines; (5) 7485s compare data and run beams to new headings as required.

You will no doubt realize, too, that a UART having ASCII output has lines 1 to 4 already in BCD code for numbers. You can now detect the serial stop pulse to advance the memory latches and have a keyboard input. Baudot owners can run in the FIGS mode into our control unit and do the same thing. You may recall my rotary dial decoder also in the Nov., 1976, *73 Magazine*, and it is mentioned in there the control device used here as a data control unit. It works very similarly to the dial decoder, since one was an outgrowth of the other.

Due to their general lack of use until recently in amateur

gear, the 7485 may seem a bit strange to you. The cascade inputs on these devices work great, but be careful to hook up as shown with the LSB digit getting the hardwired inputs, and the outputs coming from the MSB digit (azimuth 100s, elevation 10s). Reverse it and you are in for some real surprises. When you are working the underside of a board, it is easy to transpose LSB and MSB digit. Please don't ask me how I know this so well — nobody's perfect!

The elevation works just the same way as azimuth with one less number to worry about. We use linear tapes punched the same as for azimuth; it's just easy to get them in the doghouse that way rather than around a drum. Same data table applies. The same decoding, comparing, data in, all works the same.

For those of you who have counter (digital counting, readout type) dials on your receivers now or are planning it, consider our much modified BC 348s for a minute. If we use a dc drive (sawtooth waveform) to control the varactor group to "scan" the receiver, something very similar to this article has proven very useful and will be an upcoming article when we get back to the Space Age Junque series. Meanwhile, I'll let you brave ones ponder it on your own.

One: thumbwheel switches for a BCD frequency input. Push the auto scan button and an FF starts the scan. The final 7485 comparator A = B output stops the scan at the desired dialed-in frequency.

Our system does not really use sawtooth scan, though it looks like it does. When the auto scan button is pushed

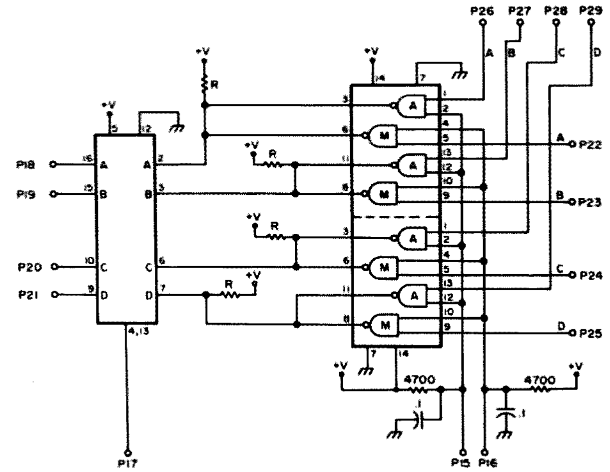

Fig. 6. Data input boards, 5 required. R = 1k.

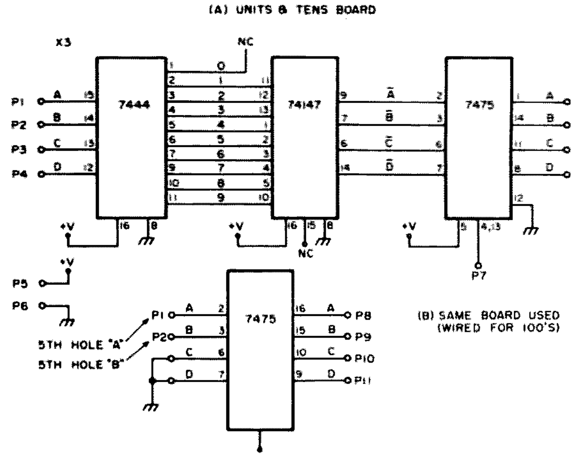

Fig. 7. Beam input boards. 4 wired (a) Az – 10s, 1s; El – 10s, 1s. 1 wired (b) Az – 100s.Ɔs.

(or is called up remotely from Indy), the FF for this starts the scan by turning on the "charge" switch (transistor) of a dc memory module similar to the RCA remote control memory modules of a couple of years ago. The memory output is 1 to 10 V dc and controls the frequency varactors. There *is* a counter on the BC 348 for a dial readout (348 rack mount, readout, control, master oscillator, etc., console mounted), and the counter begins to follow the frequency upward. Upper limit is a set of jumpers to hardwire upper and lower limit gates. A stop command, AFC zero crossing plus AGC (station heard), or output from counter = limit switches comparison in 7485s, will stop the up scan. In the first two cases it is stop and hold, and in the latter it tells the scan FF to reverse. The "discharge" switch in the dc memory module takes over and causes a downward scan with the same features. Keying of the transmitter will generate a stop command and hold followed by a one-shot delay in resuming after carrier drop (sense COR on incoming remote link receiver).

One more? OK, last one for now. Consider we have a receiver with a counter dial. Doesn't take much to have a receiver with digital AFC, does it? You can ponder that one awhile – it takes one more IC!

SASE if you have problems. This should reduce the Bufferin sales to OSCAR users. ■

A Battery Voltage Monitor

-- how simple can an IC project get?

A device introduced by Litronix, Inc., has wide application as a voltage monitor in all types of battery-operated equipment. The RCL-400 Battery Status Indicator is a current-controlled LED which has a voltage sensing integrated circuit incorporated into a small LED package.

The only additional circuit component necessary to build a voltage monitor is a suitable zener diode, or string of forward biased diodes, to bring the device into its normal operating range. The RCL-400 is designed to turn *on* at 3 V and *off* at 2 V; thus normal operation can be provided by selecting Vz = Vcc - 3 V (See Fig. 1). When Vcc drops to Vz + 2 V, the LED is switched off by the internal IC voltage sensing circuit to give a low voltage indication. Since the device has a relatively constant current demand in the *on* region (~ 10 mA), the zener power rating need only be ¼ W for most battery-powered equipment. One precaution is necessary: You must be sure that the voltage across the LED does not exceed 5 V (its maximum rating).

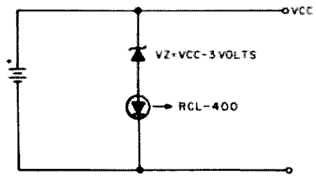

Fig. 1.

For low voltage IC circuits using a nominal 4.5 V battery pack, the required value of Vz is only 1.5 V. It is easy to obtain this value by simply substituting a pair of silicon diodes in series with the LED. ■

The Morse Clock

-- timely repeater ID

Robert J. Souza WA1MXV
46 Fielding St.
New Bedford MA 02745

A clock which sends the time of day in Morse code can be a useful addition to any modern repeater. Aside from providing mobiles with the correct time of day, the clock may be used to write the time of day on cassette tape for logging purposes when an autopatch or other event occurs. This article describes such a clock constructed for the WR1ADR 60/00 repeater in South Dartmouth, Massachusetts.

The Morse code clock has the following features:

1. Low chip count (17 ICs compared to 30 in previous designs).
2. Easy timesetting (hours fast, minutes fast and hold).
3. Variable code speed.
4. Six digit LED time display (impressive).
5. Protected against power failure (won't lose time).
6. Time may be sent to either 12- or 24-hour format.

Circuit Description

The heart of the Morse code clock is a National MM5318 PMOS clock chip (Fig. 2). This chip was designed to be used in a system which displays the time of day on a television screen. Unlike most other clock chips which have only multiplexed seven segment outputs, the 5318 has both seven segment and $\overline{BCD}$ outputs available. Furthermore, each digit (hours, tens-of-hours, etc.) may be selected for output by applying the proper code to the Dx, Dy and Dz digit select lines. This is ideal for application in the Morse code clock, since we want to be able to look at the digits one at a time in order to translate them into Morse and send them. The clock requires either a 50 or 60 Hz input signal. This may be obtained from either the power line or a crystal time base. (More on this later.) The clock chip will operate in either a twelve or twenty-four hour format and has leading zero blanking in the twelve hour mode.

The Design Technique

I decided that a straight-

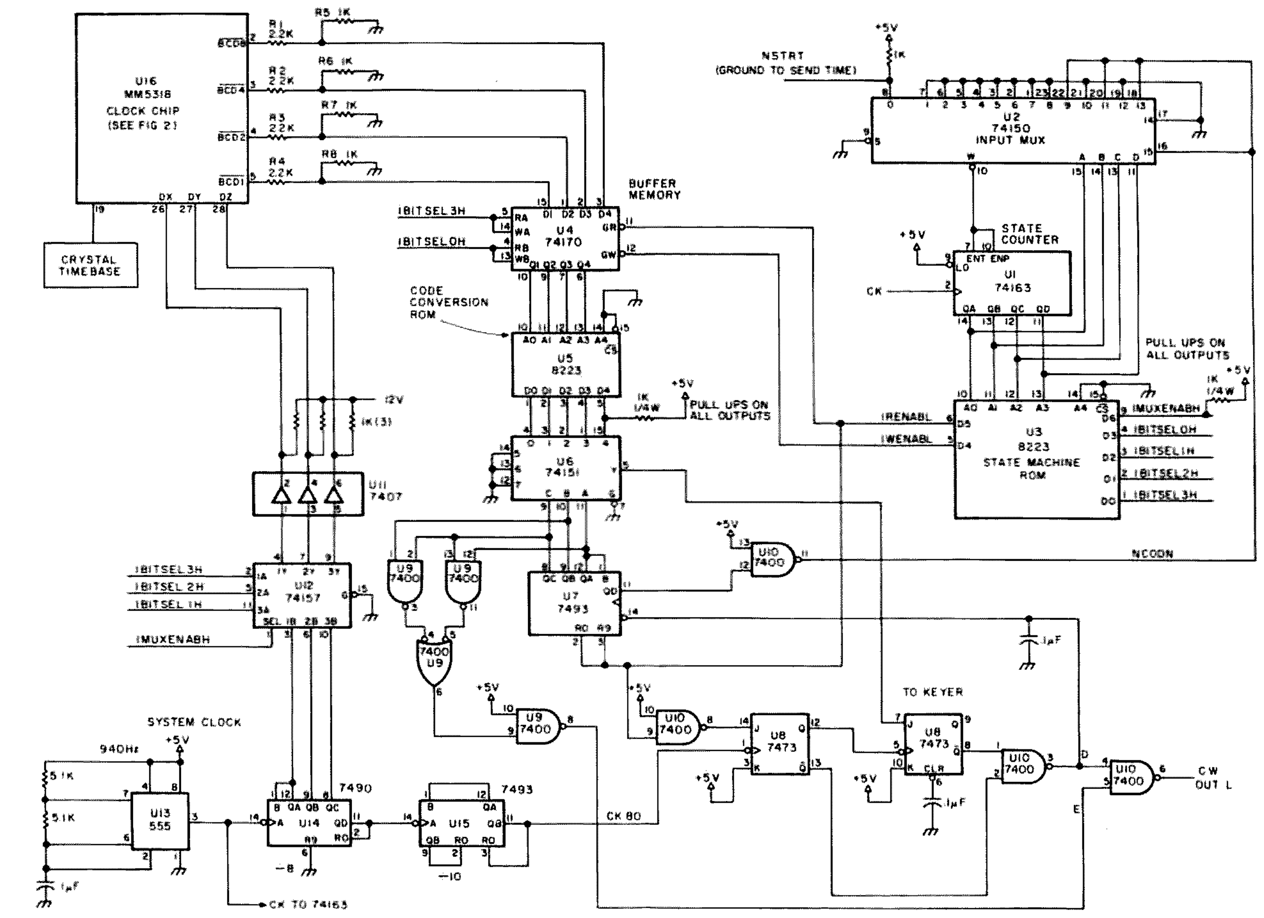

Fig. 1. Morse code clock.

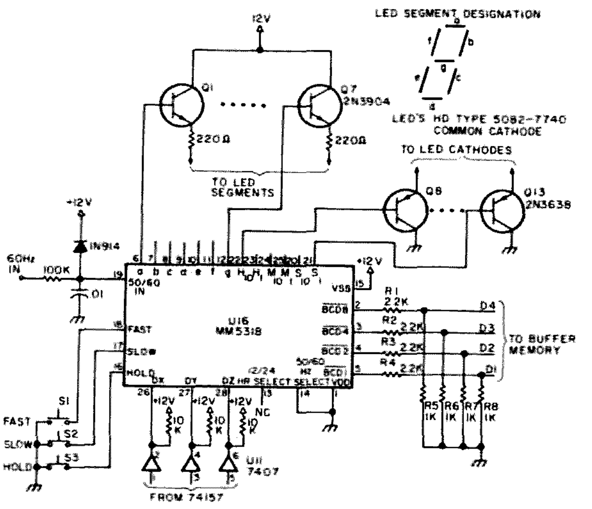

Fig. 2. Clock chip and display circuitry.

forward way to design the clock was to use the *algorithmic state machine* or ASM design technique. This is a very popular and powerful technique that is often used for the design of computer central processing units (CPUs).

The first step in the ASM technique is to decide exactly what you want the device to do. I did this in the *operational flow chart* of Fig. 3. Initially the clock sits with its seven segment display multiplexed and waits for a START signal. When it receives this signal, it rapidly stores the time of day in a buffer memory. It then reads the digits out of the buffer one at a time and sends them in Morse code. After the last digit has been sent, the display is again multiplexed and the clock waits for another START signal. The time of day must be rapidly read into the buffer because it is possible for the time of day to change while it is being sent. This could cause an error. Consider the case where the time changes from 2359 to 0000 after the first digit (the "2") had been sent! Rapidly loading the time into the buffer minimizes the chance of an error occurring.

Fig. 4 shows the *system block diagram* for the Morse code clock. A ROM centered state machine controller is driven by the system clock and controls three peripheral circuits. These are the clock chip and display, the buffer memory, and the BCD-to-Morse converter.

System Clock (U13, U14, U15)

The system clock is an LM555 timer IC wired as an astable multivibrator with a free running frequency of about 940 Hz. It is divided by a 7490 and 7493 counter (U14 and U15) to about 12 Hz for use in the BCD-to-Morse converter. The output lines of the 7490 (U14), which are varying at a 940 Hz rate, are used to multiplex the seven segment display when the clock is not sending the time.

The State Machine

The state machine controller is made up of U1, U2 and U3. These three chips control the operation of the rest of the circuit. U1, a 74163 4-bit synchronous counter, is the state counter. Its binary outputs determine the present state. There are sixteen possible states for this machine.

The state counter is driven by the system clock, but the only way to have it advance to the next (sequential) state is to have a logic "1" present on the 74163 enable inputs (ENT and ENP). The enable inputs are connected to the output of U2, a 74150 16-to-1 data selector. U2 is the input multiplexer. It acts like a single pole, 16-throw logic switch. The input select lines of U2 are connected to the state counter output lines, so that we look at a given input in each state. The way to advance to the next (sequential) state, then, is to have the selected input condition be true. (Note that the output of the 74150 is inverted, so for the output of the MUX to be true, or logic "1", the input must be false, or logic "0".)

U3, an 8223 32 x 8 ROM, is called the *state machine ROM*. Its address lines are connected to the state counter's output lines. In any state, the ROM may be programmed to generate any combination of eight possible outputs. (Only seven of the outputs were needed for the Morse code clock.) The ROM is simply a replacement for the combinational logic (NAND and NOR gates, etc.) which would be required to generate the outputs. The contents of the state machine ROM are shown in Fig. 5.

In a given state (as determined by the state counter output lines) certain outputs are issued from the state machine ROM and a given input condition is tested by the input MUX. If the condition is false, the machine remains in the present state and continues to issue the outputs required in that state. If the condition is true, the machine advances to the next sequential state on the next positive transition of the system clock. This is often represented graphically as in Fig. 6, which illustrates the case in which the machine waits in state A, corresponding to state counter output 0010, and issues output LITEON (which is active-high as indicated by the H prefix) until input PUSH goes to 0.

A little thought will reveal that this is a very powerful design technique. Since the outputs are programmed into ROM, they may be changed by merely reprogramming, without making any circuit

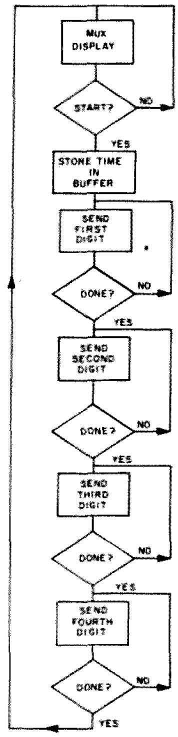

Fig. 3. Operational flowchart.

1111	0	0	1	0	1	0	0	send fourth digit (minutes)

Fig. 5. Control ROM program.

changes.

Clock Chip and Display

The features of the MM5318 clock chip have already been described. U11, a 7407 high voltage open collector buffer, acts as an interface between the TTL and MOS logic levels for the clock chip Dx, Dy and Dz lines. U12, a 74157 quad 2-to-1 MUX, acts as a 4PDT logic switch and causes the binary code applied to the MM5318 digit select lines to come from either U14 (which causes the display to multiplex) or from the state machine ROM. The 74157 is also controlled by the state machine ROM. R1-R8 are voltage dividers and convert the MOS levels out of the clock chip to TTL levels. Transistors Q1-Q13 and associated resistors are used to interface the common-cathode LED display to the clock chip. Pin 19 of the clock chip is the 50/60 Hz input. For 60 Hz input, ground pin 14, for 50 Hz,

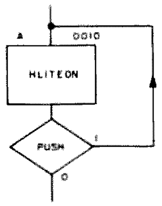

Fig. 6.

leave it open. If you choose to use a crystal timebase instead of stealing the 60 Hz from the power line, the 1N914 and RC network at pin 19 may be eliminated. The timebase I used was purchased from S. D. Sales and assembled according to their instructions. It was cheaper to buy the timebase from S. D. Sales than to build my own. S1-S3 are push-button switches which are used to set the time.

The Buffer Memory

U4, a 74170 4 x 4 register file, is used as the buffer memory for the time. The time of day output from the clock chip (in $\overline{BCD}$) is written into and read from the buffer memory under direct control of the state machine ROM.

$\overline{BCD}$-to-Morse Converter

The output of the buffer memory is connected to the address lines of U5, the 8223 code conversion ROM. This ROM converts $\overline{BCD}$ to an intermediate code in which a 0 represents a dit and a 1 a dah. The contents of the code conversion ROM are shown in Fig. 7. Note that the ROM will convert a blanked first digit (which occurs when the clock chip is in the twelve-hour mode) to a Morse code 0. Say, for example, that a "7" (1000 – remember, the BCD is inverted) is input to the ROM. 00011 will appear on the ROM output lines. With reference to the schematic and the timing diagram (Fig. 8), when the state machine brings RENABL low, U7, a 7493 counter, is enabled, and the 74151 MUX (U6) passes the least-significant bit of the ROM output (a "1" in this case). U8, a dual J-K flip-flop, and NAND gate U10 make up a variation of the well-known TO keyer. The "1" on the MUX output causes the TO keyer to send a dah. U7 clocks on the falling edge of the dah causing the MUX to select the next most significant bit of the ROM output. After the five bit ROM output has been scanned and sent, the MUX selects input lines 5, 6 and 7, which are hardwired to logic "0". This will cause three additional dits to be sent. U9, a 7400, blanks these dits and they form the space between numerals. After five code elements and a space have been sent, output NCODN goes low, signalling to the state machine that a complete Morse code numeral, including space, has been sent. The state machine may then bring RENABL high to reset the converter, present new $\overline{BCD}$ data (by changing the buffer memory address), and bring RENABL low to repeat the sequence.

In summary then, if $\overline{BCD}$ data is presented to the $\overline{BCD}$-to-Morse converter input and RENABL is taken low, the $\overline{BCD}$-to-Morse converter will generate the sequence of dits and dahs corresponding to the inputted data, a three dit space, and then signal that is is finished by taking NCODN low.

The ASM Chart

Fig. 9 shows the ASM chart for the Morse code clock. It shows all the states, the outputs issued in each state, and the inputs required to advance to the next state. If no input condition is shown in a given state, it is assumed that the machine advances to the next sequential state on the next positive transition of the system clock. A table of the state machine inputs and outputs is shown in Fig. 10.

Power Supply

The power supply for the Morse code clock is shown in Fig. 11. A 12.6 volt 1.2 Ampere transformer (from Radio Shack) is used in a full wave bridge to provide 12 volts for the display and the clock chip. An LM309K regulator (mounted on a heat sink) provides a regulated 5 volts for the TTL logic. Diodes D1 and D2 are used to automatically switch in a nicad pack if the power fails. Note that the nicads will reverse-bias D1, turning off the display when the power fails to conserve current. R1 is used to trickle charge the nicads and should be selected to provide the required charging current.

Construction Notes

The clock was built on a wire-wrap prototyping board. I like this method of construction because it allows me to test the circuit as I build and also allows for easy modification (and correction of mistakes!). The wire-wrap board was mounted in a 9" x 11" x 2" chassis along with the power supply and time

Digit	ROM Address	ROM Contents
0	1111	11111
1	1110	10000
2	1101	11100
3	1100	11000
4	1011	10000
5	1010	00000
6	1001	00001
7	1000	00011
8	0111	00111
9	0110	01111
blank	0000	11111

Fig. 7. Code conversion ROM contents.

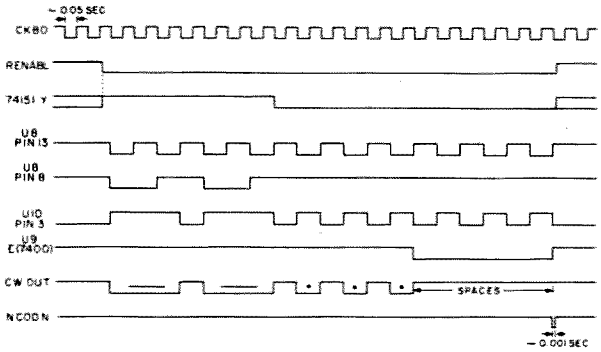

Fig. 8. BCD-Morse converter timing diagram.

setting buttons. The six digit LED display was mounted on the front panel of the repeater in an IEE six readout mounting bezel which was purchased from Tri-Tek. This bezel makes a very professional looking and reasonably inexpensive display. The LED display is connected to the clock with a 14 wire ribbon cable.

The clock tends to run quite warm (especially the ROMs and the Buffer Memory) so I punched six 1" holes around the perimeter of the chassis. The holes were covered with perforated aluminum to complete the shielding of the clock.

The clock chip and the chip in the crystal timebase are MOS devices and as such are susceptible to damage from static discharge. Handle them with care. Do not remove them from their protective packaging until ready to install them. Do not insert or remove them from the circuit with the power on. If you choose to solder these chips in, ground the tip of your soldering iron.

The programming procedure for the Signetics 8223 ROMs has been described many times before and will not be repeated here. The references at the end of the article should be consulted for the proper procedure.

Vcc was bypassed to ground with 0.01 uFd 50 volt ceramic capacitors at the rate of one capacitor for every three ICs. Do not omit the 0.1 uFd capacitor from pin 6 of U8 to ground. It performs a power-on reset for the flip-flop. The capacitor in the system clock circuit determines the system clock frequency and ultimately the CW speed. If a cheap ceramic capacitor is used here the CW speed will change as the clock heats up. I used a sealed mylar unit.

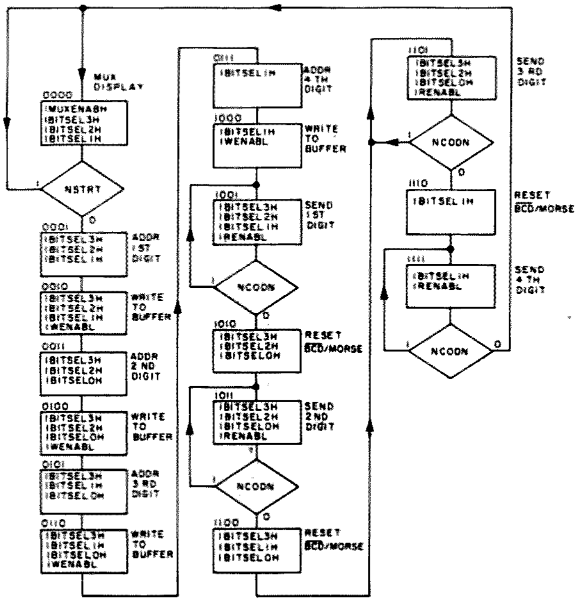

Fig. 9. Morse clock ASM chart.

Interfacing the Clock and Repeater

All interconnections between the clock and the repeater control logic are active-low. This allows the clock to be removed from the repeater without affecting the repeater logic.

Grounding input NSTRT will start the time sending cycle. NSTRT should return to 5 volts before the clock is finished sending the time or else it will repeat. In our repeater NSTRT comes from the touchtone™ decoder output. The clock is activated by a single touchtone digit.

Output IMUXENABH goes low during the time sending cycle and may be used to hold the repeater transmitter on.

CWOUTL is the active-low CW output from the clock. It may be used to drive an audio oscillator as shown in Fig. 12 if none is available in the repeater.

Push-button switches S1 and S2 cause the clock to advance one hour per second and one minute per second respectively. S3 will stop the clock for synchronization to the exact second with WWV or CHU.

When the clock is first powered up it may begin sending the time. It will cycle once and then stop. Also, all the digits in the display may not be illuminated. Merely advance the clock with S1 and S2 until all the digits light up. It is a good idea to cycle the clock through all 24 hours when first powering it up, since it is possible for it to count up to 30 hours the

State Machine Signals

OUTPUTS

IBITSEL3H IBITSEL2H IBITSEL1H IBITSELOH	select clock digit and buffer memory address
IWENABL	when low, writes time into buffer
IRENABL	when low, reads time from buffer and sends it in Morse
IMUNENABH	when high, causes LED display to multiplex, when low causes clock digit to be selected by IBITSELO-IBITSEL3

INPUTS

NSTRI	goes low to start time sending sequence
NCODN	goes low to indicate that a complete numeral and space have been sent in CW

first time through.

Changing the CW Speed

The speed of the CW output is determined by the frequency of CK80, the input to the BCD-to-Morse converter. The output speed is equal to 1.2 times CK80, in wpm. CK80 in my clock is 940/80, or 11.75 Hz. The output speed is then 1.2 x 11.75, or 14.1 wpm.

CK80 *may* be varied by changing the value of the 0.1 uF capacitor in the system clock. This is not really a good idea, since the system clock is also used to multiplex the seven segment display, which will flicker if the multiplex frequency is too low. A better way to alter the CW speed is to change the division ratio of U15. Say, for example, that an output of 10 wpm is needed. CK80 must therefore be 10/1.2, or 8.33 Hz. This requires a division ratio in U15 of 94/8.33, of 11.28. If U15 is set to divide by 12 (by connecting pin 2 to pin 8 instead of pin 9), the output speed will be 9.4 wpm. The CW output speed may be varied from 9.4 wpm to over 100 wpm by merely changing the division ratio of U15.

Getting the Parts

At the time of writing, nearly all of the parts for the Morse code clock were available from James Electronics. I bought the HP 5082-7740 common cathode seven segment LED readouts and the crystal timebase from S. D. Sales. The chassis and other odds and ends were obtained locally.

Thanks to the ASM design, the Morse code clock worked immediately when powered up. It has been in operation at the WR1ADR 60/00 repeater in South Dartmouth MA for about six months without any problems. My thanks to K11BR and the rest of the crew at SEMARA for their cooperation and support. I will be glad to correspond about the Morse code clock or ASM design. An SASE would be appreciated. ■

Hunting Noise

- - with a grid dipper

John P. Dieringer W6RVP
9010 Ramsgate Avenue
Los Angeles CA 90045

Noise external to receiving equipment can sometimes be difficult to pinpoint. A spectrum analyzer is beyond the reach of most amateurs. Here is a cheap substitute that has been proven.

Some time ago man-made interference was tearing up communications across a wide spectrum, seriously upsetting some military operations. Engineers tried to solve this with a spectrum analyzer and failed. As hams, a friend and myself were asked if we could solve this. A little thought as to why the engineers failed led us to the conclusion that their equipment was too sophisticated. I devised the idea of using my Heathkit grid dipper and a scope. The scope was hooked to the internal dipper diode and ground. At 2 MHz there was plenty of grass when the dipper coil was placed near any building wiring. Reducing the scope sensitivity, the grass was barely noticeable. We probed around. It didn't take long to locate a relay used for aircraft obstruction lights that was defective, with pitted chattering contacts.

Any battery operated dipper can be used. It can be hooked up to the audio section of a battery operated portable radio for use away from the shack. Make sure the dipper switch is in the diode position, so it is being used as a field strength meter. To hook the dipper up, solder one wire to the output side of the dipper diode and the other wire to ground. These wires go either to the scope vertical input or, in the case of a radio, to the volume control. Do not wire to the volume control center tap.

Tuning the dipper to harmonics, hunting parasitics, or debugging a transmitter is easy, too, since the scope gives an excellent visual display. ■

CMOS Oscillators

-- practical techniques

Over the past few years, many articles have appeared in various electronics magazines dealing with the subject of oscillators and their applications. Of these articles, the majority have dealt primarily with transistor and TTL circuits.

While these devices have performed exceedingly well in many applications, there are other devices available that may be more suitable for certain applications. For example, CMOS devices perform well in low power circuits and can operate satisfactorily from a wide range of supply voltages (typically +3 to +15 volts). These two features make CMOS devices ideal for compact, low power, portable equipment capable of operating from a variety of power sources.

This article, then, is an attempt to provide basic application information on CMOS oscillator circuits as well as providing an overview of basic CMOS features and characteristics. As you will see, they are very versatile devices that are easy to use once you become accustomed to their peculiarities.

CMOS integrated logic circuits offer several distinct advantages over other logic families. Some of these advantages may be summarized in the following:

1. *High Noise Immunity*: To understand this characteristic, it will be necessary to refer to the transfer characteristic curve for a typical CMOS IC inverter. Fig. 1 shows this transfer characteristic, which is the relationship between the input and output voltages. Note that the output voltage is affected by a change in the input voltage only at the transfer point. The steepness of this curve also indicates that as the transfer point is reached, there is an abrupt change or a "toggling" of the output.

Usually, the transition voltage is specified to occur between 30% and 70% of the power supply voltage. Thus, for a 15 volt power supply, the input noise transient would have to exceed 4.5 volts for it to affect the output. This feature provides for very stable monostable multivibrator circuits where the CMOS device is used as a one shot trigger source.

2. *Low Power Requirements*: Almost everyone is now familiar with the low power consumption of CMOS devices. This feature is one of the primary considerations for using CMOS devices in digital watch circuits.

The CMOS family exhibits low power consumption due to the way the output transistors are connected — in series, so that power is consumed only during transistion states. All CMOS devices incorporate at least two MOS transistors in series — one p-channel and one n-channel. Consequently, only one transistor is turned on at a time and there is no direct path for current to flow. The only exception to this rule is during transition states, and then only for very short time periods. Fig. 2 is a diagram showing the output transistors.

Note that as the frequency of the oscillator circuit is increased, the conduction times also increase, so that power consumption is directly proportional to the operating frequency. Typical quiescent dissipation for an inverter, however, is less than 300 uW per package for a 10 volt supply (CD4009A).

3. *Wide Range of Power Supply Voltage*: Another fea-

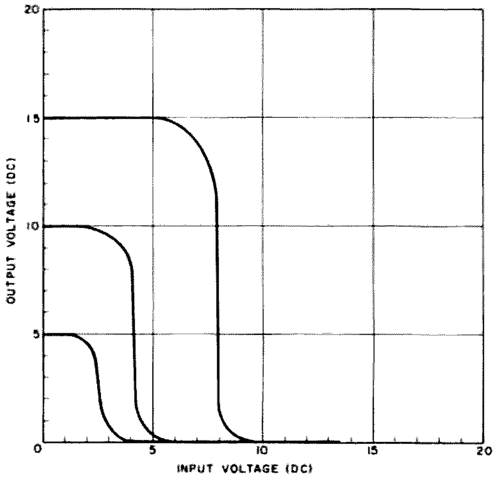

Fig. 1. Transfer characteristics for a typical CMOS inverter at 5V, 10V, and 15V.

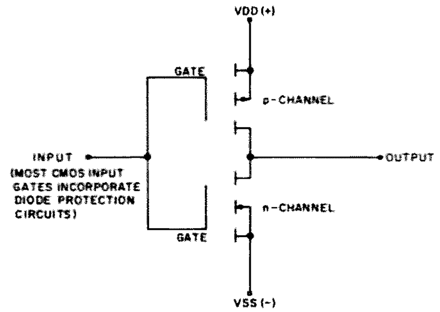

Fig. 2. Typical CMOS inverter stage (simplified). Except for short periods during switching of states, only one output transistor is on at a time. This results in extremely low power consumption.

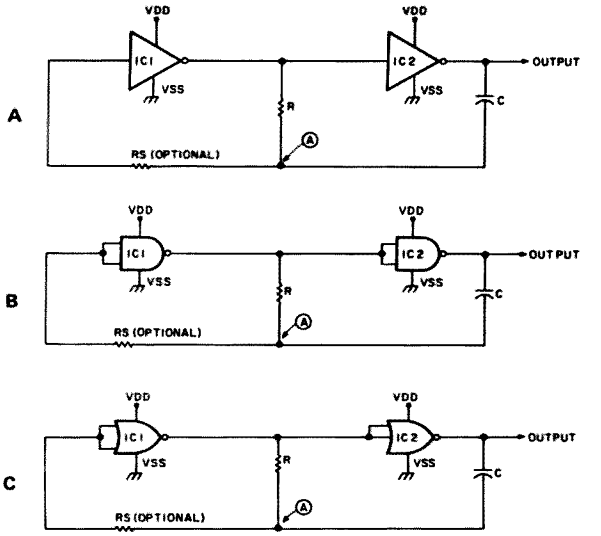

Fig. 3. Three typical CMOS astable multivibrator circuits. (a) CMOS inverter astable multivibrator. IC1, IC2 = 1/6 CD4069. (b) CMOS NAND astable multivibrator. IC1, IC2 = CD4011. (c) CMOS NOR astable multivibrator. IC1, IC2 = CD4001.

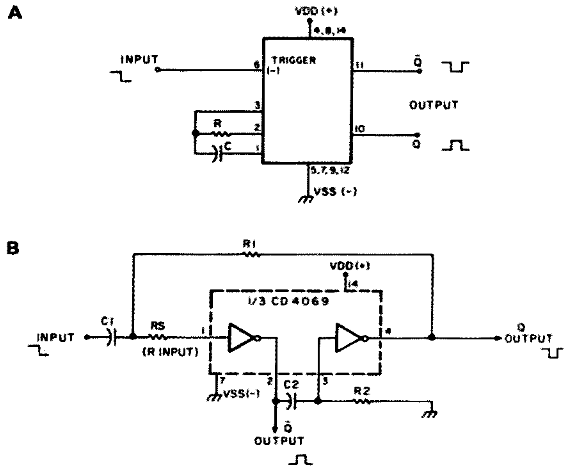

Fig. 4. Monostable multivibrator circuits for negative-going input pulses. (a) CD4047. (b) CD4069 (hex inverter).

ture that is unique to CMOS devices is the wide range of supply voltages over which they will perform satisfactorily. Typically, most manufacturers guarantee operation over a range of 3 volts to 15 volts. However, some versions will operate up to 18 volts. With this feature, it's not necessary to design well-regulated power supplies and, in most cases, batteries work just fine. Also, the voltage range makes CMOS devices ideal for automotive or mobile applications.

4. *Wide Temperature Range*: The usual package most hams or hobbyists will be working with is the dual-in-line plastic package (suffix AE or BE). This unit is suitable for a temperature range of -40°C to +85°C. The more expensive ceramic version (suffix AF or BF) will operate over a temperature range of -55°C to +125°C.

5. *High Input impedance*: The input gates of all CMOS devices have impedances on the order of 10^{12} Ohms. This results in extremely low input current requirements (typically ± 10 pA) and consequently very little loading on the input circuit. Another advantage resulting from this high input impedance is directly applicable to oscillator circuits. The high input impedance makes it possible to obtain large time constants without the use of large capacitors. This means that CMOS devices can provide cost and size reductions in most multivibrator circuits.

Before we get into some actual multivibrator applications, a word of caution is in order. Since an inverter functioning as an oscillator operates a considerable amount of time in the linear region of its transfer curve, some CMOS devices cannot withstand the high power dissipation. These devices include the CD4009A and CD4010A. Instead of using these devices, the CD4049 and CD4050 would make a better choice.

Astable Multivibrator Circuits

An astable multivibrator is basically an oscillator that generates a square wave output at a specific frequency. The frequency of the square wave may be determined by an RC circuit, crystal, or analog voltage.

Astable multivibrators may be constructed from a basic inverter IC or from NAND or NOR gates connected as inverters. Fig. 3 shows three basic types of astable RC multivibrators.

All CMOS gates have a built-in diode protection circuit to clamp large input voltages and prevent the gate from being destroyed. To minimize the effect of this input circuit on stability, a resistor (Rs) is connected from the timing circuit to the input of the first inverter. This, in effect, limits the current to the input gate.

In operation, the input of the first inverter is clamped at approximately Vdd or Vss, whichever is appropriate. At any particular instant, capacitor C will be charging or discharging through resistor R. When the capacitor is discharging, the voltage decays at point A until transfer occurs for inverter 1 and its output switches from zero level to the power supply voltage, causing the output of IC2 to switch from the power supply voltage to zero. When this occurs, capacitor C begins to charge. This continues until the voltage at point A builds to the transfer point. When this occurs, the output of IC1 switches to zero volts, causing the IC2 output to switch to the positive supply voltage. At this point, the cycle is ready to begin again.

The frequency of the square wave output will be dependent on the values chosen for R and C. Also, to limit current at the input gate of IC1, the rule of thumb is that Rs should be approximately twice the value of

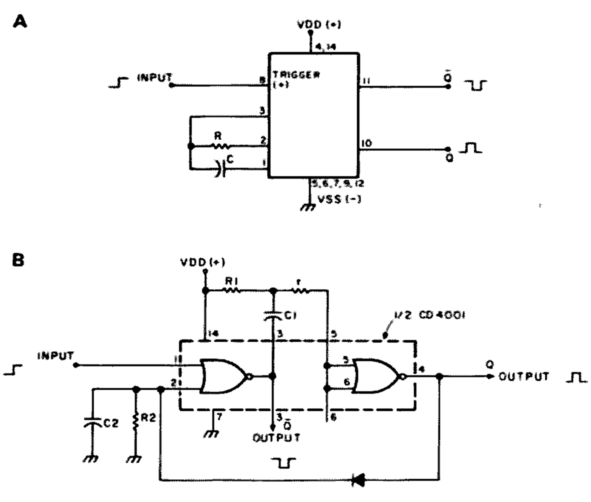

Fig. 5. Monostable multivibrator circuits for positive-going input pulses. (a) CD4047. (b) CD4001 two-input quad gate.

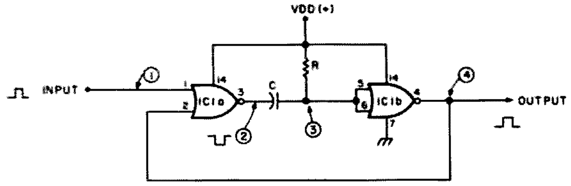

Fig. 6. Basic one-shot multivibrator circuit using two NOR gates. IC1a and IC1b = ½ CD4001.

resistor R.

Monostable Multivibrator Circuits

A monostable multivibrator is a logic circuit that generates, upon command, a single output pulse of set duration. It is commonly referred to as a "one-shot" multivibrator. There are monostable circuits that are triggered by a negative-going input pulse (Fig. 4), as well as circuits that are triggered by a positive-going pulse (Fig. 5). Both of these circuits may not be retriggered until they return to steady state conditions. Hence, they are often used to debounce mechanical switches in a variety of applications.

To understand how monostable multivibrators function, refer to the circuit shown in Fig. 6. This diagram shows two NOR gates from a quad CD4001 connected in series. This basic one-shot circuit operates with a single RC time constant. When a positive-going input pulse is applied to the input at 1, it causes the output of IC1a to go to ground potential (zero volts). This in effect grounds the input of IC1b until capacitor C charges up to the transfer level. During this timing period, the output of IC1b is at V+. When point 3 reaches the transfer level, the output of IC1b switches to zero, causing the input of IC1a to become zero. Assuming there is no input signal on the other input, the output of IC1a switches to V+ and the circuit is ready to be triggered again. It is important to note that this circuit, once triggered, is immune to further triggering (or noise) until the timing cycle is complete and the circuit is reset.

If the power source (V+) is greater than +5 volts, you may want to include a series resistor at IC1b to limit the input current at the gate.

CMOS Crystal Oscillators

CMOS devices make excellent and stable oscillators when a crystal is used as the frequency determining element. Fig. 7 shows several circuits for CMOS crystal oscillators using a variety of devices.

Generally, crystal oscillators using CMOS devices operate in the frequency range of 10 kHz up to a top limit around 10 MHz. For lower clock rates, the basic oscillator stage is connected to divider circuits until the correct clocking rate is achieved.

Voltage Controlled Oscillators

Previously, we discussed a type of oscillator whose frequency was determined by a fixed RC circuit. By changing the value of R (or C), the frequency of the oscillator will be varied proportionately.

A voltage controlled oscillator is merely a standard RC astable multivibrator in which the value of the resistor R is varied by a control voltage. Just how this is accomplished is illustrated in Fig. 8. "R" has been replaced by a semiconductor device whose resistance varies from 1k to 10k. These limits are determined by a parallel combination of R1 (10k) and the resistance of an n-channel device which varies from 1k ("on" state) to 10^9 Ohms ("off" state). The center frequency of the VCO may be determined by varying the value of capacitor C.

Phase Locked Loops

Using the VCO discussed above as the basic circuit, it's possible to build a phase locked loop (PLL) using CMOS devices. Suppose we could compare the output frequency of a VCO to a reference frequency and develop an error voltage with a magnitude proportional to the frequency deviation. If this error voltage was fed back to the input of the VCO, its output frequency could be corrected back to the reference frequency. In so doing, the two circuits would lock in phase at the reference frequency.

It is interesting to note that the CMOS family of devices has a phase locked loop element which is unique to the CMOS family – there is no TTL equivalent. This device is the CD4046 and a typical PLL circuit is shown in Fig. 9.

In this circuit, the minimum output frequency occurs when the input control voltage is at zero. When the input control voltage is at the power supply level, the output frequency is at a maximum.

Frequency Multipliers

In this application, CMOS devices may be used to build circuits that generate output signals having a frequency equal to a multiple of the input signal frequency.

An example of a multiply-by-two circuit is shown in Fig. 10. It's also possible to

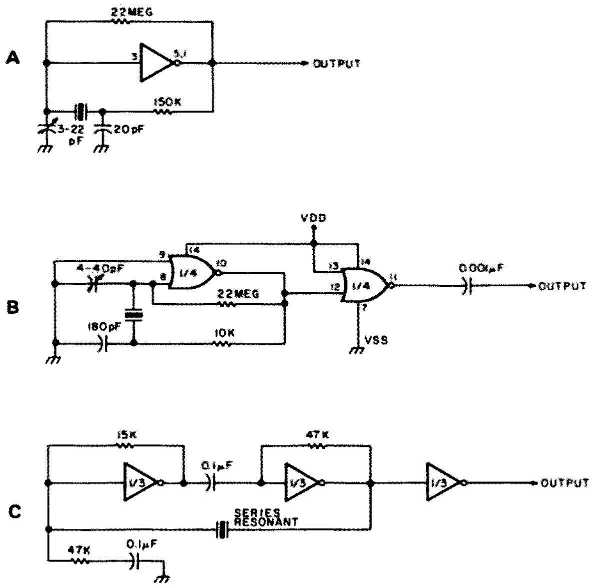

Fig. 7. CMOS crystal oscillators. (a) MC14007 or CD4007. Pin 7 – Vss. Pin 14 – Vdd. Note: Pins 5 and 1 must be connected together for proper operation. (b) CD4001. (c) CD4049.

build more sophisticated multiply-by-n circuits by using a PLL and a divide-by-n in the feedback circuit.

In the multiply-by-two circuit, two RC circuits are used with an inverter to produce negative pulses on one input of the NAND gate when the input goes positive. A second negative pulse occurs at the input of the other NAND gate when the input signal goes negative.

As with any two-input NAND gate, a negative pulse on *either* input gate causes the output to become positive. Hence, the output frequency will be twice the input frequency.

Additional Information

There are several sources of information available to you for further investigation of CMOS devices. The following publications will provide you with a wide range of reference information: "Understanding CMOS Integrated Circuits," R. Melen & H. Garland, (H.W. Sams); "COS/MOS Integrated Circuits," RCA Solid State; "MOS/CCD Data Book," Fairchild Semiconductor; "CMOS Integrated Circuits," National Semiconductor; "McMOS Handbook," Motorola.

In addition, the "Electronics Sourcebook" contains a handy index of industry application notes and publications relating to CMOS devices. It's available for $3.75 postpaid from Technical Publications, 1405 Richland Ave., Metairie, LA 70001.

I would be interested in hearing from readers who have unique applications for CMOS devices as described in this article. If there is enough response, there may be a follow-up article about CMOS devices in other applications. ■

A Dial for the FM-DX

-- in case the LEDs fail

Readers of *73* may be interested in a modification performed on my FM-DX. Recently I had one of the LEDs in the digital display go out on me, presenting the problem of guessing how to dial up frequencies.

While waiting for a new LED to arrive, I solved the guessing game by installing indexed knobs on the three selector switches. As the picture shows, with no LED display, it is now possible to dial up a frequency using only the knobs. This also helps when operating in direct sunlight.

The knobs used were obtained at Radio Shack (Cat. No. 274-413) and are numbered 0-9, exactly as needed for this application. The diameter of these knobs was too large, however, and required removal of approximately 1/8" from the outside edge. A little careful machining with a drill press and file corrected this problem.

Catalogs show other knobs available in smaller diameters which would be more suitable, but I had to act in haste for the immediate emergency. ■

Robot 400 Scan Converter Details

-- conventional TV as SSTV monitor

If you ask experienced SSTV operators what the major barrier to widespread acceptance of slow scan television might be, you will almost always get the same answer – the display system! Most amateurs are now familiar with the major aspects of the slow scan system first developed by Copthorne MacDonald in the late 1950s. SSTV involves the transmission of a 128 line picture which is transmitted over a period of approximately 8 seconds. This extended frame time, coupled with the modest number of scanning lines, results in a picture format that is compatible with voice bandwidth signals and thus can be transmitted on the high frequency bands using normal SSB phone equipment. At first glance one might assume that the 128 line picture with its limited resolution might be a problem, but most amateurs on seeing a photograph of an SSTV image are quite impressed by the quality of the pictures. The real problem arises when a convert sees his first SSTV demonstration. In order to view a picture that requires 8 seconds for transmission, a conventional monitor must employ a cathode ray tube with a long persistence phosphor, usually a P7 CRT. The long persistence component of this phosphor is not very bright and the pictures can only be viewed effectively under subdued light, hardly the conditions that exist for most demonstrations. The phosphor is quite bright where the screen is actually being scanned, but fades rather rapidly, resulting in a pronounced "window shade" effect as the picture is scanned from top to bottom. Another disturbing feature is that the phosphor is yellow, resulting in black and yellow images rather than the familiar black and white of monochrome TV.

Slow scan experimenters have long recognized that a conventional TV set represents a very effective display system if there were some means available to convert the slow scan image into a conventional TV picture. This conversion process is known as *scan conversion.* In theory, scan conversion requires some means of storing the incoming SSTV picture and then repeatedly reading out the stored video information at scanning rates compatible with conventional television display. The two most promising approaches to this problem to date have been *analog* scan conversion and *digital* scan conversion, and amateurs have pioneered in the development of each. The analog process involves the storage of the picture by means of a vidicon-like tube with a special silicon target. The picture is painted electronically on the target by scanning at the SSTV rates and, once it is impressed on the target of the tube, it is retained for a considerable period. The charge distribution resulting from the SSTV image is then scanned repeatedly at fast scan rates to produce a conventional TV video signal. The first SSTV analog scan converter was produced by W9NTP and displayed at Dayton several years ago. W2DD and a number of other amateurs successfully experimented with modifications of commercial analog scan converters with some success, and Robot Research of San Diego eventually introduced their Model 300 analog scan converter. This was an effective unit that could not only

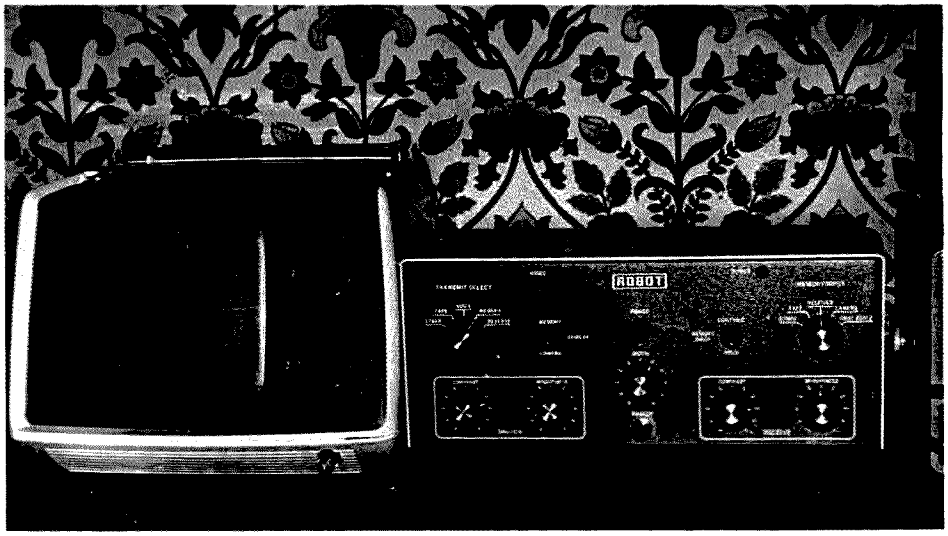

Fig. 1. The Robot Model 400 digital scan converter and the Sony TV-770 which has been modified to serve as a video monitor. A set of this size is ideal for viewing at the distances encountered in most installations. The 400 is very compact and generates essentially no heat, allowing it to be placed anywhere that is convenient.

provide fast scan display of an SSTV picture, but it was also capable of storing a single frame from a fast scan closed circuit TV (CCTV) camera that could then be transmitted in the SSTV format. There were several major restraints to both amateur and commercial efforts in the analog area. The first was cost, due almost entirely to the expense of the special storage tube. Secondly, because such converters are analog devices, the scan converters had a great many interacting level controls that took some practice to use effectively. Finally, the image storage in the tube is not perfect, and the image begins to fade after 10-20 minutes of display. Although the retention factor is not important in some applications, it does limit the device.

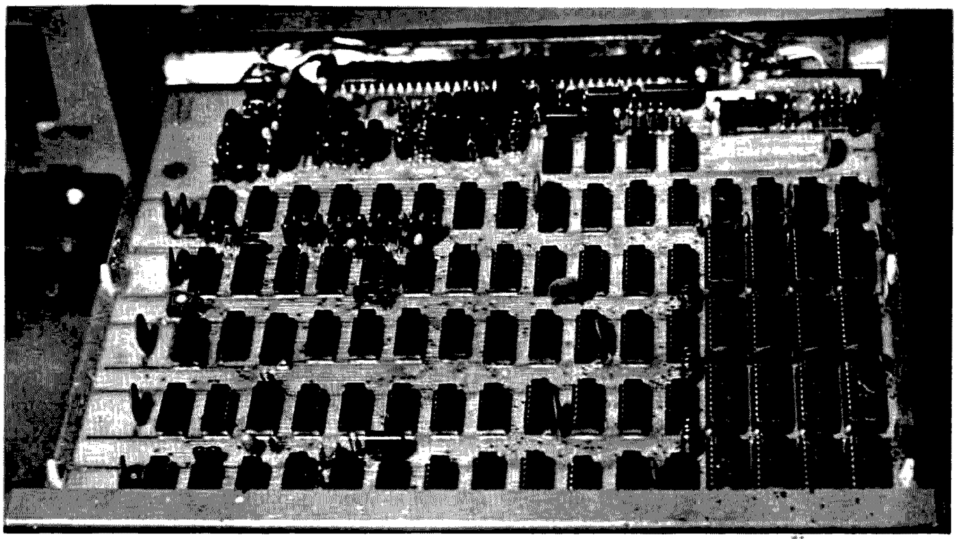

Fig. 2. Internal view of the Model 400 with the top cover removed. Virtually all of the active circuitry is confined to the single large plug-in circuit board. The 16 large ICs in the lower right are the 4K RAM chips that comprise the main memory. All of those other little packages are required to address the memory, perform A/D and D/A conversions, and process both SSTV and fast scan video. Cabinet space below the circuit board is devoted to power supply components. Controls are mounted on the front panel with I/O jacks on the rear panel. The controls and jacks have few discrete components associated with them, and those which are present are used mostly for rf bypassing, resulting in excellent resistance to RFI. Note that sockets are employed for all ICs, easing any problems with servicing and making it relatively easy to experiment with the unit.

The other alternative — digital scan conversion — appeared to offer the greatest long-term promise, but development was impeded by the sheer complexity of the circuitry required. One of the major problems was the sheer size of the digital memory. A 128 line SSTV picture consists of 128 x 128 picture elements or *pixels* — a grand total of 16,384. The solid state memory (in the form of shift registers or later RAM) would have to have a capacity of at least 16,384 bits to store an SSTV picture without loss of resolution. Digital storage, however, is in the form of low or high data bits so that even a 16K bit memory could only store a picture of either white or black pixels with no intermediate gray scale values! Storing gray scale values requires still more memory. Too few gray scale shades and the picture will have a crude paint by numbers appearance known as *video contouring.* Video contouring is essentially unnoticeable on a standard TV display if 32 gray shades are employed, but the memory requirements are excessive. 16 gray scale shades (requiring four bits of memory for coding for each pixel) appears to be the best compromise between memory size and picture fidelity. The memory must therefore consist of 16,384 x 4 bits — a total of 65,536 bits. If the memory is in the form of 1024 bit shift registers, as it is in most current amateur designs, a total of 64 shift register chips are required for the main memory alone. To this must be added the SSTV signal processing circuits, analog to digital conversion (A/D) to convert the analog video to a digital format, slow scan clocks, clocks to circulate the main memory, fast scan clocks and sync circuits, the D/A converters to convert the digital video back to analog form, and finally a series of input and output line buffers (more memory) to clock the video in and out of the main memory. Needless to say, a digital scan converter is a complex project. Beginning just a few years ago, the design and building efforts of WØLMD, W9NTP, and WB9LVI produced working scan converters that were displayed at the annual Dayton extravaganza. Anyone who viewed the clear, non-fading, black and white images displayed by these units could not help but realize that digital scan conversion of SSTV pictures was the wave of the future. Other amateurs worked up PC board layouts for such projects, the LVI unit was described in *QST*[1] and, despite the complexity of undertaking such projects, the home brew SSTV exhibit at Dayton last spring consisted almost entirely of digital scan conversion units. What was needed to bring such technology from the experimenters to the average ham shack was the introduction of comparable commercial equipment. Robot Research, true to its position as a pioneer in the area of commercial SSTV equipment, has done just that with the recent introduction of their Model 400 digital scan converter. One of the early model 400s was obtained to perform an evaluation of the unit's potential, and what follows is the result of that evaluation.

The Model 400, in conjunction with a closed circuit TV monitor or, in some cases, a modified TV set, and a standard CCTV camera, will perform virtually all of the operations required for working two-way slow scan TV. On the display side, it will take an SSTV signal from *any* source — the receiver, tape recorder, SSTV camera, flying spot scanner, or keyboard — and display the picture on a TV monitor. With the flick of a switch you can have each new picture replace the previous one, bit by bit as it comes in, or you can freeze the picture in memory and view it as long as power is applied to the scan converter. Recordings of incoming SSTV pictures can be made directly from the source or from the digital information stored in the memory. A very handy feature of the 400 is its ability to provide "instant replay" of pictures received

over the air. If a received picture is held in memory, you can transmit from the memory and thus show the station at the other end what a representative frame looked like at your end. This is particularly useful in critiquing pictures as it is possible to show the other operator that contrast, lighting, composition, or some other factor requires improvement.

The 400 also functions in generating SSTV pictures from a fast scan CCTV camera or other video source. A single frame of fast scan video can be "snatched" and stored in the 400's memory and read out in the SSTV format for transmission and/or recording. Frame snatch can be initiated manually at any time desired or it can occur automatically at the beginning of each SSTV frame. Since a single fast scan frame, occurring over a time interval of 1/60 of a second, is all that is required, motion no longer distorts the image and the subject need not remain motionless during the SSTV frame interval. The 400 permits real time viewing of the fast scan video in its digitized form so that there is no doubt as to how the picture will look when snatched. Levels are set up in the 400 so that the picture as viewed on the monitor is exactly how it will appear at the other end. All frames obtained using the snatch function have a four step gray scale inserted in the last couple of lines in the frame. This is an extremely useful feature as it provides you with a constant contrast reference when setting up the picture as well as providing the operator at the other end with an unambiguous reference against which to judge tuning, his contrast and brightness adjustments, and your video "swing."

The 400 also incorporates a precision 4 step digital gray scale to assist in setting the brightness and contrast on received pictures and providing a comparison scale for setting up the same values in pictures to be transmitted. In short, it would seem that the 400 can do just about anything. Let's look briefly at the physical and electrical characteristics of the unit and then see how this performance potential is actually realized in practice.

Physical Description

The 400 arrives beautifully packed and is unlikely to suffer damage in shipment. It weighs 12 pounds and is packaged in a rugged two-piece aluminum cabinet measuring 12.5 inches wide, 6 inches high, and 11.75 inches deep. The unit is finished in the two-tone gray that is characteristic of the Robot equipment line. A front panel view of the 400 is shown in Fig. 1. All of the active circuitry (including the 16 4K RAM chips for the main memory, 77 other ICs, 19 transistors, and an array of discrete components) is contained on a single magnificent circuit board (Fig. 2). The rest of the cabinet simply serves to hold the power supply, front panel controls, the I/O jacks on the rear apron, and a few components associated with the controls. The main circuit board is a work of art and all of the components and wiring are of the highest quality.

The front panel control layout is well engineered with a largely functional grouping of controls. Power is controlled by a single central toggle switch with an LED indicator. The unit can be ordered to operate on 115 or 230 V ac at 50 or 60 Hz. Line voltage and frequency must be specified when ordering since there is some change in clocking and associated circuits when operated at 60 Hz as opposed to 50 Hz. Input to the main memory for display is selected by a front panel rotary switch (MEMORY INPUT). Options include GRAY SCALE, CAMERA (fast scan CCTV), RECEIVER, TAPE, and OTHER (SSTV sources such as cameras, flying spot scanners, keyboards, or alternate receivers or recorders). A MEMORY INPUT toggle switch permits continuous display of new pictures or freezing the existing picture in memory. BRIGHTNESS and CONTRAST controls are provided to adjust these values for SSTV display. Another control (WIDTH) adjusts the internal oscillator to accommodate pictures from 60 Hz and 50 Hz sources.

The remaining controls function on the transmit side of the SSTV operations. A TRANSMIT SELECT rotary switch controls the signals routed to the transmitter and tape recorder. These options include VOICE (station microphone audio in transmit and unprocessed audio from the receiver when recording), MEMORY (the contents of the main memory), REVERSE (a black to white reversal of the image in the memory which is handy for special effects), TAPE (pictures previously recorded on tape), and OTHER (other SSTV sources which can be transmitted or recorded without going through the 400s digital memory). A DISPLAY toggle switch permits real time viewing of the digitized output of the fast scan camera or viewing of the memory contents. A SNATCH push-button permits manual updating of the fast scan camera image in memory. The fast scan snatch function has its own front panel CONTRAST and BRIGHTNESS controls so that good video swing can be obtained from cameras whose fast scan output may be of marginal quality.

The rear panel has the ac cord and circuit breaker plus the multitude of jacks required for interconnecting the 400 with the other equipment. Two of the jacks are BNCs (input from the CCTV camera and output to the video monitor) and Robot supplies a 5 foot length of coax with BNCs on each end for connection between the 400 and the monitor. Two jacks are 3 conductor phone jacks, one of which is for the station microphone and the other for a cable between the 400 and the audio input to the transmitter. Robot supplies a cable for the latter and you simply have to equip your microphone with a 3 conductor ¼" plug. Normal microphone PTT functions are looped through the 400. The microphone provides the audio to the transmitter in the VOICE position of the TRANSMIT SELECT switch while other positions select video sources as described previously. A front panel LED indicator comes on when video has been selected and a gain control on the rear apron lets you set the video output from the 400 to a level compatible with your transmitter audio input, eliminating the need to alter the transmitter audio gain. This gain control only functions when the 400 is generating the SSTV signal from its memory. Outside sources such as tape or other SSTV cameras must have their levels adjusted at the source. All of the other jacks on the rear apron are standard phono jacks for the receiver output, input from other sources, and input and output from the tape recorders). Robot supplies a cable for connection to the receiver and all other interconnections can be made with suitable shielded hi-fi cables.

Circuit Description

There is no way that a few well-chosen words or paragraphs are going to do justice to a complex circuit such as the 400 or any other scan converter for that matter. All I will attempt here is to hit some of the high points in describing the operation of the unit. The heart of the 400 is its digital memory. The memory is composed of 16 UPD411D random access memory (RAM) chips, each with a capacity of 4092 bits

* The Robot 400 Converter can be connected to the antenna terminal of a home TV set by means of the Robot RF Adapter Kit option for $25.

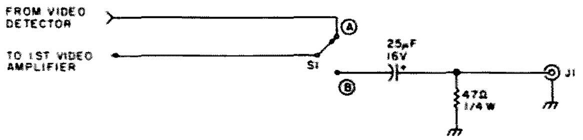

Fig. 3. Modification of a small solid state TV set for use as a video monitor. The set must be transformer operated with a grounded chassis to avoid a shock hazard and possible damage to the 400. J1 is a BNC jack and S1 is an SPDT toggle switch. Position A is for normal TV viewing, while in B the set functions as a video monitor. Similar conversions can be implemented in a variety of sets. The one I use is a Sony TV-770. In the 770, the line from the detector to the first video amp is a small piece of gray coax with a brown stripe. The coax is disconnected from the video board and soldered to the switch contacts (A). A small piece of subminiature coax is routed from the common switch lug back to the disconnect point on the video board. In converting the 770 or any other set, you should obtain a schematic or, better yet, a Sams Photo-facts booklet for the set prior to surgery. All of the SSTV pictures for this article were taken using the TV-770 and it does an excellent job.

(4K). These are dynamic memories and hence require a refresh cycle to retain their stored data. The 400 circuitry is set up so that the refresh cycling is provided in conjunction with the fast scan read operation which is going on continuously as long as power is applied to the 400.

Processing of SSTV signals is fairly conventional with op amps employed as limiters and active filters to provide the video waveform and sync signals to appropriate Schmitt triggers interfacing the SSTV sync signals to system logic levels. Incoming SSTV clocking is derived from a free running oscillator whose frequency is set by the WIDTH control on the front panel. The oscillator is triggered by the horizontal sync pulses derived from the incoming SSTV signal, thus locking the clock to the incoming video format. The A/D converter is composed of a series of 711 voltage comparators. The use of 1% resistors in the A/D circuits assures a precise A/D conversion. Initial A/D conversion is to gray code with onboard conversion from gray code to binary.

Fast scan clocking and sync and all internal slow scan clocking from memory is referenced to an onboard crystal oscillator assuring rock stable clocking at all points in the system. The RAM memory is multiplexed in the 400 to achieve the speed required for fast scan display. The D/A conversion is accomplished with a 7486 and a series of 1% weighting resistors with several discrete transistors providing the interface to the external video monitor.

When snatching video from a fast scan source, the fast scan sync pulses from the source lock up an oscillator which serves as the reference for clocking the fast scan frame into memory. Readout from memory in the slow scan format is achieved with a custom VCO chip factory set for the 1200 Hz sync and 1500 and 2300 Hz black and white levels. Active devices are used throughout the 400 for digital and analog switching functions, thus vastly simplifying the interconnections between the board and the 400 controls and I/O ports.

The 400 manual provides a complete schematic and quite a detailed circuit description, and your ability to understand the inner workings of the beast should largely be limited only by your effort in studying the manual. Should you want to do a little digital design work yourself, the 400 is a marvelous store of interesting design approaches.

Performance

Hooking up the 400 to perform all of its tricks will require a video monitor and a standard CCTV camera. Suitable video monitors can be purchased from Robot or CCTV outlets and you can expect to pay between $250 and $300 for a suitable monitor going this route. Excellent monitors can often be obtained at very good prices from computer stores and at the larger hamfests. It is also possible to modify a standard TV set for use as a monitor but *you must not use a set with a hot chassis.* Such a set can be dangerous to your health and, what is worse, will almost certainly damage the 400. The set shown in Fig. 1 is a Sony TV-770 converted to video monitor service as shown in Fig. 3. A small screen monitor is a must and you should not consider a screen size larger than 9" unless you plan to use it strictly for large group demonstrations. Screen sizes between 5 and 8" are ideal for normal viewing distances and the TV-770 is just about ideal and costs about $140 maximum. If you absolutely must use a set with a *hot* chassis, then you should go the rf route, converting the 400 video output to an rf signal for viewing on an unused VHF channel. Robot markets a board ($25) for this purpose. The rf route is the only safe approach to using a hot chassis set since the manufacturers have taken great pains to isolate the antenna terminals from the dc circuitry. Personally, I would only resort to rf display for occasional use in large demonstrations where it is feasible to use any large screen set that might be available.

CCTV cameras can also be purchased from Robot, CCTV outlets, or at the larger hamfests. As noted later, almost any camera with standard video (not rf) output can be used. Bargains in used cameras can usually be obtained from CCTV outlets, security operations, or community TV companies.

An experienced slow scanner can have the 400 displaying pictures within ten minutes after the package arrives at the door, but I would suggest that you spend some time with the instruction manual as it has an excellent description of the function of the various controls and should answer all of your questions about interconnection with your own equipment. In terms of all of its functions, the unit I received worked right out of the box, but I did notice an apparent problem with a lack of sensitivity at the SSTV inputs (receiver, tape, and SSTV sources). This was particularly noticeable when the level from external SSTV sources was reduced for proper transmitter operation, for at the proper output levels, the 400 would not lock up reliably. The specifications indicated that the SSTV inputs should limit with a signal level of 20 mV, but a quick check showed that this was not the case. A call to Robot revealed that this had been a problem with some of their first production units and that current production models had some resistor changes that eliminated the problem. Substitution of the new values immediately brought my unit up to specs and it is unlikely to be a problem with any 400s other than the first sets that left the factory.

The 400 was very easy to set up for proper video display and has performed flawlessly. Noise immunity is the equal of the best home brew circuits I have used, and the unit does an excellent job even under current band conditions. The major feature I felt was lacking was a tuning indicator to assure proper carrier insertion when tuning the HF sideband gear. If the pictures you are receiving have normal contrast, tuning

Fig. 4. A collection of miscellaneous SSTV pictures logged on 20 meters and displayed on the Robot 400. Only a simple dipole was used for the antenna system and, despite the current state of the band, the 400 delivered excellent pictures. Picture quality in terms of sharpness and contrast is limited only by the care with which pictures are set up at the transmitting end. If you are willing to alter the receive BRIGHTNESS and CONTRAST controls from their proper settings, even pictures of poor quality can be improved considerably. I tend not to alter these controls once they are properly set, as I want to be constantly in a position to realistically evaluate picture quality, and the replay (from the 400 memory) of a station's pictures can do wonders in getting the operator at the other end to set the pictures up more carefully!

is quite easy — you simply tune for maximum contrast and you will be right on the money. Unfortunately, there are still too many operators who are grinding out pictures that are low in contrast, and these can result in errors in tuning as you attempt to optimize video display. An LED tuning indicator can easily be added to the 400 (see the *73 SSTV Handbook* for circuit possibilities) if you desire. The lack of a tuning indicator does not really detract from the 400's performance — I just like the convenience they provide. A number of representative pictures are included to show you what can be expected under normal band conditions.

Tape display is extremely reliable even with cassette recorders. Despite Robot's caution to use recorders with good wow and flutter specifications, a number of 10 year old tapes — recorded on a battery operated reel-to-reel recorder — actually displayed quite nicely. Given the over-the-air performance, one might expect that display of local SSTV sources would present no problems, and this is definitely the case. A variety of SSTV cameras, flying spot scanners, and an SSTV keyboard were tried with excellent results being obtained in all cases.

Experienced slow scanners may be curious to know how the 400 shapes up in the contouring department since it does not employ line averaging or psuedo-random noise techniques. The key here is the use of a small screen monitor. With the proper monitor display, contouring has little or no subjective impact when the pictures have a normal contrast range. Contouring will always be visible with 16 gray scale shades if you take the trouble to look for it, but none of the people who have seen pictures on my 400 have even mentioned the effect. Contouring is more easily noticed if there are extensive areas of the picture with little or no detail, such as the background of an ID sign that is not evenly lighted, or in pictures with too little contrast. In the latter case, you are attempting to display a picture using too few gray scale steps and the effect is that of using a system with fewer gray shades.

One operational convenience of the 400 that I did not anticipate was the case in making demonstration tapes. I usually record pictures off the air using a cassette tape deck. Such tapes typically have many frames marred by QRM and intervals of conversation. When such a tape is reviewed, you can freeze a particularly good frame in the memory, remove the tape from the machine, and substitute your demo cassette. You can then record two or three frames from the 400 memory, replace the tape again, and begin looking for other good frames. A single small cassette can thus contain the best pictures from a large number of tapes, result-

ing in an excellent record of your contacts as well as a good tape to play at radio clubs or hamfests to generate a little interest in SSTV. Many tape decks do not incorporate automatic level control, and these are often tedious to use since you have to ride the gain control to keep a reasonably constant signal level when recording pictures off the air. This problem can be eliminated if the transmit select switch is placed in the memory position during recording. You are thus recording from the 400 memory and the signal will have a constant amplitude regardless of the input variations in the incoming SSTV signal. The only disadvantage of this technique is that you do not preserve the audio commentary. If the voice signal is desirable, you can simply switch the transmit select to voice when pictures are not coming in, but you will have to ride the gain!

The 400 does an equally good job in terms of all of its transmit functions as well. In common with past Robot equipment, the 400 handles the interconnection of the tape recorder and other SSTV signal sources to the transmitter with the ability to select either voice or a video source. Where it really shines, however, is in frame grabbing from fast scan sources such as a CCTV camera. With the display switch in the camera position, you view the fast scan picture in real time, but in its digitized form. The brightness and contrast controls for the snatch function let you compensate quite nicely for poorer than average subjects or flat camera output. The signal you see is precisely what will be stored in memory, so setup is no problem. With the memory input toggle switch in the continuous position, a new fast scan frame is snatched at the start of each SSTV frame. In the hold position, frame snatch is manually controlled with a front panel pushbutton. This is particularly nice if the camera is in an inconvenient position as you can face the camera, leer, and press the button, and then return to scratching or whatever else you do when the camera is not "live." A variety of cameras were used with the 400, ranging from some excellent new cameras with built-in viewfinders to an old Dage and several ancient home brew cameras. If you take the trouble to bring the broadcast video out of a TV set, you can also frame grab from that source. Broadcast video is excellent for test setups and demonstrations since it invariably has excellent resolution and contrast, but it is questionable whether you should transmit it on the air. I have seen quite a bit of snatched broadcast material on the air in the last few weeks, but it is worth noting that technically the practice is illegal since it involves the relay of material from the broadcast service via the amateur service. In any case, the material from soaps or afternoon game shows hardly raises the quality of 20 meter operations! The 400 will also frame grab nicely from a video tape recorder if you are lucky enough to have one of those goodies to play with. The frame grab capability of the 400 is simply so convenient that I will gradually be phasing much of my slide pickup and special effects cameras from SSTV to fast scan format, probably with a common sync source so that all can be tied in effectively with my fast scan operations on 440 MHz. The 400 has some interesting possibilities here since fast scan video from 440 can be frame grabbed and relayed via SSTV on 2 meters to stations that are outside of the normal ATV range in our area.

Summary

The components, workmanship, and performance of the 400 are simply first rate, and it is my own personal opinion that it represents the finest piece of commercial SSTV equipment on the market today. You can build a somewhat more versatile scan converter than the 400 and you would probably be able to do it for somewhat less than the $695 price tag of the Robot gear. Such an effort, however, would be a major project – probably one of the most complex projects that amateurs can undertake these days – and a careful evaluation would be required to determine if the small margin in performance that you might obtain would be worth the effort. The 400 is an excellent package at a good price for the value received. Its performance is such that I have no plans to put together a conventional scan converter for SSTV. I am in the process of adding additional memory and video circuits to accommodate real time color display, but any attempt to duplicate the features of the 400 itself is simply not worth the effort unless you enjoy building for its own sake.

Once you have used a digital scan converter, you will simply not be satisfied with a conventional monitor. Digital scan conversion is going to be responsible for another burst of growth in SSTV and a great deal of that potential growth will be chalked up courtesy of Robot and their 400. The unit is well-engineered and can be expected to perform well in the hands of a neophyte or an experienced operator. By all means seek one out for a demonstration – it will be worth the effort. ■

Bounceless TT Decoder

-- a single chip does it!

Do you remember the first time you went to the doctor and your mother told you that it wasn't going to hurt? Well, that trick only worked once, didn't it? I had much the same feeling the first time I tried to interface some TTL logic to the outputs of 567 decoders. Nobody told me that those nice decoders take several milliseconds to stabilize and, as we all know, TTL will count each and every little glitch just as if it were the real thing.

So, how do you debounce seven 567s without building some kind of one-shot or flip-flop for each one? Easy, especially if you have a Motorola CMOS data book. Look in it for an MC14490 and you will discover that it is a hex contact debouncer. How about that — 6 debouncers in one chip! Fantastic. How does it work? The same — fantastic!

Fig. 1 is the schematic of a circuit I built for our repeater. The 567s go directly into TTL gates to generate 12 data lines, 0-9, * and #. The gates faithfully transmit all the glitches supplied by the decoders. Reviewing the operation of the 14490s (Figs. 2 and 3) shows that basically all it does is wait until the signal on its input has been stable for four clock periods before the output will change to be the same as an input. Another handy feature is that by putting a single capacitor between two pins, a clock oscillator is formed. This same oscillator can be used to clock several chips. Interfacing the inputs of an MC14490 to a switch or TTL output is easy because pull-up resistors are included right on the chip. This means unused inputs can be left open, unlike normal CMOS inputs. But that is not all. Each output of a 14490 is capable of driving one TTL load. In our system, we decided that a 20 ms delay was desirable as it would eliminate all glitches from the 567s and tend to eliminate false noise decoding. The 0.01 capacitor results in an oscillator frequency of approximately 200 Hz, which gives four clock pulses every 20 ms.

The MC14050s are included to give enough current to drive the subsequent TTL logic used to decode various numbers and sequences we don't want dialed by our autopatch.

So, armed with MC14490s, no one should get stung by 567s, switches, or anything else that generates similar TTL-eating glitches. ■

Hams Profit From CB

-- how to set up a service center

David F. Norman
622 W. Sunset Blvd.
Fort Walton Beach FL 32548

Okay, most of the communicating community agrees – if somewhat grudgingly – that Citizens Band has a place in the scheme of things and even serves its user quite well at times. What most non-CB users and new CB users don't know is that there is a definite shortage of qualified CB technicians – and the shortage gets more acute each day. This is not to say that there aren't a lot of would-be CB repairmen. There are. The shortage is of *licensed* qualified technicians.

Under current FCC Rules and Regulations, only the holders of First or Second Class Radiotelephone operator's licenses can make repairs which can affect the legal operation of CB transceivers. That license isn't all that easy to get, either.

While there is no code test required for commercial phone tickets, there is a very stiff testing procedure. In order to qualify for a Third Class license – little more than a glorified Restricted Operator's Permit – elements I and II must be passed with a score of 70 or better. That is duck soup. These two elements are only to check the applicant's familiarity with basic FCC rules and proper operating procedures. Unfortunately, a Third Class license does not entitle the holder to do anything other than *operate* certain classes of radios – which are not germane to this article.

In order to qualify for a Second Class license, element III must be passed in addition to elements I and II. This is where it gets binding.

Element III is 2 to 4 hours of the hardest multiple choice questions that you can imagine. The closest parallel to it in amateur service is the Extra Class exam. The applicant who goes to the nearest FCC office had damn well better be prepared for element III or he is going to find himself winning only a Third (not much of a consolation prize) and facing a 60 day wait before he gets to try again.

If, however, he feels confident and really well prepared, he can add another buck and take element IV as well. The test applicant who passes elements I through IV, inclusive, gets to have his name typed on a beautiful, suitable-for-framing, First Class Radiotelephone operator's license (Fig. 1). Actually, element III is the hard one. Element IV only checks the applicant a little more closely in areas mostly pertaining to commercial broadcast stations.

For a couple more dollars, the passing applicant gets a wallet-sized verification card which attests to his having passed the necessary tests.

If you only want to work on non-commerical transmitters – CB, marine, land mobile, etc. – or smaller broadcast stations, a Second Class license is all that is required. However, there is a certain satisfaction in being "First Class" even if you never intend to exercise the additional privileges. And it just might happen that one of the local radio stations needs a part-time chief engineer. For an extra dollar, there is nothing to lose by trying for it.

If an amateur is pretty well up on his theory – General Class or higher – learning the extra knowledge required to pass the commercial tests will be a simple matter. The only additional materials that a commercial aspirant will need to borrow or buy are study guides or outlines for elements I through IV. Many local libraries have such volumes – which are published by TAB, Sams, Hayden, and others – on the shelves to lend. If your library doesn't have one or the one it has is several years old, either check in a larger bookstore or newsstand or watch for ads in electronics publications such as *73*.

The study guides that you used for brushing up on theory before taking the General test and the *ARRL Radio Amateur's Handbook* are excellent for taking a different approach on a point which gives you trouble. For more than one electronics hobbyist, that First or Second Class ticket has been the passport into a whole new career. If the holder of a commercial license has any ability at all to troubleshoot and repair electronic equipment, he can always make a living at it. Maybe he will have to move from where he is, and maybe he won't always do just what he wants at the pay he feels that he deserves, but he will always eat.

Attitude is Important

Just because a person has a crisp new First or Second ticket on his wall doesn't mean that those "chicken banders" are going to beat a path to his door. He is going to have to let them know that he is interested in seeing that their equipment is working properly and that, as an amateur, he doesn't look down on them. As is the case in amateur radio, operators of CB equipment have many different vocations and often are very, very good in their particular fields. A case in point is a recently overheard

QSO on 40 meters where the ham was remarking that the friend in the shack with him had a trenching machine and was digging the footings for the tower and guy anchors for the tower which the ham was in the process of building. That is the kind of friend to have. Dig?

As CBers learn of a new repair service in the area, word travels quickly. The bad word travels fastest. The good word travels farthest.

In almost every town, there is at least one CB dealer selling CB gear without having any real service department. A polite call on him to ask for his business and assure him that you are not interested in competing with him may be the beginning of a profitable relationship. The current rash of discounting takes a lot of profit out of the selling part of the business, anyway — you can make more on an installation than he does on the sale.

Taking all of your business from various dealers has at least one real advantage. If you deal strictly with dealers, you spend little time just talking to retain customers. On the other hand, the dealers may not provide you with as much business as you would like to have.

If the latter is the case, you should spend a few bucks taking out ads in CB club papers or local newspapers. If you plan your ads carefully and schedule them often enough to keep your service in the eyes of those you wish to serve, a few dollars will do a lot of good.

One fringe benefit of dealing directly with your customers rather than through dealers is the additional exposure that you can give amateur radio. (It's also a good way to move that older gear that you wish to replace with more sophisticated equipment.) Each year thousands of CBers will decide to get further into radio. What better way to spark this interest than offering to give demonstrations — you can even schedule a group to watch — some slow weekend?

A positive, non-condescending attitude will go a long way towards making friends and regular customers among local CBers.

Equipping Your Shop

If you intend to do any large amount of CB repairs, you will need to have some kind of shop. The shop can be your shack, if space and the XYL permit. However, a garage or small outbuilding is much better.

If you have a shop isolated as much as possible from the house, you have a more peaceful atmosphere in which to work; your customers won't be as likely to disturb your family or vice versa. If space at home doesn't permit a shop or zoning restrictions preclude it, you have at least two alternatives.

In most areas, there are small shop spaces for rent for 50 to 100 dollars per month. The drawback is that the locations are usually less than choice. If you are not geared for walk-in trade and keep erratic hours, this can be an advantage, especially if dealers provide the bulk of your business.

Another possibility is that one of your dealers may have a small back room that he will let you use. This is a little sticky, though, if you are doing work for more than one dealer. In any event, these are just ideas. If you have a friend who wants to work with you, he may have another alternative.

If you are really an active experimenter, you may already have much of the test equipment that you will need for CB service. Even if you have to start from scratch, you can do it for less than you might think. A lot depends on your resourcefulness. A successful dealer really hungry for service just might be willing to help you acquire what you need.

What do you really need for CB service?

Actually, $5000 will just about make it — plus parts inventory. However, let's assume that you *don't* have $5000 to invest in service equipment at this stage of the game.

Frequency Measuring Equipment

After the small tools and diddlesticks, soldering irons and wrenches, screwdrivers and drills, the first item to acquire is some device for measuring frequency. A Cushman or H-P or Lampkin would be nice, but none of these is a necessity. Among others, Heath makes several counters which work just fine for CB.

An older heterodyne frequency meter can also be used. All that is required is that transmitters tested meet or exceed FCC requirements. At CB frequencies, the tolerance is plus or minus 50 parts per million. However, only a poor technician or one faced with an unusual situation would ever pass a piece of CB equipment which was barely within the law. Most modern CB transceivers are selective enough now that a station anywhere close to the legal limit would sound distorted and range would suffer.

Signal Generator

Unfortunately, many small shops try to cut corners with signal generating equipment. When this is the case, the technician spends much longer than he should tuning a receiver. Rock-solid signal generating equipment capable of attenuation to below one

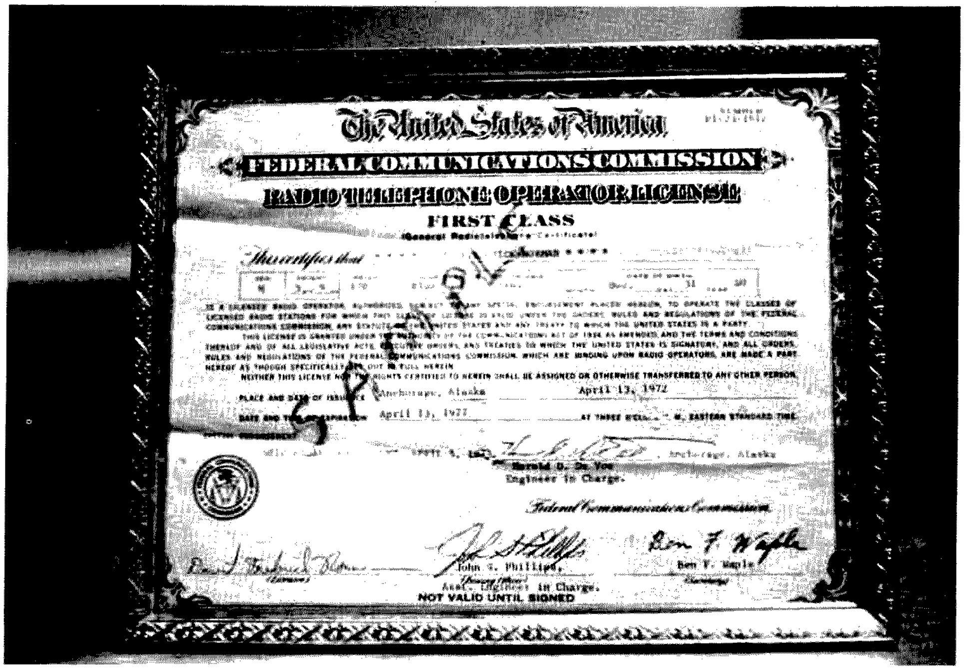

Fig. 1. An FCC First or Second Class Radiotelephone license is well worth the trouble it takes to get it.

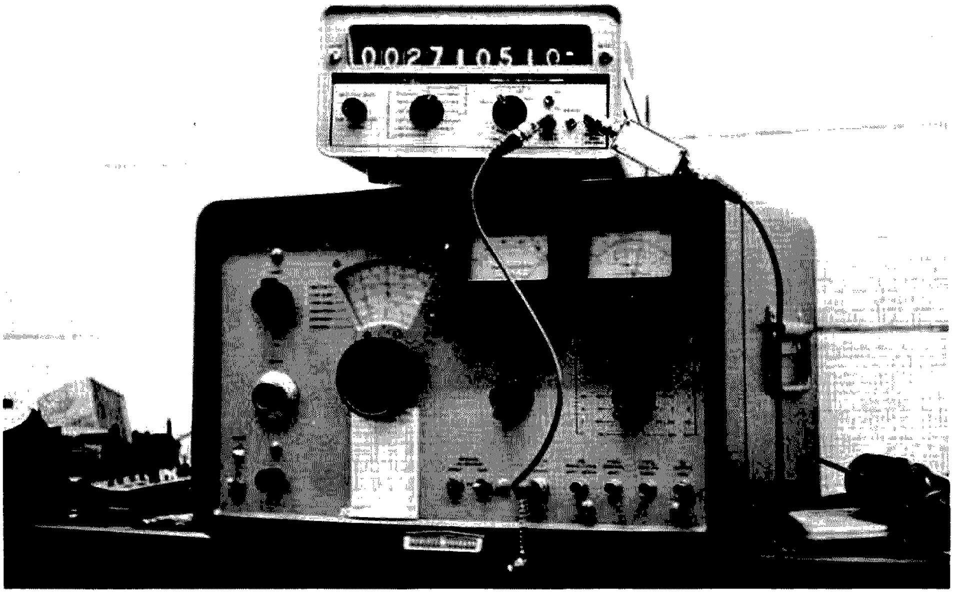

Fig. 2. Stable signal generating and frequency measuring equipment is essential for profitable CB service. Many hams already have such equipment sitting idle on their bench.

microvolt with adjustable amplitude modulation is hard to come by on a budget (Fig. 2).

In order to do the job with less equipment, you may have to constantly check the frequency output against your shop counter or frequency meter. This takes time and, if overlooked, can mean that the whole procedure must be redone. One technician solved the problem with an old CB transceiver.

This particular unit had good oscillators, but the power stages had been fried by reversing the power polarity and overfusing. The buffer stage was still good in the transmitter and the audio driver still worked.

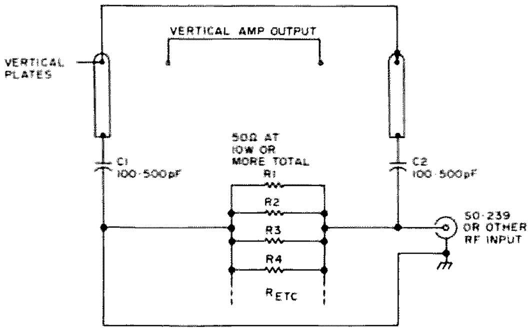

Fig. 3. A simple modification will permit practically any scope to directly handle 27 MHz transmitter output. A visual indication of modulated rf output can tell a technician not only how much modulation is present, but also how much distortion is present as well. On some scopes, it may be necessary to build the termination/coupling network so that it may be removed from the circuit when not in use. Care should be taken to see that the vertical amplifiers are not fed excessive levels of rf; average CB units will have 13-15 volts rms of rf across 50 Ohm load. Resistors should be carbon — not wirewound — paralleled as necessary for 50-52 Ohms total with a power rating of at least 10 Watts. Values of C1 and C2 should be adjusted for adequate deflection with minimum loading or swr on input.

He stripped out all of the damaged circuitry and coupled the buffer output to the antenna terminal. He then jiggered around with the driver in the audio section until he got feedback on it. This tone was adjusted, by varying the amount of feedback capacitance, and coupled through a pot to the buffer stage in the transmitter. The push-to-talk switch was replaced with a toggle switch, and he had a reasonably useful crystal generator with variable modulation. There were only two drawbacks.

Some of the crystals were off-frequency several hundred Hertz and the rf spray from the unit was terrific. Our hero merely disconnected the offending crystals and installed the unit in another chassis. When the seams were sealed with aluminum tape, spray was reduced to a tolerable level. A homemade attenuator between the original chassis and the outer chassis allowed him to reduce the output to close to one microvolt.

As units vary considerably, and this particular one is reposing in a junk pile somewhere, no specifics are offered for such modification. The item was mentioned strictly for its inspirational value. If you don't think that the idea is worth toying with, though, just try to price a commercial piece of equipment designed to do the same thing.

Scope

There is probably more controversy regarding the use of a scope than there is about all of the other test equipment combined. Some technicians use a scope for practically every test that they make, and constantly monitor the performance of one thing or the other with it. Other technicians seldom use a scope except for audio work. Most of us take the middle road and use the scope anytime that we need to compare audio or rf voltages and need the frequency discrimination provided by the scope's adjustable sweep rate.

Most inexpensive scopes share two disadvantages. They are grossly insensitive at high frequencies, and input impedance is so low that many small-signal circuits are swamped by the probe. At high frequencies, low capacitance probes usually lower overall vertical gain even more than do regular probes.

Obviously, one solution would be to get a 30 MHz scope. Unfortunately, the price of such exotic tools is quite high, even when they are surplus. Another solution is to buy a scope with as high a frequency response as the budget will stand and use it wherever possible.

For CB work, the wisest choice is probably to opt for an inexpensive 5 MHz scope and add blocking caps and a dummy load to the vertical deflection plates for viewing of modulation patterns. See

Fig. 3.

Electronic Voltmeters and Multimeters

Each CB shop needs at least one high impedance electronic voltmeter and at least one small, tough VOM for the abuse which such instruments always get. The old H-P 410B with the UHF rf probe is always a good choice for the budget bench. Not only are these instruments accurate, but they are also fairly cheap now.

With the whole world racing to become metric and digital, there are still some old ways that are better. Maybe the digital meters *are* handier for most purposes, but it is hard to beat an analog meter when it is being used to monitor a tuning response. Perhaps someone would prefer to dip a final with a digital meter, but most people prefer the smoother swing of a needle. The point is simply that brand new digital equipment is not indispensable.

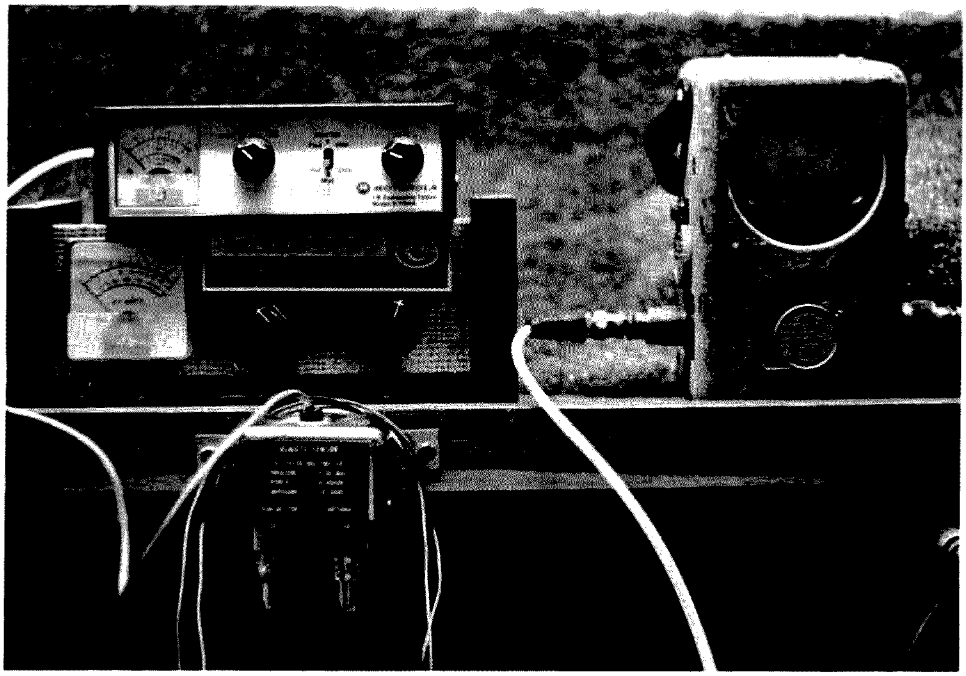

Fig. 4. FCC Rules require that CB rf output not exceed 4 Watts. These instruments measure reflected power or swr, as well as forward power.

Swr Meters and Wattmeters

A well-equipped ham shack has some means of measuring rf output power and either vswr or reflected power (Fig. 4). Legal CB transceivers, however, operate at very low power levels compared to most amateur equipment. This being the case, you may have to purchase special test instruments for CB service. If there is a Bird in the house, all that is necessary is an element for high accuracy at CB frequencies. If not, one of the multi-purpose CB transceiver testers on the market will do just fine.

The scope dummy load mentioned earlier can be calibrated against a known reference to handle bench checks, and a separate swr meter will handle the tests into operating antennas. The swr meters are not expensive and usually are quite reliable.

Bench Power Supply

Most of the transceivers which you will service are mobile 12 V dc units which draw about 1 to 2 Amperes at 13.8 V dc. A regulated and metered bench supply is absolutely essential for profitable CB service. In lieu of a neatly packaged bench supply, a battery with a well-filtered charger and a voltmeter/ammeter readout in the bench panel (Fig. 5) works very well. If you like to build and design, add switches to control charging, a circuit breaker to protect the meter and equipment being serviced, and as many status lights as desired.

A good bench safety feature is a panic button which will shut down all ac line power at once. If the ac switch — which can be an inexpensive wall panel circuit breaker — and the dc switch are mounted close together, you can kill everything instantly when you get smoke — as you surely will sooner or later.

Antennas, Library, Jumpers, and Misc.

This last category is sort of a catchall. But watch it. The shop antennas, technical library, and various cables for connecting this to that can entail a considerable investment. However, to attempt to service CB equipment without them is to turn what could be a good part-time business into an expensive hobby.

If you intend to offer installations — and you should as part of the service — you can expect to lay out more bucks for tools. Don't try to cut corners with your hand tool budget. There is nothing in this world more frustrating than having a

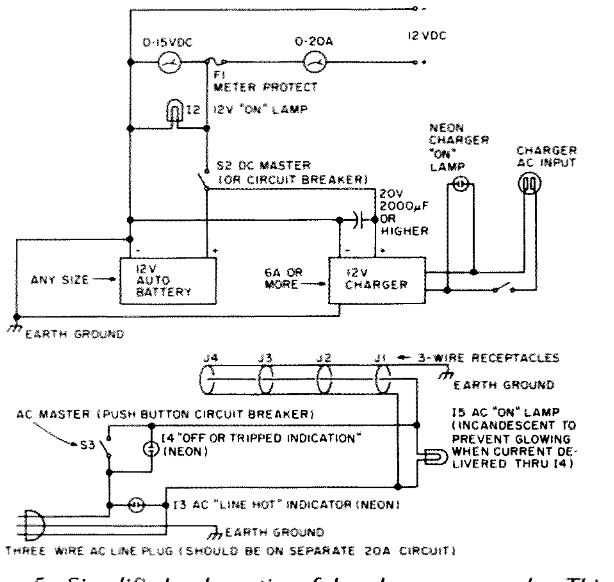

Fig. 5. Simplified schematic of bench power supply. This battery supply provides plenty of stable, well-filtered dc power. While few CB units use more than 2 Amperes at 13.8 V dc, the ambitious technician may soon find himself expanding into other fields. I4 may be omitted if it is desired to remove all leakage.

cheap tool break right in the middle of a job. If the customer is looking on, it's even worse — it's unprofessional as hell.

Parts Inventory

Most CB units are combinations of very common parts — resistors, caps, diodes, transistors, etc. — and extremely rare parts — channel selector switches, crystals (sometimes impossible to get even on new units), and special chassis parts. In most cases, the manufacturers can supply you with the parts unique to their respective units — for a price and after a time. In other cases, the time and expense involved may make the job economically unfeasible.

There is no pat solution to the parts problem. You may find that it is worthwhile for you to accumulate a few junkers of assorted brands. Some parts may be available from a "manufacturer" who markets a unit nearly identical to the one on your bench but under another name. This is where your most important tool comes into play — your brain.

No matter how limited your budget or cramped your quarters, you always have room to keep your brain. This handy item can often take the place of a whole shelf of test equipment. Remember that most problems can be diagnosed without taking the unit out of its case — if you only know what symptoms to look for and what they mean when you have them. This same tool can pull your fat out of the fire when you remember that the unit on the bench is just like the one that you have in the junk pile except for the label on the front.

One way to take care of this tool and even improve its performance is to keep a notebook on every job that you do. After a few months, the data begins to add up to increased profits. ■

Patch Up Your 101

- - simple mod for the HW-101

Edward W. Robinson K7VUA
31033 42nd Ave. S.
Auburn WA 98002

I had a dream for several years to own the Heath SB-100 — then the SB-101 — then the 102, but I never could quite get: a) the XYL to buy the deal; and/or b) the green stuff together to swing the deal! Finally, I realized that second best was "on-the-air best," so I laid out for the HW-101. I already had the phone patch and electronic keyer by Heath. In the dream days of the SB series, I had even bought the assembly manual for the SB-102, so I had quite a familiar start with the new project.

Anxious to have the phone patch, I was surprised to find no mention of it in my first "charge" through the assembly manual for the 101! I checked the index and every part of the manual, carefully studied it even — no mention at all. Hmmm!

Then I went back to the SB-102 manual, and careful study revealed that it would be quite a simple matter to add the patch to the HW-101. And, the place already existed for the parts needed when I checked the Modulator Circuit Board in my kit. The holes are drilled and the board appears to be the same one used in the SB-102 unit.

All that's needed is a ½ Watt, 22 kΩ resistor, 2 feet of RG 174/U coax and the spare jack on the back of the HW-101 chassis. If you are putting a new kit together as I was, provide for it at this time. If not, just remove the covers and get down to where the action is.

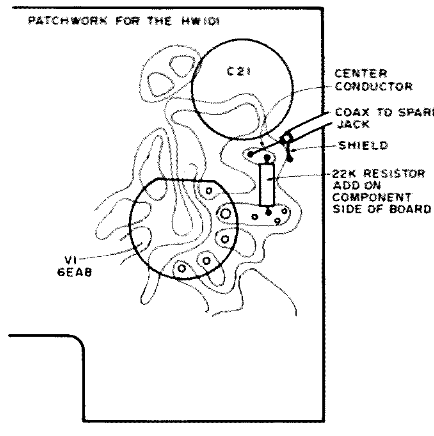

Fig. 1. Modulator circuit board (foil side).

Fig. 1 shows the corner of the modulator circuit board right around V1, foil side up. This is also available to you kit builders on page 188 of your manual, and is the upper right-hand corner of the illustration. The 22 kΩ resistor goes in the position indicated. Then the coax is put in as shown: the center conductor to the same island as the resistor and the braid to the outside or ground portion of the board. Holes are already there for the components.

Next, dress the coax back to the spare jack on the rear of the chassis. There you solder the center conductor of the coax to the center lug on the jack, and solder the shield to the ground lug. Be sure that you make a neat job of the coax as it runs back through the chassis; tie it off or thread it so that it will stay in place. Incidentally, there was enough spare coax in my kit to make up the piece for this purpose. If not, a 2-foot piece of RG 174/U will do the job.

Now all you need do is plug in your phone patch and you're ready to go. Since most of the components are the same as for the SB-102, you have actually made your kit more valuable, if you have done it neatly.

Happy patchwork! ■

The History of Ham Radio

-- part IV

Eric Shalkhauser W9CI
527 Spring Creek Road
Washington IL 61571

During 1921, for sending their signals, amateurs were still thinking in terms of spark transmitters. The vacuum tube, as a simple three-element detector, was being advertised prominently and illustrated profusely in all the wireless literature. Not until the VT-1, 201, 202 and other tubes came along could much conversion from spark transmitters take place. It was well into the 1921-1922 period that this happened with the realization that wavelengths below 200 meters were of considerably more advantage for DX and better tuning characteristics than at 200 meters and above.

While in the Signal Corps Officer's Training Camp in College Park MD in 1918, I saw and operated the first three-tube transmitter. It was similar in appearance to the first three-tube DeForest set which was extensively advertised in radio periodicals in 1921. It came equipped with Western Electric VT-1 tubes.

Construction articles appeared monthly in the 1920 and 1921 magazines. These were simple circuit diagrams showing application. The Fessenden, Marconi, the Telefüncen, the Colpitts and many others were displayed. The radio amateur was doing a lot of experimenting in adapting this new device to all sorts of circuit layouts toward improving reception and transmission of signals.

Amateurs and commercial interests devised all sorts of receiving circuit combinations under such names as the *neutrodyne*, the *amplidyne*, the *Roberts*, the *Cockaday*, etc. One must remember that radio broadcasting had its real beginning in earnest right after World War I, and the general public became all agog over this new mysterious phenomenon entering their homes. Hearing strange voices and music out of nowhere . . . through earphones . . . without wires . . . It was unbelievable!

From now on the ham was no longer alone with his dots and dashes in his little cubicle, carrying on his own brand of mysterious private conversation.

Serious consideration was being given by the amateurs to the possibility of making improvements in signal reception by adding several stages of tube amplification to the detector. The single crystal detector and the old coherer could now be permanently replaced and abandoned. Those weak and often inaudible signals could now be picked out with ease and at a greater distance. And so, with the discovery of the regenerative circuit by Major Armstrong, the vacuum tube *started to oscillate* and gave signals a thousand fold boost in strength.

Peoria Radio Sales Co., 1923-1924.

The vacuum tubes were not quite ready for transmission purposes. Their lack of ruggedness, their size, their cost and their scarcity held back adaptation by the amateur fraternity of tubes for strong CW signal generators. After the war, and even into 1922, amateurs who had served Uncle Sam were still operating their spark transmitters.

Many of us were familiar with either the Army Signal Corps or the Navy gear. They all looked and operated alike. In the beginning of wireless adaptation to the armed services, very little innovation could be expected for field combat purposes. The quenched gap transmitter stood out as a most reliable unit. To the ham this was proven equipment. True, it operated in many instances from a 500 cycle source of

power, but it was regarded as a dependable unit to cover fairly long distances and was used by commercial companies in the field. It was semiportable when loaded on a horse, a mule, or two-wheeled cart.

The returning amateur was trained in the use of such transmitting equipment and took a fancy to the unit. He was very familiar with its performance, knew how to operate it, and had practical knowledge of its capabilities and application. During his period of service he was always thinking in terms of adapting it to his own use if and when he got back home. The one and only drawback was the 500 cycle power input. Replacing the quenched gap in the circuit proved a minor drawback.

When we examine the spark gap circuit used in all stations as illustrated and described in the literature of the early 1920s, it can be said that it was really quite simple and direct, and not difficult to understand in operation and performance.

The "spark-gap-ham" preferred to build his own condenser. He would use glass plates, mostly 8" x 10" in size, obtained from a photographer who was ready to discard them. (Exposures were made on glass plates "in them olden days.") These were covered, both sides, with tin or aluminum foil or other thin metal sheets. Tobacco pouches were often sources of foil. Enough plates were coated so that the assembled condenser gave a value of .01-.012 uF. To make sure that the unit could withstand potential surges as high as 25,000 volts, four of these sections were connected in series-parallel, making the capacitance still the correct value, approximately 0.01 uF. The whole thing was immersed in oil. Not to do so caused corona discharges around the edges. Being well soaked made them stand up much better under the high potentials. Even then they punctured unexpectedly!

The high potential was quite dangerous around the place. It was important that the condenser box be surrounded by a protective wall and openly marked: DANGER — HIGH VOLTAGE — KEEP YOUR DISTANCE!

The discharge gap in the circuit is in series with the primary spiral inductance, usually made of flat-wound brass or copper ribbon. This was known as the oscillation transformer. Every time the key in the low voltage primary circuit was closed, the charged condenser let loose for the shortest fraction of a second, in rapid fire, and discharged across the spark gap. On discharge, the energy surged around the helical coil, and, in turn, the secondary coil inductively coupled to the primary received a burst of electromagnetic energy. This in turn sent a damped wave signal out into the ether by way of the antenna configuration. A hot wire ammeter in series with the antenna to ground connection indicated the amount of current being emmitted. A fuse block in the main power line provided protection against overloads.

Although the circuit

looked quite simple, we amateurs had other problems to contend with in meeting the 200 meter (or less) wavelength requirements. The condenser design value had to stay within the above stated uF limits. I will not attempt to delve into the mathematical equations to prove the point. Remember that we had a wrong concept of wavelength versus distance in those days.

Some amateurs were in a position to obtain 500 cycle power generators. Many signals could be heard on the air using such units. The signal coming from a 500 cycle source had a distinct tone quality. It was music to many an ear.

By way of interest, here is a statement which appeared in *Radio Amateur News* in 1920:

> "Surely the US government is not imposing upon the American amateur when he limits the operating wavelength of your transmitter to 200 meters. Contrast this law to that of Canada where the limit is placed at *50 meters*. As a Canadian amateur recently remarked, with this short wave we may consider ourselves fortunate indeed to cover the extraordinary distance of one mile. As for democratic England, the would-be amateur is simply out of luck, for no license or permission is at present even obtainable under any condition. From the foregoing, we may therefore deduce the timely moral: *Keep your transmitter on the lawful side of 200 meters*."

The amateurs up to now had really not discovered the potentially great advantage of the shorter wavelengths.

The rotary gap caused havoc on many occasions, since the studs had a tendency to become pitted after a short time of operation unless constructed of stuff that withstood the constant arcing in an open oxygen atmosphere. Of considerable help was an enclosed gap, sufficiently airtight to exclude oxygen to the extent possible.

Much experimenting with the number of studs on the rotor and the speed of the motor improved the efficiency of the system. An 1800 rpm synchronous motor and a wheel with twelve well-designed studs, made of material that could withstand pitting, usually provided the right kind of pitch and whine to satisfy the critical ham in his quest to excel on the air.

By the characteristic frequency over the air, most ham stations were recognized without the usual QTH report. "I know the sound of his spark" was a common remark among hams.

After a station had its mechanical problems fairly well under control, the problem of decrement of the signal emitted received considerable attention. Specifications from the bureau in Washington decreed that the decrement could not, or should not, be higher than 0.2 when the energy was transferred to the antenna. Otherwise the signal emitted would be unduly broad with accompanying increased interference due to high damping.

What was this decrement all about? The subject was discussed at great lengths. It took front and center attention and was good for an argument anywhere, anytime. Decrement and how to meet its requirements waxed hot and furious from many podiums at conventions. Today you never hear the subject mentioned any more.

Decrement, logarithmic decrement: Nobody knew very much about the subject, even though the Department of Commerce issued their well known Bureau of Standards book entitled *Radio Instruments and Measurements #74*, on March 23, 1918. This gave technicians and engineers an in-depth documentation on the subject. Mr. B. West ex-8KEZ discussed spark dischargers at the St. Louis convention in 1920. In the course of his presentation, he was interrupted repeatedly by well-meaning listeners in the audience, as they confused the issue by introducing the "damping factor" and then wondering what was meant by *napierian*. The confusion usually brought down the house, and the heated discussion ended in a draw. Not even well-meaning intellectual cowhands from the western ranches knew what to make of these arguments and decided to leave well enough alone when they got back to their radio shacks.

So decrement, damping factor, impulse excitation, and increment — all these factors — were eventually solved the usual "over-the-ether-waves-reporting" way — experimentally — trial and error methods prevailing. It was understood that a low resistance (the lower the better) in the secondary discharge circuit gave a low decrement and allowed the energy to oscillate freely with consequent low heat loss. We seldom worried about impulse excitation any more.

Our problems were put away for a while until the next convention came along. This was to be the First National American Radio Relay League super meeting at the Edgewater Beach Hotel in Chicago, to be reviewed in the next chapter.

We go back to our midnight operating hours when all is quiet and serene about the house. The ham does not want disturbances to interfere with his concentration on distant code from some far-off place. Besides, when the key is closed, the spark noise could disturb the neighbors, and any intruders into the privacy of the shack would be overcome by the ozone that often permeated the atmosphere. QRX till we meet later on when fully recovered in fresh air environment. ■

Dipole Designer Program

- - calculates coils and length

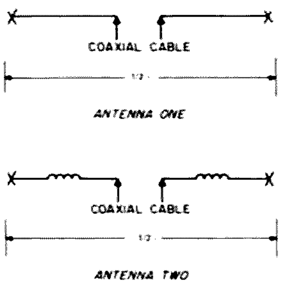

Fig. 1. Dipole Antenna Considerations.

The resonant half wavelength dipole can be shortened considerably using a pair of loading coils to provide lumped inductance between the center feed point and the ends of the antenna (Fig. 1). Both of these configurations can be resonant at the same frequency.

What's the tradeoff? The reduced physical length costs you bandwidth at any swr level of your choice. If you're using less than a couple hundred feet of RG-8 or RG-11 and your lot is as small as mine, then that's an attractive exchange.

The Dipole Designer program is written to help you juggle the variables involved. It can be broken down into 3 areas.

Program Description

The first area is the calcu-

Program listing for Loaded Dipole Design program. Written in Digital Group Maxi-BASIC Version 1. (Program plus BASIC requires approximately 17K.)

```

lation of the size of the inductive loading coil you will need to insert in each leg of the antenna. The computer asks you to input:

a) the desired resonant frequency in MHz;

b) the distance in feet from the center of the antenna to where you want to place the loading coils;

c) the size of wire you are going to use in constructing the antenna. This information is entered as wire gauge size. Buried in the program is a wire gauge to wire diameter conversion lookup table;

d) the overall length from end to end that your new antenna will have to be in order to fit in the space you have available.

The computer will then promptly display the inductance in microhenrys required to meet the above design variables.

```

Sample run of Loaded Dipole Design program.

At this point you're probably wondering where you stashed that coil design slide rule. Look no further, because that's section two of the program.

First you're given a choice of starting with the value of inductance just calculated or a new value. In either case it's in microhenrys. The program then asks you to input:

a) coil diameter in inches, and

b) the number of turns per inch you plan to wind the coil at.

Using this data the computer will return both the overall coil length and the total number of turns required to obtain the design inductance.

Curious about what effect the wire size really has? How about changes in overall length? Or what happens when you move those coils away from the center of the antenna toward the ends? The third section of the program takes care of these variables.

Using the Program

Just select the appropriate option after the list is displayed and a table will be generated showing the change in inductive load (in microhenrys) with one of the design parameters changed over a wide range.

The first option is an analysis of what happens when feedpoint to loading coil distance is changed. The inductance of the loading coil required to produce resonance is listed in one column of the table and the center to load distance in a second column. The number of feet the coil is from the feedline starts at 5% of the overall antenna length you previously inputted and goes to 45% of the overall length in 5% increments. Does the inductance of the coil increase or decrease as it moves away from the feedpoint?

Choose the second option, and your computer will generate a table of load inductance in one column

and overall dipole length in the other column. The center to coil distance you originally specified is used. The overall antenna length starts at 2.4 times the center to coil distance and goes to almost one half wavelength. Sure enough, the inductance approaches zero as the overall length approaches half wavelength.

How about the wire size? Why is it even taken into consideration? Well, choose option three and look at a comparison of required inductive load to wire size with wire size going from 6 gauge to 28 gauge in steps of 2. Interesting.

A few comments about the program. It runs in about 4.6K of BASIC, not counting the memory consumed by the BASIC interpreter. I have it running on an 18K Z-80 Digital Group System. If memory capacity is a problem, the program can be chopped into 3 major areas described and portions deleted as required.

You could also delete the wire gauge to wire radius conversion section and enter wire radius in inches, to save a couple hundred words.

There are no remarks. However, I think the liberal use of print commands makes the program fairly easy to follow.

Formatted print commands were deliberately avoided to save confusion in applying this program with different systems. The language is Digital Group Software Systems Maxi-BASIC Version 1.

How about adding a section for inverted vee configurations? Extracting the loading for verticals and whips should be relatively easy, too. ■

Software Control

-- for High Quality Video Display

Don Alexander WA8VNP
Microcomputer Ventures, Inc.
4497 Indianola Ave.
Columbus OH 43214

In the March, 1977, issue of *73* I described a video display which is seen to be a part of memory by the computer. This article is to present a software driver for that display.

The operation of the display is essentially that of a window to a portion of the computer's memory. The computer can read or write randomly to any portion of the display memory just as it can with its normal memory. In fact, programs may even be executed from the display memory. When the processor is not accessing the display memory, the display circuitry takes over and uses that memory to generate a video signal. As a result, display functions such as line feeding or erasing are software processes.

The program provides these basic functions:

1. Carriage return;

```
Video Display Driver    MAC80 Version 2(30)-2 running on  5-May-77 17:52:42      Page 1
File DSKA0:VIDEO.M80[4,40] created  5-May-77 17:50:00

                              TITLE   Video Display Driver

                        ;     This routine is a general purpose display driver.  A character  is
                        ;supplied  in  the  accumulator and this routine is invoked causing that
                        ;character to be transferred to the display memory.  If  that  character
                        ;is  a  control  character,  then a special action may take place such a
                        ;clearing the screen or changing the location of the cursor.
                        ;
                        ;     The following calling format is used:
                        ;
                        ;       LXI     H,BLOCK  ;Get the argument block
                        ;       CALL    VIDEO    ;Invoke the display processor
                        ;       always return here
                        ;
                        ;BLOCK: DB      n        ;Beginning line of display block
                        ;       DB      m        ;Ending line of display block
                        ;       DW      addr     ;Address of next character (updated by VIDEO)
                        ;
                        ;     A "display block" is a group of lines on the screen that are acted
                        ;upon together.  If the block is scrolled, for example, only those lines
                        ;between the starting and finishing lines are scrolled.  The "cursor" is
                        ;the  location  of  the  next  character  on  the screen.  The cursor is
                        ;represented on the screen by inverting  the  video  at  that  location.
                        ;Most  characters  are displayed at the current cursor location and that
                        ;location is advanced one position after  each  call  unless  a  special
                        ;character changes the cursor address.
                        ;
                        ;     The following special control characters are recognized:
                        ;CR     carriage return Move the cursor (next character position) to the
                        ;                       beginning of the current line.
                        ;LF     line feed       Move the cursor down one line.  If there are  no
                        ;                       more  lines  in  the block, then the rest of the
                        ;                       block  is  scrolled  upwards  and  the   cursor
                        ;                       position is unchanged.
                        ;BKSP   backspace       Move the cursor backwards one character.  If the
                        ;                       cursor  is  already  at the leftmost position on
                        ;                       the screen, then no action is taken.

Continued

2. Line feed;
3. Backspace;
4. Horizontal tab;
5. Form feed (erases the display);
6. Clear line;
7. Bell (an inaudible bell, no less);
8. Cursor;
9. Do nothing. (Most terminals accept a filler character which does nothing.)

Calling parameters to the program are used to define the beginning and end lines of the display block to be used and to specify the current cursor address. On return from the display routine all registers and status flags are restored, and the cursor address in the parameter list will have been updated.

Most normal applications of the display use all 32 lines and therefore would specify lines 0 and 31 in the parameter list. But, referring to page 82 of the March, 1977, *73*, you will see an example where I have several display blocks in use simultaneously.

(The picture on page 83 is labeled as split screen but it is not. It is merely an assembler listing.) In the example on page 82 I have the screen split into four blocks, two each of one line and two larger blocks. The program which is receiving the RTTY calls the display routine using lines 2-11 in its parameter list. Likewise, the transmitter routine calls the display driver using lines 15-31. The two one-line areas are from special function routines which call the display driver with the beginning and end lines defined to be the same.

The cursor function is provided by using the inversion capability of the display. Any character may be displayed as white on black or black on white as described in the March article. The software presented here uses that feature for the cursor and to implement the inaudible bell (invert the entire screen for about a half of a second.)

The cursor address is part of the calling program's parameter list since it is possible (as illustrated above) to have more than one cursor. Use of the display is facilitated by having any routine which uses the display driver to initialize its corresponding display block. This is accomplished by calling the display routine with a form feed (octal 14) in the accumulator. This will erase the specified portion of the display and will initialize the cursor address in the calling routine's parameter block to point to the upper left character of the display block.

The program listing is reasonably well documented so you should be able to follow the program flow without too much trouble.

I do want to mention that in the schematic on page 78 of the March *73* the line labeled "011" (center-left in the schematic) should be labeled C7. Also, the text on the same page says that part of the row counter is a 7490. It is really a 7493 as the schematic indicates.

I wish to express thanks to Victor Kean WA1LKU who took a program listing from my model 19 Teletype, complete with comments in freehand scrawl, and retyped the source and comments on a local DEC-System 10 to produce a readable listing. ■

QSL Tips

-- how to bat 1.000

Marty Barrack
200 S. Lincoln
Sterling VA 22170

This month we interview Sir Henry Peter Fox, the world's greatest authority on QSL cards. Sir Henry works as a gun bearer on the Dark Continent, keeping the natives restless. He used to teach marksmanship until one of his students, Albert Scaramanga (known to his CB buddies as the Triple Nipple), tried to shoot a member of the British Secret Service. Ruddy awful business! After that, Sir Henry turned to QSL collecting. When we approached he was explaining to one student how to tell from looking at the edge of a QSL where the tree from which it came grew and the time of year it was cut down. In response to another question he named every ham in the world from memory, how many countries he had confirmed, and exactly how many cards he had outstanding and at which bureaus. I asked Sir Henry how to get a lot of QSL cards. He replied, "Get a CB and wait until 1980." I explained that we were interested in ham QSLs. "Oh," he said, "order from Brownie by the thousand." I tried again. "No. Already filled out." "Ah, why didn't you say so? Rob a QSL Bureau."

Sir Henry downed a Bud and continued, "There are two ways to get QSL cards after you work a station. You can send your card directly to the station you worked, or you can send it through the bureaus." I asked why go through all the intermediary bureau stages. His answer was strikingly clear. "Money." He explained that, to send a card directly, you have to fill in the data, look up the DX station's name and address in the callbook, and type it on a 9½" envelope. Then you type your own name and address on a 6½" envelope. If you can get it, put sufficient air postage in the stamps of the DX country on the small envelope. Otherwise, put several International Reply Coupons in the large envelope. Also put in the large envelope your QSL card, properly filled in, and the small envelope. Then put sufficient U.S. stamps on the large envelope and mail it promptly. Odds are such a mailing will cost about two dollars in IRCs and stamps for just one card.

I told him it seemed very expensive. He opened another ice cold Bud and went on. "It is. But it's fast. You have to decide for yourself whether the speed is worth it. Usually, if you have a small station and only work DX occasionally, you may as well get your souvenir fast and direct. But if you work 'em three a minute, your costs will go out of sight. Now, the bureau system will do the job slower, but for a fraction of a penny per card! Start by filling in all your cards, just the data section, don't address them. Then put them in alphabetical order by prefix. Put the cards in a box with a dollar and a copy of a current *QST* mailing label and address it to Outgoing QSL Bureau, ARRL, 225 Main St., Newington CT 06111.

"ARRL sorts the cards and mails a bundle off to each foreign bureau every week. Then it takes 30-90 days for the surface mail to travel from ARRL to the foreign bureau. Then figure 30-90 days for the foreign bureau to sort it and get it to the foreign ham you worked. The ham will probably take about 30 days to actually fill in his card for you and send it back to the foreign bureau. The foreign bureau may take another month to six months to get it on a boat; the big foreign bureaus such as DL, G, YU, F, ON, etc., will usually get a card out within a month. Then figure another 30-90 days on the high seas before the card gets back to the U.S. Then it goes to a U.S. bureau. The fellows in the bureaus, by the way, are the real unsung heroes of DXing. They do a super job of sorting. Every DXer in the call area keeps a 5" x 7" manila envelope, self addressed and with 13¢ postage stuck on and another 13¢ stamp clipped on, on file. The bureau man with your letter puts all the cards addressed to you in your envelope. When the weight of the envelope approaches the maximum postage limit, the bureau mails it off full of cards you earned the year before!"

"Will they really do the same job?" I asked. He fondled the beautiful woman sunbathing at his side and said, "Look at two guys in the Sterling Park club. WA4HPF has 260 countries confirmed and spent about $200 in IRCs. K4VT has 260 countries confirmed and never spent a dime. Of course, K4VT has been around a lot longer."

I asked Sir Henry how many countries he had. "Eleven," he replied proudly. I told him it seemed a small number compared with N4KW's 300+ countries, and asked if N4KW was a better operator. "You asked how many countries I had," he answered. "I *own* eleven countries. I have QSLs from every country, naturally."

I questioned Sir Henry about the practice of putting a dollar bill in with a directly sent QSL to encourage the DX to send his card in return. "Yes," he said, "some of the less experienced fellows do that. The sharp boys know how to do it right. You open an irrevocable letter of credit with a bank in the DX station's country. When the DX station sends off the card the bank releases a draft to the DX operator."

The sun was starting to set. Its orange light reflected off Sir Henry's station, especially the shiny black Collins HF-80s. Outside I could see W6AM patiently waiting to ask Sir Henry Peter Fox how to work DX and get QSLs. I shook Sir Henry's hand warmly, wished him well, and took out the ropes and pitons for the long trip down. ■

CB to 10

-- part III: converting the TRC-47

With the slowdown in the CB boom and the recent expansion to 40 channels, the CB equipment manufacturers have been caught off guard with thousands of 23 channel radios in warehouses. These are being dumped on the market at very low prices. I've seen advertisements as low as $39.95 for a 23 channel AM rig. A very good one can be had for well under $100.00.

Most of these radios are very easily converted to ten meters at a cost of under forty dollars.

First, for those of you not familiar with the way these crystal synthesized rigs operate, a few basics, then I will go into specific details of the conversion of a Radio Shack TRC-47, a very common AM & SSB rig.

There are two basic 23 channel synthesizer schemes, the 14 crystal and the 12 crystal. First the 14 crystal type, the more common.

The 14 crystal radios usually have a single conversion receiver with an i-f of 455 kHz. The crystals are in three groups which I will call group A, group Bt, and Br. In my example, I will use the following crystal frequencies: group A – 16.465, 16.515, 16.565, 16.615, 16.665, 16.715; group Bt – 10.500, 10.510, 10.520, 10.540; group Br – 10.955, 10.965, 10.975, 10.995.

In operation, one crystal from group A is used, and one from group Bt on transmit and one from Br on receive. For example, on channel 1 (26.965 MHz) on transmit, 16.465 and 10.500 are mixed to get the operating frequency, and on receive 16.465 and 10.955 are mixed to get 27.420 MHz, which conveniently just happens to be 455 kHz above the operating frequency of 26.965. So if we add 1.735 MHz to each crystal in group A, we can get frequencies in the range of 28.700 to 28.990 MHz, with channel 9 working out to 28.800, the AM calling frequency. How about that?

So, with a 14 crystal AM rig, all that has to be done to put it on ten is to change six crystals and retune some coils. With minimal test equipment, a VTVM, signal generator (that old VFO), a wattmeter or swr bridge, and a dummy load, the whole job can be done in under one hour.

The most difficult part of the job is figuring out what crystals to order. Table 1 is a chart of the common heterodyne scheme and channel frequencies. Notice the 10-10-20-10 kHz spacing of the channels.

Note the channel marked ** is indicated by the dot on the dial between 22 and 23 and on some radios can be had by just installing a jumper or clipping one. Some other radios would require major mechanical modifications to the channel switch to get it.

When you decide what frequencies on ten meters you want, on the 10-10-20-10 spacing pattern, just subtract 26.965 from the lowest one and add this result to the frequency of each crystal in group A, order the new crystals from your favorite purveyor of quartz, wait for the post office, wait for the post office some more, and, when they come, get out the old trusty soldering iron and swizzle sticks, and soon you'll be on ten.

Now, for the 12 crystal rigs. These are cheaper to convert, as only 2 have to be changed. The receivers in these are usually better because they are dual conversion. The heterodyning scheme here is similar to the 14 crystal type but there are only 6 group A and 4 group B crystals, and 2 i-f crystals. Table 2 is an example from a Sanyo TA-923 which I still use on 11 meters.

In this type of radio, one crystal from group A and one from group B are used for both transmit and receive and are mixed to form a product in the 38 MHz range which is run through a bandpass filter at this frequency.

An example for channel 09 (27.065 MHz): Grp A = 23.390; Grp B = 14.950; A + B = 38.340 MHz.

On transmit this 38.34 MHz is mixed with 11.275 to get the operating frequency of 27.065, run through a bandpass filter at 27 MHz, amplified, and modulated. On receive, the 38.34 is injected into the first mixer to get the Rx first i-f at 11.275, which is then mixed with the 11.730 to get the second i-f of 455 kHz. Simple, isn't it? All that has to be done here is to lower the 11 MHz crystals by the amount you want to go up in operating frequency. For example, to make channel 09 come out on 28.800 lower them by 1.735 MHz making the Tx i-f = 9.540 MHz and the Rx i-f crystal = 9.995 MHz, retune the appropriate coils, and you're on the air on ten.

Now, down to the real nitty-gritty of one that I have had on the air on SSB for several months now, in use both at home and in the car. The one I picked is a Radio Shack TRC-47, about the same size as an Icom IC-22. It has a very good crystal filter centered at 11.2735 MHz which gives about 50 dB unwanted sideband suppression. The TRC-48 uses the same filter and oscillator PC board, so conversion data for it is identical to the TRC-47. The TRC-48 is slightly larger and fancier (it has an "S" meter, PA, and switchable noise blanker) and more expensive. They are both rated at 4 Watts rf output on AM and 12 Watts PEP on SSB. I am getting 10 Watts PEP out of mine on 28.600

Grp A/Grp Bt	10.500	10.510	10.520	10.540
16.465	26.965-01	26.975-02	26.985-03	27.005-04
16.515	27.015-05	27.025-06	27.035-07	27.055-08
16.565	27.065-09	27.075-10	27.085-11	27.105-12
16.615	27.115-13	27.125-14	27.135-15	27.155-16
16.665	27.165-17	27.175-18	27.185-19	27.205-20
16.715	27.215-21	27.225-22	27.235-**	27.255-23

Table 1.

MHz. That's only 10 dB down from the typical SSB exciter which has at best 100 Watts output, most of them more like 70 or 80 on ten meters. So what if I'm 1 or 2 "S" units down; it makes up for all the mobile noise from my own and other cars on the road. If I can hear them in the car, I can work them.

Now, how to do it to it.

Step 1: Getting the radio — new or used?

If you have a bit of test equipment you can probably get a better deal on a used radio, but check it out first! Check rf output on AM. If below 2.5 W or above 5.5 W when operated on 13.5 V dc or the ac line if a base station, forget it and go on to the next one. On SSB the output should indicate 8-16 Watts when you whistle into the mike. Check out the receiver on an antenna. Find a few strong local signals and make sure they disappear when switching to the next channel on either side. They should be way down when switching sidebands if SSB.

Next, take the covers off and have a good look inside for modifications. If you see any, put the covers back on and forget it, unless it is quite obvious that the mods will not affect operation of the radio in the manner in which it was designed to operate. As far as dust, dirt, and smudges go, they can easily be cleaned up, so don't let that bother you. Look for ads in the newspaper or in the local weekly *Buy and Sell*. Bargain over price as most sellers are not firm on asking price, and, after all, it's a buyer's market now for 23 channel radios, especially for SSB. Make a call to the local police to make sure it's not hot. For a new radio, shop around at a few stores. Again, it's a buyers market, and even at the chain stores you can get quite a good deal. So make an offer; they might just take it.

Step 2: Figuring it out

If at all possible, get the service manual! This will tell you all you ever wanted to know, but were afraid to ask. For the Radio Shack radios, it can be ordered from the store (they're everywhere just like MacDonald's) if they don't have an extra one in stock. It's well worth the two bucks. Most radios have a schematic diagram in the owner's manual, and some even have one glued inside the top cover. This may be all you need, but the service manual gives complete alignment information and a description of circuit operation which can help a lot.

Group A:	23.290	23.340	23.390	23.440	23.490	23.540
Group B:	14.950	14.960	14.970	14.990		
Tx i-f:	11.275					
Rx i-f:	11.730					

Table 2.

Step 3: Plotting and Scheming — just what has to be done?

Which crystals to change? Determine the type of synthesizer and do the arithmetic. If you have trouble, write me enclosing a copy of the schematic and existing crystal frequencies and one SASE, and I will be glad to help you. Next, order the new crystals and wait, and wait.

What about tuning on SSB? All the SSB rigs have a clarifier control which will move the receiver + or - about 1 kHz. On many of the rigs it also moves the transmitter the same amount. Don't worry if it doesn't move the Tx; it's easy to fix it so it will. What about moving more than 1 kHz? If you can't figure it out, ask one of the unscrupulous CB servicemen who advertize in the personal column of the local newspaper how to put in a slider. This will give you about a 20 kHz spread on each channel. Follow all signal paths on the schematic so you can figure out which circuits will need retuning.

Step 4: The Mod Squad Attacks

For the TRC-47 (and -48), which uses sort of a cross between the 12 and 14 crystal synthesizers, the existing crystals are shown in Table 3.

In this scheme, one crystal from group A is always used, one from group Bu for AM and USB, and one from group B1 for LSB only. The 11.275 is used for AM Tx and for USB. The 11.272 is used for LSB, and the 11.730 for AM Rx only.

Change the group A crystals to: 24.865, 24.915, 24.965, 25.015, 25.065, and 25.115 MHz. The clarifier control is a fairly large variable capacitor of two sections, with a fixed capacitor in parallel with each section. Clip these two fixed capacitors out of the circuit. This now gives you more range on the clarifier, about -1 to +4 kHz. Seeing as how nobody uses LSB on ten meters, remove the two resistors (1 K) which bias the diodes for switching the BFO crystals and short the diode for the USB BFO crystal (11.275). By doing this, when you move the mode switch to LSB the radio stays on USB, but you get a downward frequency shift of about 3 kHz. You now have two 5 kHz wide bands with a 2 kHz overlap for each of the 23 channels. Now retune the bandpass filters at 38 and 27 MHz to 39.6 and 28.6 MHz, peak the receiver front end, peak the transmitter driver and final coils. Do not adjust any of the pots in the transmitter unless you have access to and can use a spectrum analyzer, as this will affect drive level and bias and will affect intermodulation distortion just as much if not more than it will affect power output. The extra one or two dB you can get, just isn't worth the trouble.

Step 5: The Smoke Test

Get in contact with a local ham who can work ten meters, and arrange a sked to make sure that it is working on the frequency you think it is, and while he is transmitting on a known frequency, make sure you can tune him in where you think he should be. Then and only then, try out the transmitter to see if he can hear you. Also have him tune up and down the band to make sure you are only transmitting in one place and the radio has reasonably good audio quality. If you want to use an external speaker on it, be careful how far you advance the audio gain, as these rigs have much more audio than you will probably ever need on receive, as the Rx audio output is also the AM modulator. It will give you up to 5 Watts of audio, enough to wake the silent keys. They usually have resistors in series with the internal speaker to prevent the voice coil from smoking at an early age.

Step 6: Operating it, CQ CQ 10 CQ 10 CQ 10-10, etc.

Generally accepted calling frequencies are 28.600 USB and 28.800 AM, and activity seems to be centered about these, but it's best to check with a local who is active on ten to make sure first. There may be a local net or club using some other frequency

Group A:	23.330	23.380	23.430	23.480	23.530	23.580
Group Bu:	14.910	14.920	14.930	14.950		
Group B1:	14.907	14.917	14.927	14.947		
BFO u:	11.275	**BFO 1:** 11.272	**Rx 2nd mixer for AM only 11.730**			

Table 3.

that you may want. On many of these radios the squelch control works very well, so it's easy to monitor a specific frequency for calls, and have things quiet when there is no signal present, just like two meter FM. Local coverage, both mobile and fixed, seems to be about the same as two meter simplex operation, but more fun when it opens up, which is getting to be more often now that the sunspot cycle is on the upswing again.

Some Notes on Antennae for Ten.

For mobile operation I use one of the four foot long top loaded fiberglass whips with 12 turns removed from the top of the coil. This makes it resonate nicely at about 28.6 MHz. It's only about 1.5 dB down from a full quarter wave, and it's a lot easier to fit into the garage.

At home I use a Radio Shack 5/8 wave ground plane for 11m with the capacity hat removed, but everything else exactly as it comes out of the box and assembled following the directions. Removing the top hat (3 wires) makes it resonate at about 28.5 MHz with an swr of less than 1.4:1, not bad for an antenna which takes only about 15 minutes to assemble and erect.

What About Crystals?

They can be had from any of the manufacturers advertising in the magazine elsewhere, or you just may have some in your junk box. Canadians can order from Lesmith Ltd., PO Box 703, Oakville, Ont., at a price of six dollars per crystal. Delivery of crystals should take 4-6 weeks.

Best of luck, and hope to hear you on ten. If you have any trouble be sure and drop me a line, and I will try to help you out. ■

CB to 10

-- part IV: Johnson 123A mod

Tom Goldsmith WB4EQU
49 Memorial Parkway NW
Fort Walton Beach FL 32548

David F. Norman
622 W. Sunset Blvd.
Fort Walton Beach FL 32548

As any fool can plainly see, the transceiver shown in Fig. 1 is a very common, midpriced CB unit. Right? Wrong. This particular E. F. Johnson Messenger 123A started out that way, but a few simple modifications have turned it into a 23 channel, crystal controlled 10 meter amateur rig.

When we were finished with the modification and tuning, we ran a performance check on this unit. Radio frequency output exceeded 3.5 Watts and receiver sensitivity was on the order of 0.5 microvolts for 10 dB signal plus noise/noise. That ain't bad. With the coming increase in sunspot activity, conversions such as this should be good for some very interesting low power DX.

The idea was sparked by the realization that many underpriced CB units were made available when the CB manufacturers began dumping 23 channel units to make room for the 40 channel models. An amateur with only basic skills should be able to buy and convert a 23 channel CB unit to 10 meters for less than $80 – of course, if the unit chosen for conversion is more exotic and costs more to begin with, the total price can be much higher.

Our primary reason for choosing the 123A over other models was simple . . . we had an extra one gathering dust on the shelf. We could have used practically any unit on the market, and so can

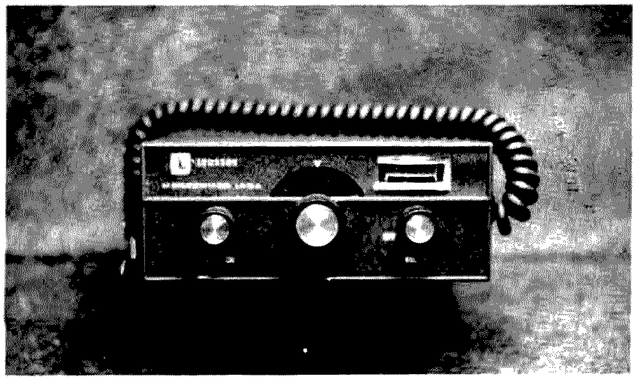

Fig. 1. No, it's not another CB. It's a hot little 10 meter conversion.

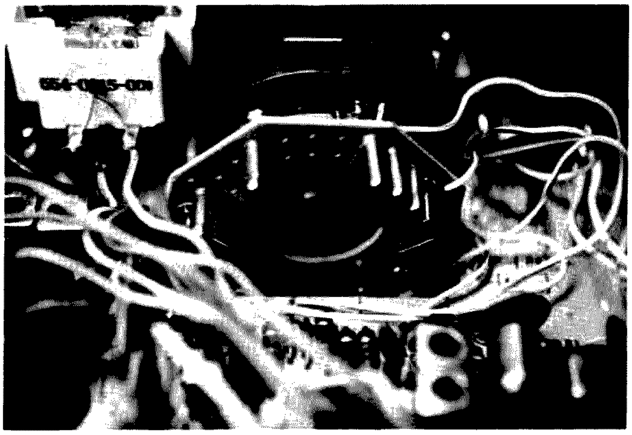

Fig. 2. The crystal bank PCB should be removed for easy access to the crystals.

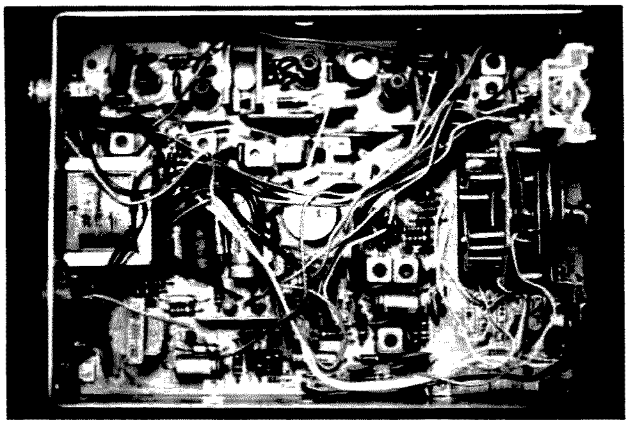

Fig. 3. Interior shot of the 123A showing the transmitter strip at the top.

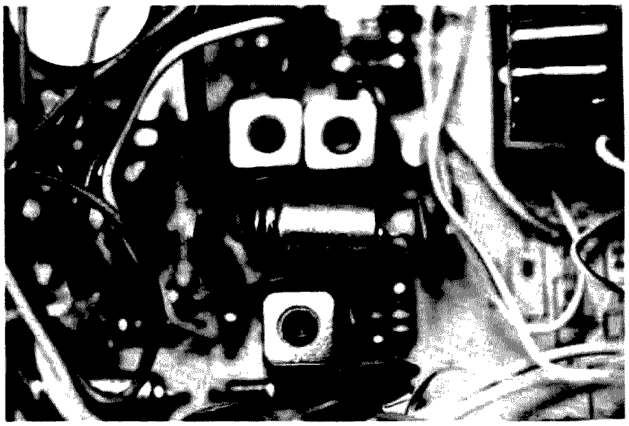

Fig. 4. Detail of the oscillator synthesizer mixer tuning adjustments and test points.

you. However, let's go through this particular conversion step-by-step, since most conversions will differ only in minor details. If you follow what we did here, you should have no trouble with other makes or models.

The 123A is a single-conversion synthesized unit using a channel frequency minus 455 kHz input to the receiver mixer. This is accomplished by mixing the output from a high frequency oscillator with that of a low frequency oscillator and using the difference frequency.

For example, when the unit is tuned to CB channel 1 (26.965 MHz), the high frequency oscillator operates at 32.700 MHz. The low frequency oscillator on channel 1 operates at 6.190 MHz. The difference frequency is 26.510 MHz, which is 0.455 MHz below the channel frequency.

When the unit is switched to the transmit mode – still on channel 1 – the high frequency oscillator continues to operate at 32.700 MHz, but the low frequency oscillator has a 5.735 MHz crystal switched into the circuit and the 6.190 MHz crystal is switched out. This new difference frequency – 26.965 MHz (same as the channel frequency) – is simultaneously switched to the transmitter strip, and the receiver is muted.

While the 123A is a 23 channel unit and only uses 14 crystals in all, each crystal must control several channels. If you start at the lower end of the band (channel 1) and change channels all the way to the top (channel 23), you will find that the high frequency crystals are switched after four consecutive channels and the low frequency crystals are switched for each channel and repeat every fourth channel. Table 1 should make that clearer.

We decided that since we had to start somewhere, a frequency jump of exactly 2 MHz would simplify matters, so that is what we used. It would have been as good from an operating standpoint to shift the low frequency crystals, but for economy we decided that it made much more sense to change only six crystals rather than eight. (Another reason to use the higher oscillator for changes is that low frequency oscillators are sometimes pretty narrow banded. We didn't want to have to change any tuning components if we didn't have to do so.)

By referring to Table 1, you can see that to raise receiver and transmitter frequencies 2 MHz, you simply raise the high frequency oscillator 2 MHz. The new difference frequencies (28.965, etc.) fall into the 10 meter phone band.

We ordered the new crystals and put the unit back on the shelf until they arrived. When they finally got in after several weeks, we took the unit out of the case and began the conversion.

Removing the crystal bank – it surrounds the channel selector switch – in the 123A is a relatively simple matter of taking off the front panel knobs, the four screws which secure the front panel to the chassis, and the two tiny bolts which fasten the crystal bank to the channel selector switch. In Fig. 2 you can see one of the nuts which holds the crystal bank located at the left center of the picture.

When the fiber PCB which holds the crystals is loose, it is a simple matter to remove the high frequency oscillator crystals and replace them with the new crystals. Use a good clean iron for the job in order to minimize damage to the PCB.

When all of the new crystals are soldered in place and the leads trimmed, reassemble the whole mess and you are ready to start tuning.

Tuning can be very simple if you have the right equipment. If you don't, we would suggest that you borrow it. In this case the right equipment is a diddlestick and an rf VTVM.

Look at Fig. 3. Slightly to the right and below center you can see two tiny transformers. Below them you will see one more. The lower transformer sitting all by itself is T7. Transformer T7 tunes the output of the high frequency oscillator.

Fig. 4 is an expanded view of T7 and its associated components. Just to the right of T8 and T9 is transistor Q14, the synthesizer mixer. The output from the high frequency oscillator is coupled through T7 to the emitter of Q14. With the unit in the receive mode, connect the rf probe to the emitter of Q14 and tune T7 for maximum. The reading should be somewhere between 0.5 and 1.0 volts rms of rf. After you have tuned T7 for maximum, switch through all of the channels. If you are measuring the right output, after every four channels the reading will momentarily dip as you switch in another crystal. When you turn the channel selector to the blank space between channels 22 and 23, the reading should go to zilch In this unit, as in many others, the channel selector switch has a cutout to prevent operation in this position. (It used to be called channel 22a, 27.235 MHz, which was illegal under the old CB rules.)

After you are satisfied that the oscillator is working properly, move the rf probe to the diodes to the left of the filter capacitor directly above T7. The cathodes of these two diodes are connected, and this is your next test point. Tune T8 and T9 for maximum at this point. You may have to go back and touch up T7 as you load it by tuning T8 and T9.

If you get something between 0.3 and 0.5 volts rf at this test point, it is downhill all the way from here. If not, go back and start over again at T7.

In Fig. 3 you can see two small transformers above the channel selector. These are T10 and T11. To tune them, connect the rf probe to the collector of rf pre-driver Q15 (in Fig. 3 Q15 is obscured by the mike cord, but it is the first transistor in the transmitter strip and is close to T10/T1). When the probe is connected, connect a dummy load to the rf output of the unit and key the mike. The rf output measured on the collector of Q15 should be several volts. If you have it, move the probe to the next transistor in the transmitter strip and tune each stage for maximum before going on to the next. By this time, you should have a Watt or two of rf at the transmitter's output, and you can complete tuning with a wattmeter if you have one – and you either do or have a friend who does.

Before you do any receiver tuning, complete the transmitter tuning. When you are finished, you should have 3.0 Watts or more at 13.6 volts dc input. Transformers T10/T11 may need to be stagger-tuned to optimize output on all channels. All other transmitter tuning should be done at or near the center of the band (channel 12 or 13). After you have maximum output, whistle into the mike. The wattmeter will probably kick down. If you have tuned to maximum, you may be showing as much as 5.0 Watts of output. The 123A will usually not modulate that much power fully and transmitter tuning should be touched up a little.

Between the rf final amplifier and the output connection you can see two tuning coils. After the unit has been tuned to maximum, insert a diddlestick into the coil nearest the final amplifier. Using short whistles, turn the slug clockwise into the coil until the wattmeter begins to kick up slightly on the peaks. Then go to the last tuning coil and retune it for maximum output. Do this back and forth until you have the maximum output which will allow the wattmeter to show a slight kick upwards on peaks. If this point happens to be in excess of 5 Watts, fine. If it is less – and it probably will be – that's okay too. In any event, that point is where the unit should operate for cleanest, best modulated output.

Now you are ready to tune the receiver section. Assuming that the unit was working properly on CB frequencies, you have only two minor adjustments to make.

Look at Fig. 3 again. Directly below and parallel to the transmitter strip is the receiver rf and i-f strip. Don't disturb any adjustments except those of the two cans closest to the rear of the chassis. The can sitting by itself near the modulation transformer is T1, the receiver rf input tuning. The next can in the line is the mixer input tuning, T2. There are two easy ways of tuning these two cans.

If you have a stable signal source and can be certain that it is on frequency, set it for 29.085 MHz (new channel 11-10m), couple it to the transceiver and tune for maximum output or S-meter reading.

The other way is to connect the unit to an antenna which exhibits a low vswr on 10 meters and tune for maximum noise. Normal precautions against tuning to an image frequency should be observed. As a general rule, if you tune to the first peak that you come to from the original positions, you will be right on the money the first time. Measure the output frequencies with a counter, check it out with a friend across town, and you are on the air. Total time involved? A couple of hours.

In our prototype unit, we noticed only one unusual item. On channel 4-10m (you have to call them something), we have a relatively strong received signal present even when the antenna is not connected. Since we have 22 other channels to use, we decided to forget it and not go looking for spurs. The same problem may or may not show up on your conversion.

As mentioned before, we chose this unit simply because we had it. If you have another make or model, your conversion may be a little harder. If the crystals are of the plug-in type, the conversion may be easier. When you begin to tune the unit, take it one step at the time. Few if any CB units will operate at a new frequency without careful retuning.

The 2 MHz jump seems to be a good idea to us. Channelization means that mobile operation is simple and fiddle-proof. As a suggestion, it seems to us that channel 1-10m (29.965 MHz) would be a good calling channel. If everyone who makes a +2 MHz conversion monitors this channel as the band opens this summer and fall, there should be a good chance of making contacts. If everyone jumps around all over the band, the chances go way down. Be seeing you on 10. ■

CHANNEL	HF CRYSTAL	RECEIVE LF CRYSTAL	RECEIVE OUTPUT	TRANSMIT LF CRYSTAL	TRANSMIT OUTPUT
1	32.700	6.190	26.510	5.735	26.965

CB to 10

-- part V:

converting the Hy-Gain 670B

As a result of the recent dump of 23 channel Citizens Band radios on the market in anticipation of a big push for the new 40 channel units, there are many 23 channel units at real bargain prices. I paid $40.00 for the one I purchased, a Hy-Gain 670B (Hy-range I). The radio that I bought lends itself very handily to conversion to the 10 meter ham band. The Hy-range I is a 23 channel, synthesized, 4 Watt output, AM radio. If you choose another type radio make sure you get one that uses crystals, not phase locked loop. The newer types with the synthesizer lend themselves to conversion better than the older types that use one crystal for transmit and one for receive. With the newer units you get a lot more useable channels for a lot less cost.

Looking at the schematic that came with the radio, I located the bandswitch and the oscillator crystals were next to it. The Hy-Gain schematic has a chart that shows the crystals required to synthesize the unit. What you want to do is to change the smallest number of crystals possible due to the cost factor. I decided to use the 4 crystals in the 14 MHz oscillator section and leave the 23 MHz section alone as it contains 6 crystals. It may be possible to change only the offset oscillator crystals, in this case, 11.275 and 11.730 MHz. I did not try this as I believed that the coils in the front end of the receiver and in the transmitter would probably tune the proper range without modification. This proved correct. The i-f section may or may not tune. I'll leave that to someone else to try together with the chance of blowing the price of a couple of crystals.

The crystal needed for the Hy-Gain is determined as follows: Channel 1 is to be 29.000 MHz. The 23 MHz oscillator frequency is subtracted from 29.000 MHz. Then the offset oscillator frequency of 11.730 MHz is added to that figure giving the required frequency, in this case 17.440 MHz.

With one crystal then, I set my radio up on 6 channels which came out this way:

Channel 1 . . . 29.000 MHz
Channel 5 . . . 29.050 MHz
Channel 9 . . . 29.100 MHz
Channel 13 . . . 29.150 MHz
Channel 18 . . . 29.210 MHz
Channel 22 . . . 29.260 MHz

I felt that 6 channels were enough to start off with. The other channels will no longer transmit after the coils have been retuned, thus any possibility of transmission of unwanted frequencies will be avoided in case the channel selector happens to get off on a channel that is not set up on 10 meters.

In order to make it simple to keep track of what frequencies are combining to form the desired frequencies, I made up a chart giving all of the frequencies involved.

When you order a crystal, be sure and give all the in-

Channel	11 Meters	10 Meters	23 MHz	Old 14 MHz	New 17 MHz
1	26.965	29.000	23.290	14.950	17.440
2	26.975	29.010	23.290	14.960	17.450
3	26.985	29.020	23.290	14.970	17.460
4	27.005	29.040	23.290	14.990	17.480
5	27.015	29.050	23.340	14.950	17.440
6	27.025	29.060	23.340	14.960	17.450
7	27.035	29.070	23.340	14.970	17.460
8	27.055	29.090	23.340	14.990	17.480
9	27.065	29.100	23.390	14.950	17.440

12	27.105	29.140	23.390	14.990	17.480
13	27.115	29.150	23.440	14.950	17.440
14	27.125	29.160	23.440	14.960	17.450
15	27.135	29.170	23.440	14.970	17.460
16	27.155	29.190	23.440	14.990	17.480
17	27.165	29.200	23.490	14.950	17.440
18	27.175	29.210	23.490	14.960	17.450
19	27.185	29.220	23.490	14.970	17.460
20	27.205	29.240	23.490	14.990	17.480
21	27.215	29.250	23.540	14.950	17.440
22	27.225	29.260	23.540	14.960	17.450
23	27.255	29.290	23.640	14.990	17.480

Fig. 1.

formation on your radio along with the frequency wanted. The Hy-Gain takes a 4342743 CS 26C 47 pF (International Crystal Co.).

Conversion

After taking the covers off, locate the 14 MHz oscillator section. This is the 4 crystals grouped together with their designation printed on the chassis. Locate X7 (14.950 MHz) and unsolder. Replace it with the 17.440 MHz crystal. Tune L2 and L3 down two full turns. Also tune L4 and L5 down two full turns. By now you should be seeing some output on a wattmeter or use the meter on the front of the radio. Tune the pre-drivers, driver and rf power amplifier for maximum output, in my case I easily got 6 Watts. It is important to tune L2 and L3, L4 and L5 in or down in the coil so that the synthesizer will end up with the sum (40.730 MHz) rather than the difference as I did at first.

For the receiver section, the coils to be tuned down two turns are L10 and L11. L12, L13, and L14 go only about one turn down. Using an external signal source on 29.000 MHz, apply a signal until the S-meter gives an indication, then peak the coils for maximum. The final sensitivity was as good as the manufacturer's specifications on the 27 MHz band.

The possibilities are numerous that these converted units can be put to. Inexpensive walkie-talkies can be converted. How about hidden transmitter hunts? CB antennas can be easily converted by reducing the length a couple of inches. The radio only draws about 100 mils when in a squelched condition, so it could be left on in order to catch band openings or local calls. So how about it fellows? Let's use all that space on 10 meters! Will be monitoring Channel 1 . . . (29.000 MHz) . . . see you on 10! ■

World's Smallest Continuity Tester

-- it's almost minute

Using a rubber-type two-pronged plug, the few components that make up this tester are mounted inside the plug. The hole in the end of the plug through which the cord enters is used for the NE-2 neon bulb.

Two small holes opposite each other are made near the base of the plug for the probe wires to extend, and the two 100k, ½ Watt resistors within the plug cavity, being in series with the probe cords, prevent shock. A piece of 5/8 inch i.d. aluminum tubing ½ inch long, placed over the bulb end of the plug, with a 5/8 inch o.d. clear plastic lens pressed into the tube, protects the bulb and enhances the appearance of the miniscule tester. Make the probe wires long enough to suit your needs. ■

New Products

from page 38

VHF ENGINEERING PROFILE

Most hams into VHF experimenting are familiar with VHF Engineering products. The ubiquitous "RX" and "TX" receiver/transmitter strips have probably been responsible for getting more amateurs on VHF FM than any other series of products. VHF Engineering is an amateur success story.

The company was founded in a basement by Robert Brown W2EDN early in 1972. Brown's philosophy was based upon mass buying of components: Why not provide an inexpensive kit whose parts individually purchased would otherwise be overly expensive? The idea worked, and the small company soon expanded. To date, over 10,000 TX transmitter kits have been sold. An original product line of three devices has expanded to over 130.

VHF Engineering is now located on Water Street in Binghamton NY, the former site of McIntosh Labs, a manufacturer of quality high-fidelity gear. Most of VHF's business is amateur-related (about 70%), although the company also has military and civil contracts. Brown and Marv Druskoff K2VIV have designed most of the company's products. All of the pre-built VHF products are hand soldered and tested, as the company is not involved in high volume production. The company is actually a subsidiary of Brownian Electronics Corp., which is owned by Brown and William Kupfrian. They are presently projecting sales of over $1 million in the near future.

A look at VHF's product line will provide an insight into Brownian's success. The popular receiver and transmitter strips are multi-purpose devices that are the basis for many other products. The TX and RX strips are available for all VHF bands, and are also used in the company's handheld transceivers and repeaters. Those repeaters are another story! VHF Engineering can provide complete repeater installations or any part of one, based upon customer requirements. Each module is available as a kit or pre-assembled, allowing complete flexibility in designing individual stations. The experience gained in repeater design has been valuable, as Brownian plans upon entering the two-way commercial marketplace in the future.

The product line also contains a wide range of power supplies and VHF/UHF power amplifiers, along with the most recent addition, a digital frequency synthesizer. The "building-block" concept allows the ham to select whatever components fit his operating environment, all the way from power supply to final amplifier. VHF's latest line of power amplifiers is the Blue Line series, which are designed for high power UHF applications. Of course, the amplifier can be driven by a VHF Engineering TX strip! VHF also provides a complete line of accessories such as crystal decks, tone encoders, and cables.

Many hams would probably not be on the VHF bands had it not been for Brown's basement operation. The company is constantly expanding, and only time will tell what new devices from Binghamton will arise to excite today's VHF/UHF amateur.

NEW WIRE DISPENSER ALSO CUTS AND STRIPS

The new WD series wire dispenser features unique cutting and stripping capability. Wire is drawn out of dispenser to the required length. Then, a built-in plunger cuts the length free from the roll, while a gentle pull through the stripping blade removes the insulation without nicking the wire. Repeating procedure removes insulation from second end. Although designed particularly for wire-wrapping, the inexpensive dispenser is ideal for many applications. The dispenser includes a 50 ft. (15m) roll of AWG 30 (0.25mm), top industrial quality, Kynar™-insulated, OFHC silver-plated solid copper wire. Insulation is offered in blue, white, yellow or red. Available from your local electronics distributor or directly from *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.*

NEW CATALOG COVERS LIGHT EMITTING DIODE (LED) DISPLAYS

National Semiconductor has prepared a full-color short form catalog detailing its complete line of optoelectronic products. The catalog contains photographs, outline drawings, and specifications of National's red, yellow, and green light emitting diode (LED) lamps, large area (0.3", 0.5" and 0.7" high) multi-digit numeric displays, small calculator-type numeric arrays, and watch display die. *National Semiconductor Corporation, 2900 Semiconductor Drive, Santa Clara CA 95051.*

NEW CONTINENTAL SPECIALTIES CATALOG

Continental Specialties Corporation, manufacturers of breadboarding and test equipment for the professional and hobbyist, announces the release of their new 1977 catalog. This 16-page catalog features the complete line of Continental Specialties QT sockets, proto-clips, protoboards, logic probes, logic monitors and design mates, and introduces the new Experimentor sockets.

Catalogs are available from — *Continental Specialties Corporation, 44 Kendall Street, PO Box 1942, New Haven CT 06509.*

Open New Frontiers!

-- VHF sideband

I heard some "lowbanders" (HF types) chatting away the other day about some "crazy VHFer in Santa Cruz" (not me, by the way) who claimed to work Los Angeles, Fresno, and the like . . . even some mobiles out to about 150 miles on *two meters*!

The other fellow said, "Ah, sure. It's them repeaters, you know."

"Nope," replied the first. "This guy was using one of those little three Watt rice box rigs on *sideband direct* . . . not on any repeater, so he *says*!"

"Oh," replied number two. "Well, everyone knows those VHF SSB types are liars!"

Where's the Fun Gone?

I'm not so old and I haven't been in ham radio for much more than a dozen years, but it seems that some of the fun has gone out of the hobby for many people. Maybe it's because of the loss of so much of the "new blood" to CB, leaving us devoid of the enthusiasm generated by newcomers to the hobby. Maybe it's because of the rich man's war that has made 20 and 40 meter beams and kilowatts *required* equipment nowadays rather than luxuries. Maybe it's because unless you really dig CW (which can be operated with a minimum of cash outlay) or really like to stand in line on the local repeater for 25 minutes in order to get your *very own* three minutes (down to one minute on some machines around here), then you're either going to have to lay out a few kilobucks for gear or buy some ancient metal monster that's *already* been used for a boat anchor. The latter is not any more likely to make "brownie points" with the wife than the former!

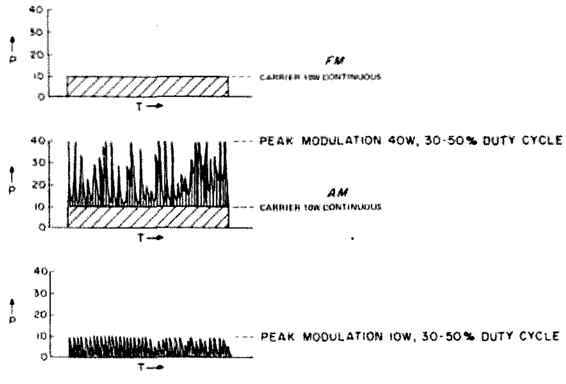

Fig. 1. Average power.

Frankly, when I got back on two meters after a few years' absence due to higher education, I wasn't enthralled by what I heard. True, to each his own, but I couldn't quite relate to tone bursts and 25 minute waiting lines on the local repeaters. I also balked at the four page lists of "dos" and "don'ts" that were being handed out by some repeater groups. Of course, the $20 initiation fee and $10 yearly assessment was a bit beyond my meager student income, too. So I stuck to the small but still active group of AMers left on the band.

Unfortunately, when I moved from the Bay Area to Santa Cruz, the 3000 foot mountains put a real dent in my signal. Though I could hear the boys across the hills on my receiver/converter combination, they had trouble picking me out of the noise on their Communicators and the like. If only those two meter AM rigs modulated like CB sets, had noise limiters, and good sensitivity!

At the time, two meter SSB was a once-a-week, Tuesday night net thing with about 15 active stations. However, I found a two meter single sideband transceiver (so it said on the label) made by Belcom so I put the thing on the air and made some noise! Having worked all the then-active SF Bay Area stations and finding the rig a nice package, I took it up to the SRI VHF/UHF Society meeting to a show-and-tell session and showed it off. Bruce Clark K6JYO scanned it with interest and shot off for home shortly after the meeting so that he could work me mobile all the way home to Santa Cruz . . . some 45 miles through those 3000 foot mountains. After this successful test, Bruce got KLM interested in the unit and the rest is history!

Why Single Sideband?

This isn't a question that's asked on the HF bands much any more, where sideband's advantages in a crowded band and for DX are obvious. On VHF there are fewer people who have been exposed to its advantages.

Single sideband has the same advantages on VHF that it has on the HF bands. It requires low average power drain for a given effective power, extends PA life and reduces heat sink requirements due to lower *average* power dissipation, reduces multipath and phase distortion, increases potential sensitivity by reducing required bandwidth, allows break-in operation, and provides excellent weak signal recovery.

These last two features have been responsible for the increase in medium range "DX" contacts on two meters in recent years. With increased activity, weak signals are often heard between syllables during a local QSO (something not possible with FM), and though the signal may not be copyable, with SSB *something* can be heard

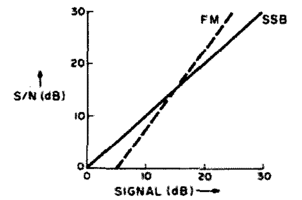

Fig. 2. Weak signal effectiveness. FM s/n is better than SSB above *10 dB s/n, but SSB is superior on weak signals below 10 dB s/n. This makes SSB better able to find and copy weak DX stations.*

and beams be brought around to peak up the station – or the old VHF wait-for-the peak game can begin.

Sideband Working Distance

In everyday terms, sideband extends the radio horizon 50% to 100%. In hilly terrain where multipath is a problem, sideband's advantage over FM can be even greater than 100%!

Here in hilly California, repeaters have a typical working range of 50-150 miles radius. Ten Watt sideband stations typically run equal range *and better* with higher powered stations (50-150 W), getting frequent contacts out to three or four hundred miles.

It is not uncommon, for example, for Santa Clara Valley stations running 10-20 W to work into Los Angeles on a good night. Well located, high powered stations like Mike Stahl of KLM or Jay Shaffer W6BWB can work LA and San Diego almost any time of day or night!

Special Modes

In addition to regular point-to-point communication, there *is* one repeater on two meters (though sidebanders prefer the term "translator") that is used quite extensively throughout the United States. It has a beautiful location about 1000 *miles* above sea level and has a working radius of some *2500 miles*! Oscar VI and more recently Oscar VII provide a fascinating means of SSB and CW contacts for anyone with a Technician class license or higher.

From the East Coast, Britain and Western Europe can be worked via Oscar. Canada and Mexico, Central and parts of South America can be worked throughout the U.S. Japan and the Pacific are available to West Coast hams.

Getting Started

There are several approaches to VHF SSB. The easiest for the HF operator with a rig having a low power transverter output is to buy the transverter made for his rig.

Those who prefer not to tie up their HF rig when they get on VHF SSB may prefer one of the separate transceivers available.

Those who already operate two meter FM may want to trade up to one of the AM/FM/SSB/CW multimode rigs now available.

The following listing gives a brief overview of what's available, including some general remarks about the strengths and weaknesses of each rig.

THE KLM ECHO II

The KLM Echo II was the first two meter transceiver available (discounting the Gonset Sidewinder from several years back). It is totally solid state and runs off 11-15 V dc (no built-in ac supply). It is conveniently mobile, measuring only 2.5 x 8.5 x 10 inches, and has squelch (the only unit that does on SSB), an effective noise blanker, and excellent stability (crystal control with a VXO and RIT).

Specifications

Sensitivity: under .18 uV typical*;
Selectivity: 2.1 kHz @ 6 dB, 4.2 kHz @ 50 dB typical*;
Af Output: 3 W into 4 Ohms @ 10% THD;
Rf Output: 10 W PEP typical @ -22 dB 3rd order distortion*;
Spurious: -55 dB typical*;
Harmonics: -60 dB typical*;
Af Response: 150-2250 Hz typical*;
Features: S/RFO meter, Crystalplexed synthesizer with VXO (±6 kHz) and RIT (±2.5 kHz receive only), squelch, noise blanker, ALC, vswr protection, semi break-in CW, bandswitch (up to 5 bands, 230 kHz each with 145-145.23 and 145.77-146 included), ext. key for linear, ext. spkr. jack, upper and lower sideband mod kit (for Oscar VII downlink), and accessory FET preamp (improves AGC action and gives .08 uV/12 dB SINAD or better);
Price: $390.

***Values marked with an asterisk are units that I have tested or had dealings with. Sensitivity = 12 dB SINAD. Tx IMD *referenced* to *each* tone. Spurs and harmonics references to PEP output.**

Pluses and Minuses

On the plus side, the Echo II is easy to service, has plenty of room available for modifications, and costs less than the multi-mode rigs. The only other SSB-only rig is only 3 W PEP and isn't easily modified for lower sideband for Oscar reception. The VXO allows good frequency control and resettability, so that finding frequencies for skeds is easy. Given two Echo IIs, if each moves up 30 kHz (three channels) they will end up within 100 Hz of each other. This is great for mobile where QSYing can be safely done by merely counting one channel for each 10 kHz *without looking* at the dial.

The major drawback with the receiver is the lack of AGC below 1 uV. This is quite bothersome when working strong locals with weak DX. The KLM preamp helps with this, as do other mods.

The transmitter is frequently accused of being "muffled" or "bassy." This can be helped by tuning the BFO frequency until a 400 Hz tone in the mike input drops to ½ W from a starting level of 2 W (6 dB). Of course, this drops the CW output quite a bit as well. Another approach is to find a mike with a natural roll-off below 1 kHz. (Note: A D-104 *doesn't* work unless its high output is transformer-coupled to the 500 Ohm Echo II input.)

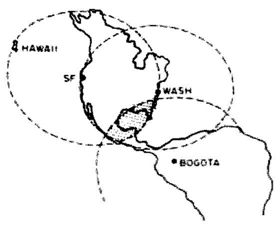

Fig. 3. Oscar working radios. Overlapping areas can work each other.

THE ICOM IC-202

The Icom IC-202 is SSB only. It is a "walkie-talkie" similiar in size to the TR-22 FM rig. About 2.5 x 6.5 x 7.5 inches, it has a built-in whip antenna in addition to its normal output jack. The unit covers 200 kHz with a VXO multiplied up from 14 MHz and calibrated in 5 kHz increments. There are positions for four crystals, with 144.0 and 144.2 MHz standard. Why Icom doesn't make 145 MHz one of the standard crystals, I have no idea, considering that it would about *double* their potential customers by adding the Technicians.

The receiver works quite well with a MOSFET/JFET front end which gives 70 dB intermod and crossmod rejection. AGC is reasonable . . . about 15 dB change from .3 uV to 1000 uV input change. Provision is made for an external VFO, although none is presently available.

Specifications

Sensitivity: under .125uV typical*;
Selectivity: 2.4 kHz/4.8 kHz (6 dB/60 dB), 70 dB ultimate;
Af Output: 1.0 Watt @ 10 THD into 4 Ohms*;
Rf Output: 3.2 W PEP typical @ -30 dB 3rd order distortion*;
Spurious: -60 dB or better (most below 70 dB*);
Harmonics: -60 dB or better;

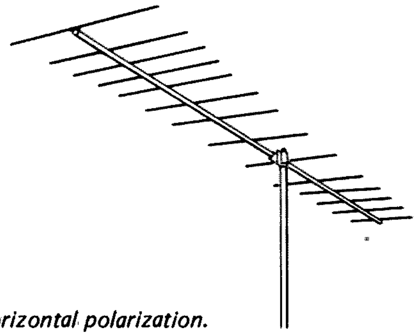

Fig. 4. Horizontal polarization.

Af Response: 500-2900 Hz typical*;
Features: S/RFO meter, 200 kHz VXO calibrated in 5 kHz steps, noise blanker, ALC, RIT with center off detent, CW/SSB switch, bandswitch (four bands, 144.0, 144.2 included), external speaker jack, VFO input jack, built-in battery compartment (uses nine "C" cells), carrying strap, pilot light/panel light on/off switch (to conserve power on batteries), built-in whip antenna;
Price: $280.

The **Good**, the Bad, and ...

The IC-202 comes with a very good, large size schematic in spite of the 202's small size. It is extremely portable and fun to take on trips or mountaintopping. Numerous 202s have shown up on the air in the Monterey Bay Area and San Francisco Bay Area while their owners were on vacation or on business in the area. It also is a natural for emergency and public service operation. The unit's range varies depending on terrain and location, but normally has good signals over 5-10 miles with marginal results as far as 25-30 miles. Mountaintoppers can expect 100 miles easy with the built-in whip — and more with a beam.

The 202's receiver is remarkably free from spurious, crossmod, and intermodulation problems. Under some conditions, the noise blanker will cause cross modulation by very strong in-band stations. Most of the time it does not, though. Its sensitivity is about what is needed for a 3 Watt rig, but can be improved. I suggest using a preamp of the FET type (*not* MOSFET), with about 10-15 dB gain mounted in the power amplifier box if one is added later. The J-310 or U-310 (Siliconix) are popular on the West Coast for this.

All 202s have a slight drift problem, especially if cheaper US crystals are used in the VXO. Some retuning in any ten minute period is often required, but it is by no means as bad as what we used to put up with on 2m AM several years back. Checks in the lab show about 500 Hz drift over a temperature range of -30 to +50 degrees Centigrade. Normal variations can then be expected to be 100-200 Hz at room temperature. (By the way, if your shack has the kind of temperature range we used in the lab, I suggest you install a heater in the place!)

The 1 Watt audio output is adequate for most applications. However, in noisier vehicles like my VW bus, the af output is marginal. A well placed external speaker would probably help.

The size of the IC-202 is both a blessing and a curse. Of course, it makes it very convenient for mobile operation, but it also makes it difficult to service or modify. This is why I suggest putting any preamps in the power amplifier instead of trying to put it inside. It also makes it difficult (probably impractical) to put lower sideband into the 202.

THE KENWOOD TV-502

The first transverter that became apparent on the market in the recent sideband boom was the Kenwood TV-502. It covers 144-146 in two bands, with the 144-145.7 range included normally (converting from 28.0-29.7 MHz). The transmitting section seems to be very clean sounding and puts out around 8 W PEP. The receiving converter lacks gain and noise figure, so that its sensitivity is only around .5 uV; an additional preamp is almost always necessary. There *is* room to build the preamp inside the unit. The 502 matches the Kenwood HF line, of course. Price class ... $260.00.

YAESU

Yaesu also makes a transverter for their equipment, but none has shown up in this area as yet. Little information (specs, price, etc.) is given in the ads by Yaesu, but performance equivalent to the Kenwood seems likely, with a price to match. It seems that there is little effort on Yaesu's part to promote this unit, as they don't tell enough about it to get anyone interested in it!

THE EUROPA B

A different approach can be seen in the Europa B transverter ads. Through small ads by a small company, I can learn that the unit uses 5894s in the final with about 80 W PEP output, interfaces with the Yaesu line with no external power required, is 9 x 4-3/4 x 4-1/2 inches, has MOSFETs in the converter section, and requires about 100 mW of drive. It costs $299 ($279 without tubes).

THE KLM MULTI-2000

An early comer to two meter SSB was the ITC Multi-2000. Unfortunately, the small size of the importing company did not result in good enough quality control, and numbers of these multimode, synthesized rigs got out to the field with out-of-band spurs only 25-35 dB down! The FAA got upset, since these were falling on aviation frequencies, and the FCC "respectfully requested" some changes. Well, KLM was the change that came about. They bought out ITC's franchise for the Multi (made by FDK of Japan) and bought an HP Spectrum Analyzer so that *each unit* could be checked before going out. They also sent a test unit to the FCC, which gave it a clean bill of health. So now the Multi-2000 is one of the four multimode rigs on the market.

Specifications
Sensitivity: .1 uV typical (less if peaked for 1 MHz of the band)*;
Selectivity: 2.4 kHz;
Af Output: 2 Watts into 4 Ohms @ 10% THD;
Rf Output: around 10 W PEP;
Spurious: -55 to -60 dB or better;
Harmonics: -60 dB or better;
Af Response: 300-2700 Hz;
Features: S/RFO meter, digital synthesizer with 10 kHz steps across the entire 2m band, VXO (±10 kHz), RIT (±5 kHz), noise blanker, ALC, CW/AM/FM/SSB, upper and lower SSB, ext. key for linear, ext. spkr. jack, wideband and narrowband FM, 600 kHz up or down or simplex, three crystal channels, FM squelch, FM 1 W or 10 W position, rf gain control, ac and dc power supplies built in.

Strengths and Weaknesses

Unlike the other multimode rigs, the Multi-2000 features a PLL synthesized 10 kHz step frequency control, which makes frequency setting for FM (and SSB, for that matter) very easy. Each click is ten kHz, making mobile operation safer by not requiring the operator to tune by a meter or VFO, etc. Of course, there are times when the VFO is better, as when operating SSB. However, the VXO and RIT allow good flexibility here, too.

The Multi's AGC has had some problems according to some users. It's not as bad as

the Echo II, but perhaps not quite as good as the FT-221 or TS-700. I get an impression from off-the-air comments that the difference is slight, however.

As previously mentioned, the early Multi's had out-of-band spurious problems with a vengeance. This has been cured by KLM's quality control.

Some feel that the Multi-2000's transmit audio is not quite as good as the other multimode units. While I agree that it usually does not sound as "hi-fi," I think that I have heard about as many FT-221s and TS-700s with bad audio as Multi's. A *good* 221 or 700 sounds very good, but a bad one sounds really bad.

THE KLM MULTI-2700

Another entry in the multimode market is the KLM Multi-2700. This rig has a stiff $800 price tag, but it has some unique features, too. These include a VFO *or* PLL 10 kHz per step synthesizer, converter built in to receive the 10m Oscar downlink with reception tracking the two meter transmitter, VOX, LED readout, and user programmable FM repeater splits in addition to the normal ±600 kHz splits.

Specifications
Sensitivity: .1 uV;
Selectivity: 2.4 kHz;
Af Output: 2 W into 4 Ohms @ 10% THD;
Rf Output: 10 W PEP (10 W or 1 W FM);
Spurious: -60 dB or better;
Harmonics: -60 dB or better;
Af Response: 400-2800 Hz;
Features: S/RFO meter, PLL 10 kHz step synthesizer *or* VFO, VXO, RIT, CW/FM/SSB, upper and lower SSB, noise blanker, ALC, ext. key for linear, ext. spkr. jack, FM squelch, built-in ac and dc supply (incl. 220 V European standard with 115 V ac and 14 V dc), space for 50 MHz or 432 MHz converters, LED readout, tracking converter for Oscar 10m downlink (but cannot receive while transmitting), 600 kHz up/down split or user programmed, built-in VOX.

As this unit is barely introduced as I write this, little is known of its performance. Listening to this unit, I noted that it is clean, but not "hi-fi." The Oscar feature is nice. One drawback is that the 10m downlink can't be monitored while transmitting, since the unit is a transceiver having a common i-f. The RIT can be used to approximate the Doppler shift, but this is imprecise, to put it mildly! It is still quite usable in this mode, even if not as convenient as a separate receiver.

THE YAESU FT-221

As soon as it hit the market, the FT-221 was a success. By preceding the TS-700 by a few weeks and by being more readily available in stock early in the game, the 221 has enjoyed a great deal more popularity in *this* area than the TS-700. One frequently mentioned reason is the modularized construction the rig sports. Cosmetic-wise, the two are essentially similar, but the 221 has its circuits on vertically-mounted cards, providing good isolation and ease of replacement. The theory goes that service is easier, too. If you happen to have a substitute board, I suppose this is true, but unless you have extender boards (not supplied), service of a "live" circuit is out of the question! So, it's six-of-one-and-half-a-dozen-of-the-other.

Specifications
Sensitivity: .2 uV or less on SSB;
Selectivity: 2.4 kHz/4.1 kHz 6/60 dB;
Af Output: 2 Watts into 4 Ohms @ 10% THD;
Rf Output: 12 W PEP nominal (14-16 W typical, 18 W on FM);
Spurious: -60 dB;
Harmonics: -60 dB;
Af Response: 300-2700 Hz;
Features: S/RFO/FM tuning meter, phase locked VFO covering all of two meters in 500 kHz bands, 1 kHz readout, AM (2 W), FM, CW, SSB, upper and lower SSB, noise blanker, ALC, ext. spkr. jack, FM squelch, ac and dc power supplies, tx/rx or rx only clarifier.

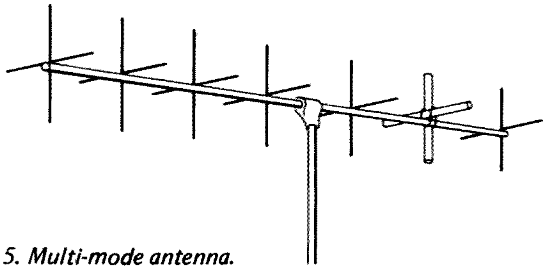

Fig. 5. Multi-mode antenna.

Bouquets and Brickbats

The only real problem that has been noted on the FT-221 is that the gain setting for FM and SSB on the mike gain control is not the same. With normal FM mike gains, SSB tends to overdo it a bit, causing distortion. Since this level is front panel controlled, no problem should exist once proper levels are established for the two modes.

Even with proper settings, some FT-221s have bassy and mushy audio. Most units are very clean and good sounding, but *some* have this problem.

Some 221s have lacked sensitivity. Most are good, but *some* seem to get through Yaesu's quality control department.

On the plus side, most 221 owners are quite happy with the units on both SSB and FM. Good ones sound *very good*.

THE KENWOOD TS-700A

Kenwood's TS-700A is similar in function and performance to the FT-221. It also features full coverage of two meters in 500 kHz segments (VFO) and has AM/FM/SSB/CW. Styling is also similar. One notable difference is that the 700 has final load and drive controls, making its operation less "hands-off" than the Multi-2000 or FT-221. I'm told by users that these controls are very broad, requiring little adjustment over a given band segment, however.

Specifications
Sensitivity: .1 uV/12 dB SINAD;
Selectivity: 2.4 kHz/4.8 kHz @ 6/60 dB;
Af Output: 2 Watts into 4 Ohms @ 10% THD;
Rf Output: 10 W PEP, 3 W AM;
Spurious: -60 dB;
Harmonics: -60 dB;
Af Response: 400-2600 Hz (published);
Features: S/RFO meter, FM tuning meter, PLL VFO in 500 kHz bands across 144-148 MHz, 1 kHz readout, AM/FM/SSB/CW, upper and lower SSB, noise blanker, ALC, ext. spkr. jack, FM squelch, built-in ac/dc power supply tx/rx or rx only clarifier;
Price: Around $700.

Ups and Downs

Most sound very good on the air, with a resonant "broadcast quality" tone. The tone is not necessarily "natural," however, and under weak signal conditions *some* voices do not "punch through" too well. Adjustment could be made by microphone choice or BFO frequency shift, if desired.

Most comments of TS-700 owners parallel those of FT-221 owners. The AGC in both cases is reasonable, but not as good as might be desired for working DX and locals simultaneously. A preamp could be useful, especially if a linear is added to the system (j-310, or equivalent).

Which Way To Go?

As you can see, the options for two meter side-

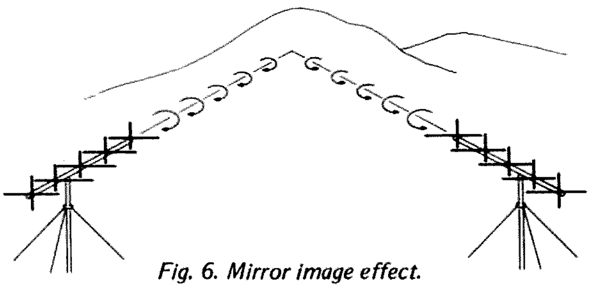

Fig. 6. Mirror image effect.

band have rapidly expanded in the past two years. Since KLM broke the waters with the Echo II, sideband has been growing very rapidly, with several manufacturers jumping on the bandwagon. Your final choice should be based on your operating habits and taste. But don't let your *current* operating habits have too much influence, as you may decide to *change them* once you've been on sideband for a while!

Of course, the best thing is to compare units side by side. Unfortunately, not all stores stock all units, and their open hours are often not during peak operating hours. So you may have to socialize a bit and find someone who has the unit(s) you are interested in and give him a visit. This is a good bet, anyway, since he can give you an idea of the idiosyncrasies of the rig, along with its good points. He can also give you pointers on other aspects of setting up a VHF SSB station.

As far as one method of getting on over another ... transceiver or transverter, etc. ... it depends on your budget and needs. If you don't mind tying up the HF rig while operating VHF SSB, a transverter is an inexpensive way to get on. Consider, however, that unless your HF rig has a noise blanker, the transverter method suffers 6-20 dB degradation in performance on reception when ignition or other noise exists. It can also be annoying!

If you have FM and just want to add SSB with little additional outlay, the IC-202 or Echo II would look good. This also allows simultaneous monitoring of SSB and FM (which could be a plus in emergencies).

Full coverage and all modes are the attractive features of the 2000, 2700, 221, and 700 multi-mode rigs. Trading up to these rigs buys not only SSB but full frequency FM coverage as well!

Other Things

Of course, a beam antenna, horizontally polarized, is likely to be something you'll want to add. Vertical beams or ground planes and the like are good for repeater use, but the cross polarization is going to cost you 10-30 dB when you try to work SSB stations (all of which are horizontal except for newcomers). There's good reason behind horizontal. This polarization has less sensitivity to noise than vertical, and seems to have better consistency over long-haul paths. In 1963, several Santa Cruz VHFers experimented with WB6IZF in King City ... a path of about 100 miles. WA6YOG used an antenna rotatable in polarity from full vertical to full horizontal, as did IZF. Over a period of several months, horizontal showed better signal levels and less fading than vertical, and horizontal gave up to 6 dB improvement in noise rejection on the AM signals. Cross polarization showed 10-30 dB of loss, as would be expected.

As for what antenna to buy, your budget may be the limiting factor. Here in the West we are partial to the KLM line of antennas. Perhaps it's because Mike and Mel of KLM are quite active on 2m SSB out here, but it is also because their broadband, rugged antennas work exceptionally well. Many of the top moonbounce stations are using the KLM 12 or 14 element beams in their arrays, simply because they are made of heavy gauge aluminum. Since they cover the entire two meter band with low vswr and high gain, they are easy to stack without worrying about detuning one antenna with another close by.

On the other hand, the antennas made by CushCraft and Hy-Gain are also good, though made with lighter aluminum and narrower bandwidth (standard yagi) design. Their prices are very attractive compared to KLM's, being roughly one-half to two-thirds as much. *At resonance*, they can perform as well as the KLM units, but bandwidth will only be about one megacycle for 5 elements and around 500 kHz for long yagis. Stacking can be problematical beyond two antennas, as well.

One interesting consideration for owners of multi-mode rigs is the circularly polarized antennas that use only one feedline. These allow SSB and FM operation without switching antennas for vertical and horizontal polarization. KLM, CushCraft, and Hy-Gain all make them. KLM's cover all of two meters, but cannot have the polarity switched from left- to right-hand polarization. The others are normally cut with the vertical elements favoring 146-148 MHz and the horizontal elements favoring 144-146.

There is one caution to be noted here, though, and that is that two stations using circularly polarized antennas over a reflected path (bounced off a mountain, etc.) will end up cross polarized because of the "mirror image" effect. If one station is able to reverse his polarization (e.g., right-hand to left-hand), this problem can be eliminated. There is no such provision on the KLM antenna (KLM 16-C). The others show how it can be done, and since the elements are cut for opposite ends of the band, true CP doesn't really exist (it's more elliptical than circular).

Another caution is that CP causes a 3 dB drop in signal strength over the equivalent linearly polarized antenna, since half of the power goes to the vertical antenna and half to the horizontal. If working a horizontal station, he only receives the horizontal radiation. The same is true for vertical. Of course, when working another CP station, the 3 dB is *not* lost, and considering that 10-30 dB is lost by being *cross polarized* when using a vertical beam working a horizontally polarized station, the 3 dB loss is a good compromise!

So again, it boils down to your needs and choices. Five elements for SSB should be a minimum. Twelve or fourteen is typical. For Oscar satellite use, three or four elements, vertically polarized, tiled up from the horizon by about 30-40 degrees, work very well. Twenty-five to fifty foot antenna height is average, but higher antennas can give a decided advantage for stations shadowed by mountains close by. Figure about 6 dB every time you *double* the antenna height.

Be careful of cheap, CB-type coax. This stuff (sold by Radio Shack and others) has only partial shielding (recognizable by the loose weave of the shield) and is *not* good for two meters! It is lossy and may cause vswr problems.

Use a good grade Belden or Times Wire, RG-58 or RG-59, for runs up to 35-45 feet, total. Up to 100 foot runs, RG-8 or RG-11 is good. Above 100 feet, RG-17, though quite expensive, really pays off. Make sure the coax you use is the right impedance for your system. (58 and 8 are 50 Ohms, 59 and 11 are 75 Ohms.)

If you buy a cheaper antenna, make sure to trim it so that it is tuned for your

operating frequency. If you do this, you'll get optimum results and you'll have saved some money. If you don't, you may not be as happy as you would have been if you did.

Worrywarts of America

If that three minute timer's got you fretting about getting cut off in mid-sentence and you don't mind someone making nasty remarks under your five minute monologue (which you can do on sideband and everyone but the guy with the mike button pushed will hear it), get on board two meter sideband! We may sound like a bunch of higher class CBers on those occasions when our mood is less than sober (we like to have fun), but I dare say that most of our joking around would go right over the heads of the eleven meter crowd. You'll get *few* comments about your operating procedures on SSB (unless you're one of those who likes to run 15 kHz wide FM on the sideband frequencies . . . we *do* get unblessed by *some* things!). Not only that, but occasional "drop in" DX makes the band quite interesting. And when the marginal fringe (say, 150-250 miles) starts coming in like it was local, extended rag chews with stations you normally say "hello"/goodbye" to make for a community spirit.

Who knows? Someday *I* may even join an FM repeater group, but for now I'm enjoying myself too much on the lower end of two meters! Hope to meet *you* there someday! ■

Digital Synthesizer

-- revitalize old xmtr strips

David J. Brown W9CGI
RR 5 Box 39
Noblesville IN 46060

Have you ever wanted to either use that nice Motorola or GE tube type strip transmitter you have around because of the 25 to 30 Watt power it's nice to have for a base station, or noticed how cheap they are around the hamfests if you don't own one? This article is especially for you. It allows you to run that one or two frequency base rig, but on any frequency from 144 to 148 MHz (and higher for you MARS-CAP folks), every frequency, that is, in 10 kHz steps, or in 1 kHz and less steps, if you want to add more parts.

Not that this unit can't be used with the transistor type rigs – it can! If the transmitter requires 6, 12, or 18 MHz crystals, read on.

Some basic parameters were desired for the unit for use around the ham shack here. They were:

1. The unit should be "program" type in common switch combination, not tons of diode matrixes, rotary switches, etc. The ideal would be a decimal type thumbwheel switch having BCD outputs.

2. It should not require "coding," that is, the number you dial in should be identical to the frequency desired. No tables or charts.

3. It should use only cheap and easily available ICs, preferably TTL digital. This is my own hard core feeling of digital over PLL, analog, etc.

4. For my own requirement, it should be remote capable using only a single rf type cable to the transmitter strip. Multi-wire cables are both a problem and also can be quite costly for a 30 to 40 foot run like I have. When the EME rack went into the basement ham shack, the FM 3 band base rack had to go – upstairs to the back porch.

5. Comparison of desired and running frequencies must be done before modulation to avoid after lockup hunting.

6. Frequency derivation should have both the other bands in mind, the use of the Motorola "strip" transmitters because of their easy availability and maintenance (it is commercial grade gear), and

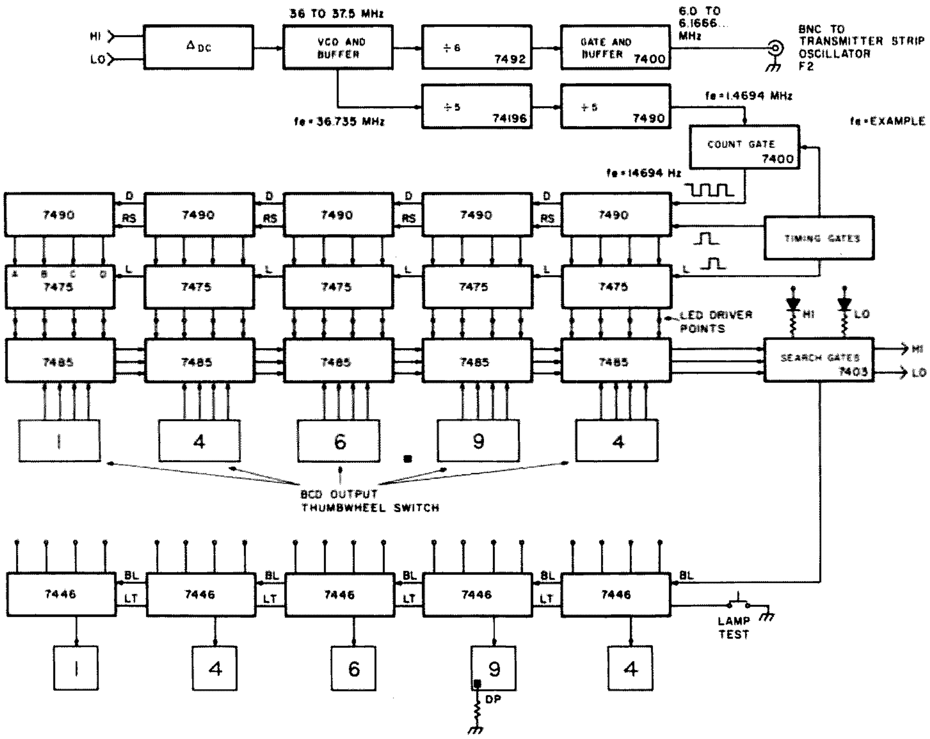

Fig. 1. Block diagram.

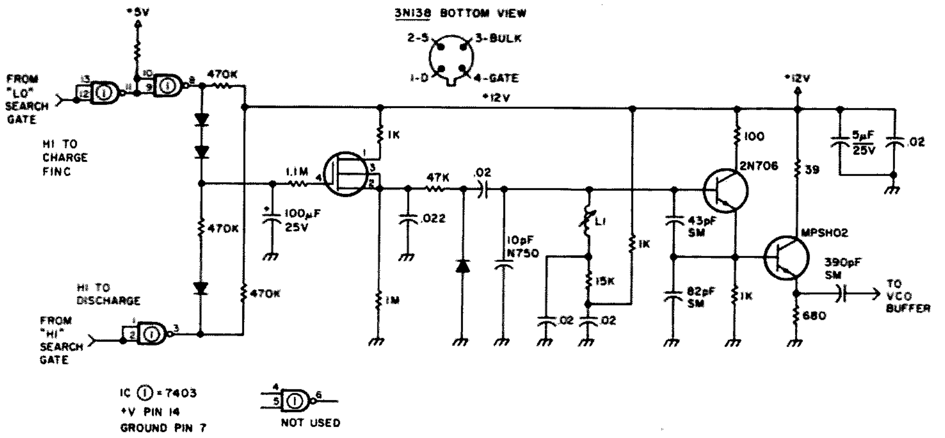

Fig. 2. VCO and "memory." L1=5½T #20 enam. ¼" form.

low cost now, and to do all this be of a divide nature (TTL) rather than multiplication type (discrete tuned circuits, bandwidth, etc.). The last requirement was going to be hard enough to do just getting the bandwidth out of the commercial strips – or so I thought.

I believe you will find it very beneficial to your success if you do things in a specific order on this project. If you already have the Motorola strip transmitter and a schematic and tune-up information on it, you are a long way along. If you have not already put it on some frequency on 2m, I suggest you do so and be sure it is all running right before you add this frequency unit. In fact, I would suggest you choose your favorite frequency and crystal up for it and leave it as F1. Then add an F2 deck modified to an amplifier as shown, so you have a backup if something fails, and a constant other normal oscillator source to compare to during the tune-up of the new unit. This way you can shift back and forth between the two sources to assure all is well during hookup.

The new unit works because it was designed very much for and around the unit it was intended to drive – the Motorola strip. Therefore, a word of introduction to that unit, and my apologies if I can't guarantee its perfect operation right off the bat with other units. The GE tube transmitter should be a very good substitute; however, I don't have one to try it on.

The strip used was a 30 W, single 2E26 final, 1 to 3 frequency model of the PA8664 chassis type. It requires an oscillator of 6.0 to 6.166– MHz for the output frequency to fall within the 144 to 148 MHz band. It should be noted and remembered these strip units are not broadband, and the 144 to 148 MHz figures are given for the new frequency unit's normal range. The transmitter should be peaked or stagger-tuned over the range you really intend to use (i.e., the 146 to 147 MHz range for me).

It should be pointed out that this is a digital VFO (VCO? – DVFO?) unit of sorts, and as such can be used with any number of tube type transmitters – FM or not!

One of the reasons this unit works is the very scheme that Motorola uses to get from the 6 MHz oscillator region to the 2m output (high band 150 to 174 MHz in their case). The multiplication scheme on these transmitters is oscillator times 24, but it happens as oscillator, doubler, tripler, doubler, doubler, to output. This is an important fact that is causing problems working out a similar scheme for the 6m and 450 MHz gear in the same cabinet. When you follow through the scheme I used, you will no doubt see what I mean.

The frequency unit runs a VCO oscillator in the 36 to 37.5 MHz range that is controlled the same as our "digital HFO" used on the EME BC-348s. Any VCO is dc controlled and our dc source is an FET-capacitor combination that has two separate and discrete electronic charge and discharge switches. Possibly the best part of using a dc controlled VCO is the fact that digital scanning, AFC, etc., can be added to these VCOs at a later date if desired. We don't want all this in the base FM station, but you will be able to see how it can be done as I manage to get the "Junque" series on BC-348s completed and turned in to *73 Magazine*. In fact, you will see a lot of the same circuitry used on a more than one item basis around here. This allows "modules" to be built, and repetitive results to be obtained time and time again.

Assuming the 36 MHz VCO works for the moment, let's carry that on out to the point it can run a transmitter. The VCO is quite capable, given the proper range, to run any 6m, 2m, or 450 MHz Motorola strip station. The dial in frequency comparison is where the hitch creeps in, so let's show how the VCO works on all first. The 2m transmitter, which I have mine running for, starts at the 36 MHz VCO and goes to a TTL gate and buffer to square up the VCO output for further TTL processing. From the buffer, in the transmitter chain direction, it goes to a divide by 6 TTL IC (7492) and has an output of 6.0 to 6.166– MHz. It is best to do the divide by 6 as a divide by 3, then divide by 2, for a symmetrical square wave output. The transmitter is usually narrow enough, and the feedline to transmitter

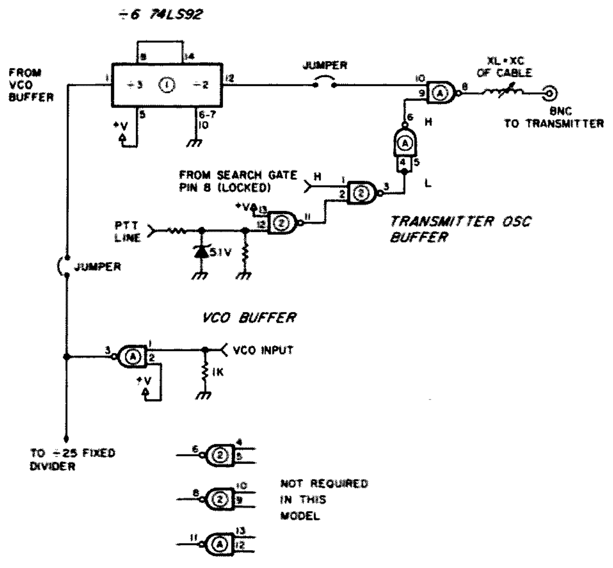

Fig. 3. Buffers and oscillator divider. IC1 – 7492; ICA – 74S00; IC2 – 7400.

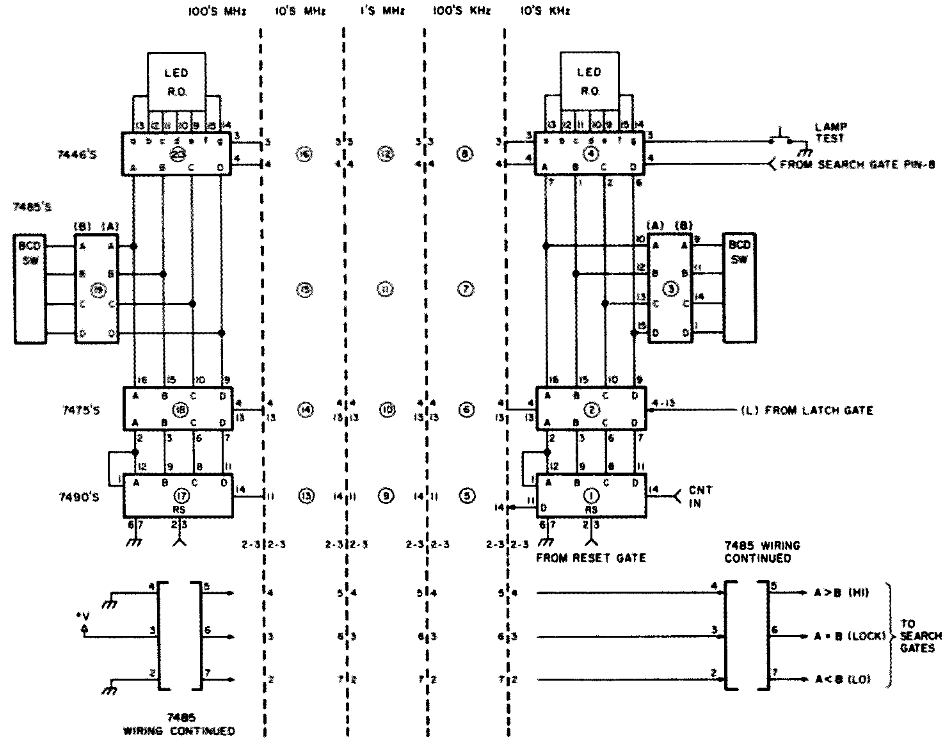

Fig. 4. Counter/comparator.

good enough, to remove the undesired harmonics of a square wave, but I did not want to chance that on a pulse type asymmetrical waveform you get from a divide by 2, then divide by 3. This is entirely unimportant for waveforms feeding more TTL, as only the high to low transition is important. The output 6 MHz signal goes through a buffer and gate for those who may find it necessary to shut off the oscillator output to the coaxial feedline to the transmitter (one feedline to more than one transmitter – choose frequency according to transmitter and transmitter by what PTT line is keyed).

The other direction the signal goes from the VCO buffer is to a divide by 25 in the form of a divide by 5, followed by another divide by 5. This is desired because the VCO runs at ¼ of the transmitter frequency, and dividing it by another 25 gives a total division by 100 and the same numbers as the output frequency only at 1/100 the frequency. This all allows a digital comparison to be made between this new 1/100 frequency and the BCD frequency select switches. Please note: The fact that this divided frequency and the switches match will show a "lock" condition and will run a transmitter by supplying it the proper oscillator frequency, but does *not* assure in any way that you are on frequency at the output any more than plugging in the right crystal does. All stages in the transmitter must still be properly tuned to proper multiplication frequency. The "lock" indication provides only the indication the VCO has moved to the correct new frequency and it is outputting to the transmitter. Gates are provided to allow no output while searching or out of lock and, of course, the provision of no output until keyed is included.

Bearing in mind that by keying oscillator output on and off, or to different transmitters, or holding it off during search, you will not be keying the oscillator VCO on and off, you can see that chirp and run-up is no problem. The oscillator is always running, and when it reaches proper frequency and the "lock" or transmitter ready indication shows, it merely means the oscillator output is gated on and frequency is being fed to the strip oscillator now converted to an amplifier. Some who read through the notes on this article shrieked at oscillator chirp and Class C stages running without drive in the transmitter, etc. For your, and their, piece of mind, this paragraph was added.

We are now down to the count and compare lines, and it is here the sneaky part enters. By feeding a 1.4 MHz region signal to what really is a frequency counter with a comparator added, a number that is 1/100 the output is counted. Since only the most significant 5 digits are important, that is all we count, by using a gate time of .01 second instead of 1 second. If a 1 second gate were used, the counter would overflow, too much time would be required to set up and keep comparing the VCO to keep it on frequency, and this scheme just plain becomes less feasible.

Let's take an example to show what goes on. 146.94 MHz is a common frequency, so let's follow it through. Since the VCO runs at the ¼ frequency, this means 146.94 MHz divided by 4 or 36.735 MHz. Divide this by 6 (to get the oscillator range frequency) and you have 6.1225 MHz. Multiply this by 24 in the transmitter and you have the 146.94 MHz output. Returning to the VCO frequency of 36.735 MHz and dividing by the fixed divide by 25 ICs, we have 1.469400 MHz to feed the counter. If you use a .01 second gate, then the counter will count and load .01 times 1.469400 MHz, or 14694 Hz. If the switches are set up for 14694, then, and only then, will the lock indication come on showing the delta dc module is not being turned on to charge or discharge, a fixed dc is being applied to the VCO, and a steady frequency is leaving the VCO that when divided by 6 is giving the right 6 MHz region oscillator signal. The nice part of all this versus frequency multipliers is that TTL division is quite fixed by the device when wired correctly. A divide by 6 is a divide by 6, etc.

You may have noted that the range of the VCO is all that limits how far you go on excursions with the VCO counter/comparator portion. Further, there is no need for fancy VHF PLLs, or dividers, or multiple PLL-mixers, etc. This alone made it worth trying for me. The very idea of an analog circuit where a digital one will work has a bad taste for me. I guess it is the fact it is so much easier to build, troubleshoot, maintain, etc., digital circuits, since everything is either on or off!

Now I mentioned earlier the idea was to run this whole thing as a digital master oscillator for all 3 bands (and later ideas of 1296 MHz FM!), but there came a few snags I am still working on. Let's take

6m first. The band of interest is 52.5 to 54 MHz and the Motorola strips require a 3 MHz region crystal and a times 16 multiplication. This band *can* be done as follows, and can even be added in as on mine, but bear in mind as with any versatile scheme, you will be capable of out of band operation, so be careful and pay attention to what you are setting up if you try it!

To get the same scheme to work on 6m, we let the same general region function for the VCO, but the VCO frequencies of interest are from 39.375 MHz to 40.5 MHz. These are then divided by 3 to get 13.125 to 13.5 MHz. These 13 MHz region frequencies are at ¼ of the transmitter output, the same as some frequency of the chain was for 2m. Therefore, dividing from this point gets you another 1/100 frequency if you use the same fixed divide by 25 pair used on 2m.

Again, let's use a common example, 52.525 MHz. Divide by 4 to get a VCO divided point of 13.131250 MHz, times 3 is a VCO of 39.393750 MHz. So, you divide the VCO by 3 to get the split point. In one direction you divide by 4 again to get the transmitter oscillator of 3.2828125 MHz. Toward the switch deck you do a fixed divide by 25 to get 525250 Hz. Since only one digit (the last) is insignificant here, we have to use a .1 second gate and settle for the slower lockup and less frequent comparison and updating of the VCO. Remember, this is still 5 updates a second, so you aren't going to drift very far with any VCO stability at all. The same switch deck is used to "dial in" the 52.525 MHz frequency as 052525. Since the gate is .1 second, it allows .1 times 525250 or 52525 Hz to pass into the counter, be compared, and match the dial in frequency.

Now the hard one! For 450 MHz, an 18 MHz region oscillator is required. This is easy enough by dividing our 36 MHz VCO by 2, so let's follow on through the range and a particular frequency. The range required (to cover it all) is from 420 MHz divided by 24 times 2 equals 35 MHz (not bad) to 450 MHz divided by 24 times 2 equals 37.5 MHz (again, okay). You do a divide by 2 to get the frequencies required by the transmitter from the VCO. Now to get a way to find the 1/100 frequency. To get down to the VCO frequency in the case of 2m, and to a lesser frequency in the case of 6m, only a division by 4 was required, allowing a further division by 25 for the 1/100 frequency for the switch deck. This gets tricky on the 450 MHz band, as any division that gets us to the VCO or less has an oddball divisor to get the 1/100 count. Further, suppose we run a divide by 10 approach to run the VCO from 42 to 45 MHz? Now an oddball divisor is required to get the 18 MHz required by the transmitter! We did not try to get any other crystal range, etc., for fear of not ending up right in the modulation department, but it is being looked into (i.e., a 6 MHz oscillator for all 3 bands, or even just 2m and 450 MHz).

This one will have to wait for now, unless you are willing to figure out the few places you run on 450 MHz and what those frequencies are when divided by 3 (or the 2m region equivalents). Example: If you take the 449.1 MHz simplex frequency, you get a 149.70 MHz "dial in." This is a VCO frequency of 37.425 MHz. This is well within the VCO range. A simple VCO to divide by 2 to a gate-buffer will supply the required oscillator frequency. A high band/UHF bandswitch would have to be added to control the destination and division from the VCO, and a small chart somewhere on the front panel to show the more commonly used UHF frequencies in 140 MHz equiva-

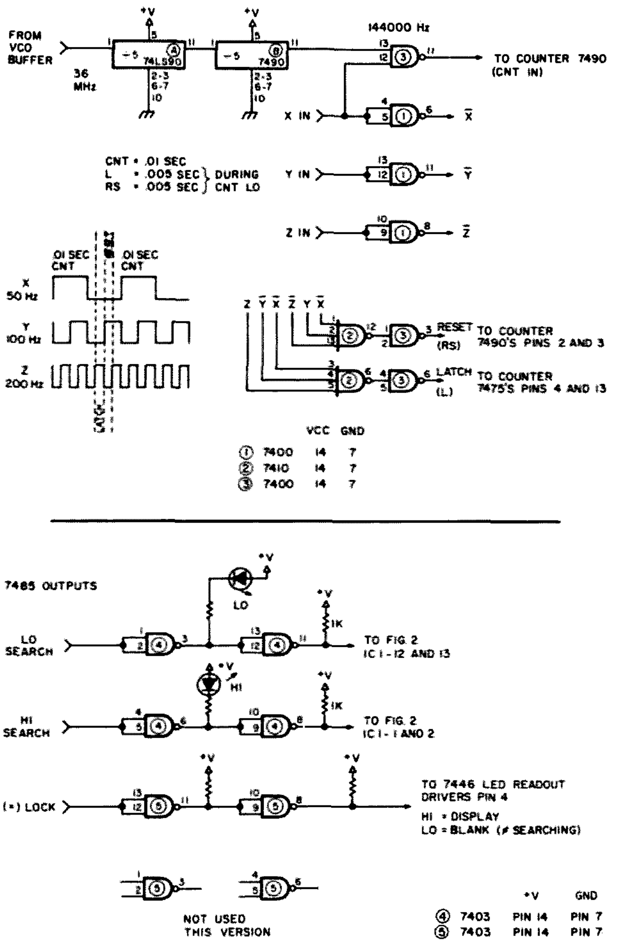

Fig. 5. Timing search.

lents. It would be wise to add in a panel lamp to show the band status anyway. The hundreds MHz A line can easily be used for this on the 6m band, as the low on the A line can be inverted and used to enable the 6m oscillator-gate-buffer, and the A line high can run the equivalent gate directly on 2m. You can even use the C line (4) if the switch scheme can be figured out for the 450 MHz use.

I believe this describes the how to, and a wire by wire shouldn't be required. Enough counter articles have come out to explain the 7490-7475 counter part, the 7490 timebase (we run one master for a lot of things in the station – clock, etc. – to save duplication and money), and the time gating arrangement. Only the 2m version is shown to avoid confusion, but as the 450 MHz version is worked out or as interest demands, maybe a future article will include the other 2 bands – I have left provisions!

SASE for help. The "Junque" BC-348 articles will resume. Happy TTL, and I hope you are learning as you build. It can be a lot of fun, and if you don't think the electronic industry doesn't think digital is the way to go – look again! ■

Note: **The modifications required to change over the oscillator tube in the FM strip will vary with the model, type, and whether Motorola or GE, etc. All that was required on mine is as follows:**

1. Remove C105 (150 pF)

2. Replace C101 (50 pF) with .02

3. Remove C102 (10 pF)

4. Install 220 Ohm resistor in parallel with R103 (47k)

5. Install BNC or like connector near crystal socket on new F2 deck, and wire center pin to grid of 6AK6 added as second (F2) oscillator (now an amp).

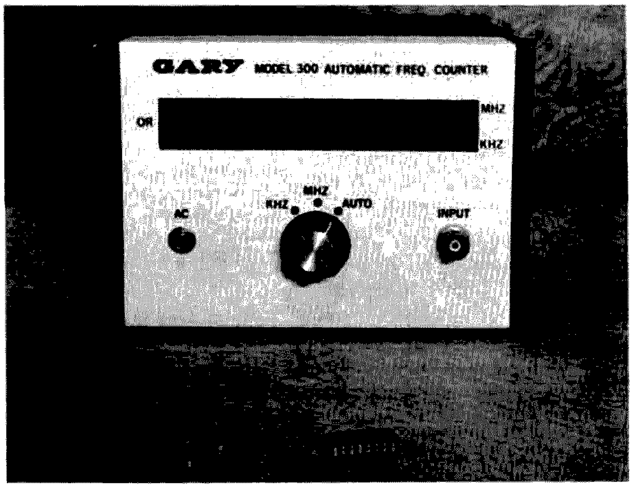
Selecting A Frequency Counter

-- pitfalls to avoid

Thanks to microcircuits, there has been a major revolution in test equipment within the last few years. The prices of devices such as digital voltmeters, triggered sweep oscilloscopes, and others have dropped dramatically, a neat trick considering inflation! But more important, this excellent, low cost gear is getting into the hands of servicers and electronics enthusiasts where good equipment is both useful and necessary to cope with today's advanced products. The frequency counter has also benefitted from microcircuits and price cuts, but only recently has it begun to "take off" with electronic hobbyists and service people. I think that this may be due to the past high prices, and a misunderstanding of what a frequency counter can do. But these things are going to change as more people are discovering what a counter can do for them!

I am going to show you some of the things to look for when you shop for a counter, and some of the not-too-obvious pitfalls to avoid. There's a lot more than specs to consider, too — all counters have special features that may be obvious or not in the advertising literature. In short, I am going to try to make your selection a better one by showing the more important *general* features and explaining them, so you'll know what to look for. As for myself, I work for a company that makes counters, and I have to use them nearly every day. So I am in a very good position to help you!



Some of you skeptics are probably thinking, "Why do I need a counter?" A good question, indeed. Have you ever designed/built an oscillator and couldn't find the frequency? Then spent hours pruning the circuit to the proper frequency? A counter would tell you where you are at a glance. Or have you ever aligned a filter or trap or i-f stage and found that the center frequency was a city block off? A counter would help you keep tabs on the calibration of your signal generator and get a better alignment in the bargain! Have you ever had trouble accessing the local 2 meter repeater? A counter can tune up that tone generator in a jiffy. Ditto the transmitter with a VHF counter. Or, perhaps you are a CBer and people complain that you "bleed" on several channels. This could be caused by a sick transmitter with a bad crystal(s). A qualified technician can easily check this out with a good counter. Anybody still skeptical? Remember that you can do far more with a counter if you put your imagination to work!

A Wee Bit of History

You might be interested in how frequency counters evolved. The first method of frequency measurement evolved around the turn of the century when it was necessary to measure the frequency of radio transmitters. The gadget was called a *wavemeter* and it consisted of a paralleled coil, variable capacitor, and spark gap (later replaced with a meter or light bulb). The capacitor had a calibrated dial, and it was adjusted until a spark appeared at the gap. The frequency was either read off the dial or extrapolated from a coil/capacitor chart if the dial read pFs. By the '30s, another form of frequency measurement came into vogue: the *frequency meter*. This unit had a built-in frequency standard and the unknown was mixed with it; the meter was adjusted until the signals "zero beated" in the headphones that were part of the unit. Old-timers will no doubt recall the

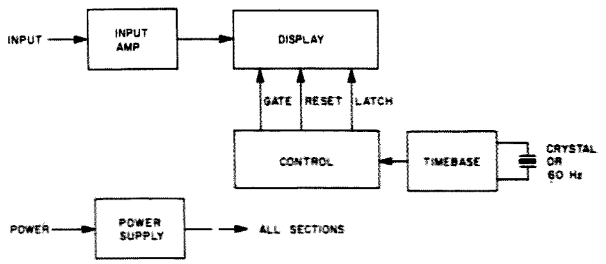


Fig. 1. Block diagram of a basic counter. The circuitry of modern counters is in ICs — mostly 20 to 30 packages of TTL.

BC-221 and LM frequency meters of WW II vintage with this mention — they were very famous! Digital electronics was the next development, and a digital frequency counter appeared in the early '50s. The first ones had 40-plus tubes, had neon lamps arranged in 0-9 columns for a readout, and were called EPUTs (Events Per Unit Time meters). The top frequency of those early counters was only a few MHz at most, although VHF range extenders appeared quickly. The early manufacturers were Berkley Scientific and Hewlett-Packard. The next step was in the '60s when ICs became available. Counters became smaller and much cheaper, too. Many companies are still using these warmed-over circuit designs today, despite advances such as CMOS. Recently, one semiconductor company has introduced a "2 chip" counter, where all of the major parts of a 6 digit counter are on 2 LSI chips! Needless to say, the future has much to hold!

A Look at Basic Specs

You have probably looked over enough of the ads by now to realize that selecting the right counter takes some thought and an understanding of counter fundamentals. Without these things, you could end up with a 3 digit "toy" and have to align a generator that is 10 times more accurate, or a unit that is so versatile it does everything but makes the morning coffee (extra cost option), to check a phono oscillator. So, needless to say, the way to start is to sit down and analyze *your own needs.* Ask yourself such questions as, "What am I going to use a counter for?" and "What do I expect to be doing with my counter within a few years?" These questions will help you decide the *primary* features that you must have in the counter you select.

For example, suppose you are an experimenter and you like to work with audio circuits and TTL logic. This suggests that you should start looking for a counter with a 20 MHz maximum range, because that is probably the highest frequency you are working with (frequency limit of standard TTL). Accuracy probably isn't critical to you and you might be able to settle for a unit that is 0.03% accurate.

Or perhaps you are a professional servicer and you are getting into CB repair. Your requirements are more strict. Since CB is 27.255 MHz maximum, you need one of the popular 30 MHz counters. Also, you need a counter that is 0.001% or "10 parts per million" (abbreviated 10 ppm) accurate to satisfy FCC requirements.

Consider the future, too. If the experimenter upgrades to, say, CB, he'll need a faster counter. But there are devices such as *prescalers* to extend the range of counters at low cost. So, when the day arrives, he might only have to add a low cost black box to his counter.

On the other hand, if the servicer upgrades to commercial radio repair, he may have to replace the counter. Why? The frequency tolerance of commercial gear is often 0.0005% and that requires a counter of 0.00001% or 1 ppm. That spec is 10 times better than the old unit's! These are a few thoughts to keep in mind when you start your search for the right counter. Try to anticipate the future!

Let's list the primary specs of a frequency counter and then discuss them. *Note:* They are not necessarily listed in order of importance.

1. Accuracy
2. Input sensitivity
3. Minimum and maximum frequency range
4. Display
5. Power supply
6. Special features or options

Accuracy

The accuracy of a frequency counter is determined by a quartz crystal or sometimes the ac power line (60 Hz). Fig. 1 shows a block diagram of a simple frequency counter. As you can see, the crystal/60 Hz is divided in frequency to operate the rest of the counter; this entire section is called the *timebase.* The timebase (or TB, for short) is the heart of the counter and its accuracy determines the accuracy of the counter. Price is also a function of the quality of this section. You'll find counters that use the 60 Hz line as a frequency element that sell for up to $150, and you'll see units that have crystals in *ovens* (temperature stable enclosures) that sell for $6000 or more. The difference in accuracy is incredible: The 60 Hz TB counter will average 0.034% accuracy, the average accuracy of the 60 Hz coming out of the wall, to 0.0001% and better for the crystal oven unit! This is clearly one area where money talks. Typical counters run 0.005%

Inside a Modern Counter

The frequency counter is still undergoing some changes, as this photo of the Gary Model 302 Pocket Counter shows. You are looking at a 20 MHz, 4 digit unit that can be expanded to show up to 6 digits of readout. Power consumption is under 0.63 Watt, as compared to the 5 to 7 Watts required by a comparable TTL unit. The secret of this unit is hybrid construction of CMOS and TTL logic. The heart of this unit consists of 3 CMOS/LSI chips. The DCU section which many hobbyists would build with 12 or more chips is contained in one special CMOS IC. The timebase section has two more CMOS ICs, replacing at least 6 TTL chips. The front end or Schmitt trigger deserves special attention because the input amplifier is the hardest part to design in a counter. This one has an FET amplifier and a biased NAND gate that serves as a Schmitt trigger. Sensitivity is excellent — 50 mV at 20 MHz with this arrangement. As you can see, counters have changed quite a bit, and they will continue to do so as more people continue to show so much interest in them.

(50 ppm) to 0.001% (10 ppm). They use 4 MHz or 10 MHz crystals without ovens for low cost. These crystals are usually custom ground and the TB is carefully adjusted to get this degree of accuracy.

When you shop for a counter, try to get a counter with as much accuracy as you can to suit your needs. Remember you need at least a 10 ppm timebase for CB repair work, if that is your interest. The 60 Hz units are not for serious electronics work; 0.034% accuracy is terrible in the counter world. Anyhow, the few units available with these may be off the market by the time you read this!

Input Sensitivity

Another sign of a counter's quality is the sensitivity it has to measure the frequency under question. Fig. 1 shows an *input amplifier*, the section that has to do with the input sensitivity, and Fig. 2 shows a block diagram. The job of the input amplifier is simple: It amplifies the input signal and converts the signal to a corresponding set of pulses that is necessary to drive the counter's digital circuitry. The heart of the unit is the *Schmitt trigger*; it converts the incoming signal, which may be any kind of a waveform, into the necessary digital square wave. Generally, when you read input sensitivity specs, you must assume that the sensitivity refers to the minimum signal required at the maximum rated frequencies of the counter to get a steady reading. In other words, the specs are worst case. Generally, the sensitivity of most counters is not flat over frequency, hence the min-signal-at-max-frequency bit. Fig. 3 shows the sensitivity plot of the Gary Model 301 Counter, a 32 MHz unit. As you can see, the input sensitivity is not flat! But in this case, a non-flat sensitivity curve can work to your advantage: The high gain at audio frequencies allows use of devices such as microphones and magnetic pickups for organ tune-ups and tachometers. The lower gain at 32 MHz reduces the chance of overload by radio transmitters, too.

Typical input sensitivity is on the order of 10 mV to 120 mV for most counters. It is desirable to get a counter with slightly more than enough sensitivity to do the job; in most labs, 100 mV worst-case does fine.

You will also find a maximum input voltage spec on some units. This refers to the maximum voltage you can apply to the counter without damage. This is always the *peak* ac signal plus any dc that may be present in the signal. For example, suppose you are measuring the signal of a homemade oscillator directly at the collector of the output transistor. You have, say, 9 volts dc at this point, plus, say, a 6 V peak-to-peak signal: You are applying 9 V dc + 3 V peak or 12 volt worst case to your counter! Fig. 4. illustrates this. This spec isn't really important to you unless you work around high voltage tube circuits and moderate to high power transmitters. In this case, there are counters built with range switches (usually calibrated x1, x10, x100, etc.) for use around high voltages. Typical maximum voltages are 20 to 100 volts for counters without range switches and 500 volts for the ones with them. These voltages are rated at a counter's maximum rated frequency, where the maximum input voltage must be reduced to prevent damage to the input amplifier. At low frequencies, such as 60 Hz, most counters will handle 120 V ac without problem.

Min/Max Frequency Range

This is probably the most advertised feature of frequency counters. Everywhere you look you are bombarded with ads screaming, "30 MHz Counter," "80 MHz Counter," "Or How About A 250 MHz Counter . . ." and so on. Yet top frequency isn't all that important. A 30 MHz counter measures a 27 MHz signal as readily as an 80 MHz unit or even a 250 MHz unit or above. Yet, the price difference between these models can be at least several hundred dollars. All you are getting for the extra money of a faster counter is a unit with more capability. And that's fine if you sometimes need a counter to measure VHF signals; otherwise you can save money if you stick to a lower cost, lower frequency counter that will read the maximum frequency you expect to be working with. Remember, too, that low cost prescalers are available that divide the input signal by 10, so you can have your cake and eat it too! (Gary McClellan and Company now offers two counters with built-in prescalers. – Ed.)

An often ignored spec is the minimum frequency a counter will display. This depends upon the timebase and the sensitivity of the input amplifier. In order to get any accuracy from a counter when measuring slow signals, at least 10 Hz must be displayed on the standard MHz range switch set to *kHz* (actually 1 second gate time). Why? All counters have a built-in ± 1 count inaccuracy due to the circuitry. That's 10% of 10 Hz – in other words, your 10 Hz is 10% accurate! Also, TB errors show up in these digits, and can worsen or even improve accuracy at this point. The input amplifier sensitivity may drop at this point, too, making it hard to pick up low frequency signals. It's safe to say that the low frequency limit of most counters is 50 Hz for good accuracy (5x the minimum frequency is good test equipment practice) even though the counter will read lower frequencies. If you do a great deal of measuring at low frequencies, you should consider a counter with a 10 second gate time, or a unit with a frequency multiplier, notably the Heath IB-1103. They will give you a display such as 60.1 Hz (10 sec TB) or 60.030 Hz (IB-1103).

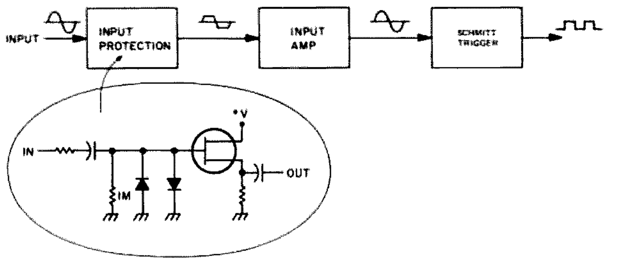

Fig. 2. Expanded drawing of input amplifier and a rough schematic of a typical input circuit.

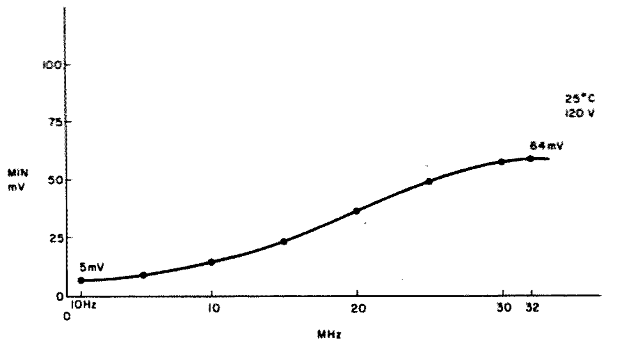

Fig. 3. Input sensitivity of a commercial counter. This plot shows the minimum voltage required to get a stable reading on the counter.

Display

The display on a counter can have a powerful bearing on whether you buy a certain model or pass it up. Important things here are the appearance of the digits and the number of them. LED type displays currently reign supreme in counters, so this is mostly what you'll see. Nixie tubes are seen in some older ac-only counters, but their use is dying out. Liquid crystals show promise for the future, because they don't require the high current of LEDs and the high voltage of Nixies. When you shop, look for the largest and brightest display you can get, but do not let the appearance of the display bias your thinking: Accuracy and sensitivity are far more important in determining your choice.

The number of digits should be considered, also. As a rule of thumb, five to six digits are about the optimum number. Fewer (such as the three digits found on an inexpensive kit) require complicated range switching or more knob turning for you. And more digits can be confusing to read. Ever see 146.96 MHz read out on a large counter as 146960001 Hz? It's very confusing at times. Also, large digit counters consume larger amounts of power; consider that if you are buying an ac/battery model!

Power Supply

Some counters offer you different ways to power themselves, often at no extra cost. The most common power source is 120 volts, 60 Hz. You'll find many units that can be wired for 240 volts ac, but you may have to check the operator's manual to find this out. There are also counters that have 120 V plus 12 V dc connections. You can often plug them into a cigarette lighter for working on mobile electronics. A few battery operated counters are becoming available, but at present none have the full features of the other models.

Special Features/Options

A whole plethora of special features are available on counters. Switching ranges from a simple kHz/MHz switch to a full blown range switch of 0.01 ms to 10 sec. Inputs range from simple jacks to complicated attenuators and trigger level controls. Input impedances may be different, too. You'll find the standard 1 meg plus 10 to 50 pF input and a straight 50 Ohm input (for VHF) on some units. Some of the more expensive units have timers/stopwatches and time interval measuring features built in. And the list could go on. Base your selection on what features you really need and not what looks nice. It makes no sense to buy a \$300 counter/timer, then use the timer once and spend the rest of the time measuring frequency!

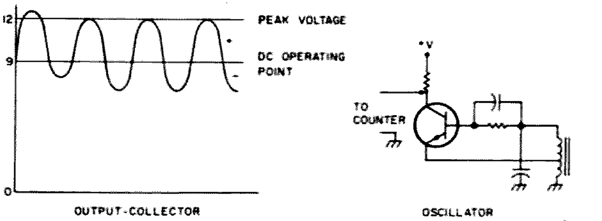

Fig. 4. Calculation of peak or worst case voltage that could appear across a counter input. Note sample circuit.

Most options can be quite useful. Some popular options include frequency range extenders, high stability TBs, power cords, etc. Also, don't overlook good probes and cables. A x10 scope probe is often used with the standard 1 meg input counter and will increase the maximum input voltage 10 times, preventing overload in most cases, and making connection to the equipment under test much easier. Needless to say, this is a very handy option and one that you should consider! If you feel that you must go for options, try to anticipate future needs. Sending a counter back to the manufacturer for modifications at a future date is usually much more expensive than ordering everything at the same time.

Some Pitfalls

Let's wrap this discussion of counters up by briefly mentioning some pitfalls that can trap you. In the past sections, I have mentioned problem areas and pointed out ways to avoid them. But here are some of the other areas to watch. Accuracy specs are sometimes hard to find on a counter data sheet, and when you do find them, they may not be complete! Although the data sheet may say "Accuracy: 10 ppm," nothing is said about the temperature or supply voltage, all of which affect the accuracy slightly. If accuracy is important to you and you are in this situation, it may pay to contact the manufacturer. Input amplifiers also have questionable areas. The input circuit of counters without attenuators should have an overvoltage protection network, usually diodes. Check. If the counter doesn't have one, avoid it or you'll be doing a lot of repair work on the counter! Finish up your evaluation by looking over the counter for any other features that you think will cause trouble.

If possible, try to get a "hands on" demonstration of the unit you select. Make sure that everything works to your satisfaction, and that the counter lives up to your expectations. With the information I have given you, the selection should be easier, as you should be aware of the *basic* things to look for in a counter. Good hunting! ■

Build A Multiplying Prescaler

-- adds value to any counter

For several years I've been fascinated by tone signalling like subaudible squelch, touchtone,* tone burst and sequential tone paging systems. If I had been rich or lazy, I probably would have bought commercial modules for my experimentation, but since I am neither, I've been trying to build my own. One large advantage in buying any electronic device is that one needs a minimum of test equipment to get it working. However, if you "roll your own," the more sophisticated the performance you want, the more sophisticated your test equipment must be. Like most home experimenters, I have an oscilloscope and VOM and have managed to acquire an audio oscillator, power supply and ac millivoltmeter at relatively low cost at local hamfests. The one piece of gear I've been badly lacking is a frequency counter. Fortunately, there have been numerous construction articles for them in the last ten years in the ham and hobbyist magazines. The one I built is similar to the K2OAW counter.[1,2,3] This is entirely adequate for most uses an amateur has, but I wanted better performance at audio frequencies. This article describes the frequency scaler I came up with and details the design process I went through in achieving the final circuit. If you are interested only in the final product, please feel free to skim the article for details. But if you'd like to "look over my shoulder" to watch the design evolution, perhaps you can benefit from my experiences in your own ham projects.

Project Goals

What I wanted was a circuit to use with a counter to enable me to measure audio frequencies of 20 Hz or higher to within 0.1 Hz or so. For example, a widely used subaudible squelch tone is 114.8 Hz. I wanted to be able to measure this frequency and know that it was 114.8 Hz and not 114.7 or 114.9. The basic unmodified K2OAW counter will not do this. Its maximum resolution is 1 Hz. This is so because in the Hz mode it counts the number of cycles that occur in one second (see Fig. 1). Therefore, it would read 114 or 115 Hz because only that many cycles occurred. Being digital in nature, it cannot resolve fractions of cycles. (Because of the rounding off error of the gate there is a ± 1 count uncertainty. Unless otherwise specified, this will

*AT&T trademark.

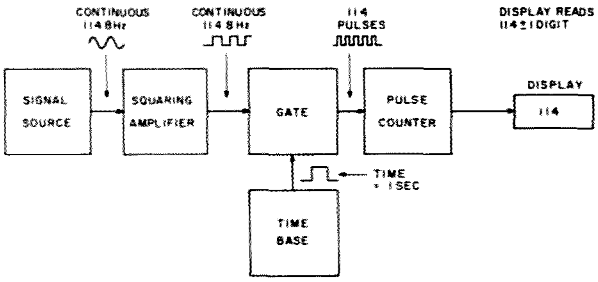

Fig. 1. K2OAW counter in Hz mode. Gate opens for 1 second, allowing 114 pulses to be registered in pulse counter and displayed.

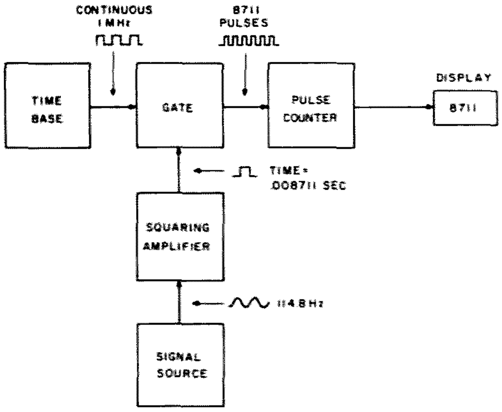

Fig. 2. High resolution can be obtained by measuring the input signal's period rather than its frequency.

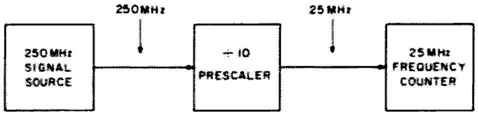

Fig. 3. Using a (dividing) prescaler to extend the high frequency capability of a simple counter.

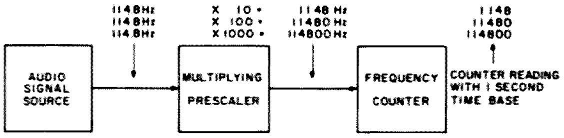

Fig. 4. Using a multiplying prescaler to improve measurement resolution at low frequencies.

be assumed for the rest of this article.)

The simplest method of gaining added resolution is to allow the gate of the counter to remain open longer so that it will pass more pulses. To get 0.1 Hz resolution means that the gate would have to allow 1148 pulses to go through; thus the gate time would be 10 seconds rather than 1 second. This approach works and has been used in frequency counters for years. But 10 seconds is a long time to wait for a reading. In fact, in the K2OAW counter, the update would take 20 seconds because of the nature of the gate circuitry. When you're setting an oscillator or filter on frequency, a 20 second wait between adjustments seems like an eternity. Needless to say, this simple method was not what I wanted.

Another way of quickly getting good resolution is to sort of turn the counter around. Instead of allowing the timebase to open the gate and pass the incoming signal to the counter section to be counted, it is possible to open the gate in response to the incoming signal and then pass pulses from the timebase to the counter section. Fig. 2 shows this setup. Here the input to the gate is a 1 MHz square wave from the counter's timebase. The input signal opens the gate, allowing the 1 MHz signal to pass to the counter section. At 114.8 Hz, the gate opens for 1/114.8 = 0.008711 seconds, allowing 8711 pulses from the timebase to be counted and displayed. This setup measures the *period* of the signal source in microseconds. To get frequency, you have to take the reciprocal of the period. So, 1/.008711 = 114.79738, according to my pocket calculator. Rounding off to the nearest tenth of a Hertz, we get 114.8 Hz. The period method, as presented, gives the required resolution, and gives fast reading updates, but it doesn't give a readout directly in frequency. Numerous commercially available frequency counters measure period. It can be handy to measure time, but it's awkward for frequency measurements.

Some frequency counters, like the Heathkit SM109 and the HP 5360 get around this problem by adding a "brain" to the basic counter. They are called "computing counters" and include logic circuits between their counter and display sections. The logic circuits take the reciprocal of the period and display a frequency readout directly. Anyone so inclined could interface a microprocessor or cheap calculator chip to perform the inversion. One brave soul has done just that.[4] His combined frequency counter, calculator, etc., is an elegant way to build a computing counter. But I already had a frequency counter and didn't need a little computer, too.

The scheme I finally decided on is analogous to the method used to extend the high frequency range of an inexpensive frequency counter. This scheme is known as prescaling. K2OAW used the prescaling technique to enable his 25 MHz counter to read up to 250 MHz. The method is shown in block diagram form in Fig. 3. The frequency counter won't operate by itself much above 25 MHz, because the ICs used operate too slowly. The prescaler, however, uses a special divider IC which will operate up to 250 MHz and produce an output at 1/10 of the input frequency. Thus, for 250 MHz input, the output is at 25 MHz, which the basic counter can handle. The price paid for this frequency range extension is in measurement resolution. If the input to the prescaler is 200,000,001 Hz, its output would be 20,000,000.1 Hz. With one Hertz gating, the 1/10 Hz digit would be lost, so the best resolution of this counting method would be 10 Hz at 200 MHz.

What does this loss of resolution at VHF have to do with added resolution at 20 Hz? That's simple. To gain low frequency resolution, we use a prescaler that multiplies the input frequency instead of dividing it. Fig. 4 illustrates the use of a multiplying prescaler. If the prescaler multiplies the input frequency by 10, the last digit of the output frequency corresponds to 1/10 Hz of the input frequency. Similarly, a x100 multiplier has an output corresponding to 1/100 Hz in the last digit. If the frequency counter uses a one second gate, then, a x10 multiplier gives 1/10 Hz resolution, x100 gives 1/100 Hz, and x1000 allows you to see 1/1000 Hz as the last digit of the input frequency. No sacrifice in counting speed is incurred, and the only arithmetic involved is remembering where the decimal point has to be placed in the counter's display. I wish I had thought of this method first so that I could patent it, but I'm years behind the test equipment industry. Systron-Donner and others for several years have manufactured frequency counters that use the same principle.

Now then, how do we multiply the input frequency by the right factor? Well, one way involves the use of a phase locked loop (PLL). Fig. 5 shows the block diagram of such a multiplying loop. The input signal is compared in phase with a signal from the divider shown, to produce an error output voltage. This voltage, in turn, is filtered and applied to a voltage-controlled oscillator (VCO). This voltage tends to retune the oscillator so that the output of the phase comparator is minimized. The net effect is to keep the frequencies of the two phase comparator inputs identical, but with a slight phase difference. The output of the VCO, however, is at 10 (or 100 or 1000) times the input frequency, and its frequency is locked to the input frequency. Thus, if the input is 114.8 Hz and a ÷10 divider is used, the VCO output is 1148 Hz, which is exactly the desired result. The above is an exceedingly oversimplified description of PLL operation, but it should

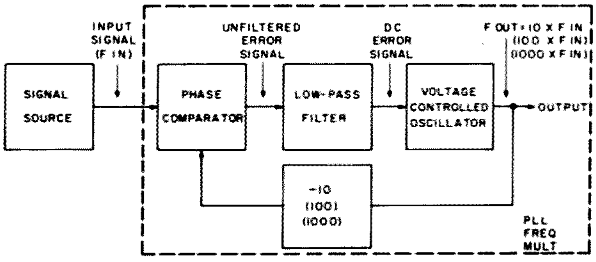

Fig. 5. Phase locked loop frequency multiplier.

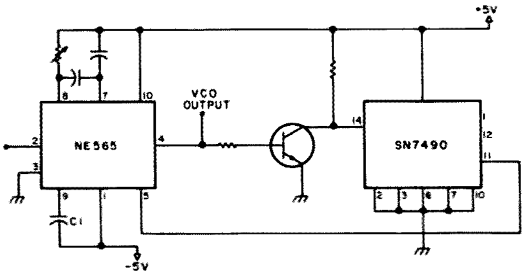
Fig. 6(a). First circuit attempt of PLL frequency multiplier.



be adequate to demonstrate the multiplication principle. By the way, digital frequency synthesizers use the same basic principles with variable dividers to lock VHF signals onto lower frequency crystal oscillators.

Well, so much for the design concept. The thinking outlined above took lots of spare time over a six month period. After all that mental effort, I wanted to heat up my soldering iron and build something! The first attempt is shown in Fig. 6(a). The circuit was "borrowed" from a Signetics data sheet for the NE565 PLL chip. Component values have been intentionally omitted so that you won't be tempted to build it. Theoretical operation is the same as for Fig. 5. The input signal is applied to one input of the phase comparator via pin 2 of the NE565. The VCO in the 565 runs at 10 times the input signal frequency. The VCO output is divided by 10 by the 7490 and applied to the second phase comparator input via pin 5. The phase comparator output *should* try to lock the VCO at ten times the input frequency. It didn't. I tried different devices, readjusted component values, varied supply voltages, rewired the circuit several times, and nearly fried the 565 with too much input signal. But the #@*!! thing would not lock! At least it wouldn't lock at 10 x F_{in}. It liked 20x and 30x instead.

I had noticed, though, that it would lock at the input frequency if the divider was removed and pin 4 of the 565 was jumpered to pin 5. Similarly, locking was possible at F_{in} x2 with a ÷2 divider, F_{in} x4 with a ÷4 divider and F_{in} x8 with a ÷8 divider. This was a clue that something was wrong with the ÷10 section. The output waveform was perfect except for one thing: It wasn't symmetrical. It had a 20% duty cycle, since the output pin was high during only the last two input cycles out of ten. Very quickly I set up the 7490 for a symmetrical output as shown in Fig. 6(b). Finally, I could get the VCO to lock at ten times the input frequency. Further reading on phase comparators revealed that the doubly-balanced multiplier used in the NE565 likes to see signals with a 50% duty cycle. If it strays far from 50%, screwy things happen just like I had noticed.

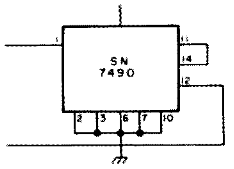
Now that I had a working breadboard circuit, I wanted to see how well it would work. I tried to get it to multiply various frequencies in the audio range. One serious drawback very quickly appeared, though. The capture range was too small. That is, the circuit wouldn't lock onto a signal very far from its free-running frequency. For example, if it free-ran at 600 Hz, it would only lock from 450 Hz to 750 Hz or so. That meant that the multiplier would have to be coarsely tuned to the operating frequency each time it was used. Also, I was restricted to a 10:1 tuning range. The manufacturer recommends that R1 be between 2k and 20k Ohms. To cover the audio spectrum from 20 Hz to 20 kHz would require switching in 3 different values of C1 in addition to a "diddle" pot for fine tuning. This seemed awfully awkward. What I really wanted was a minimum of controls.

Just about the time I reached the impasse, though, I had a need to use some phase locked loop techniques at work. I had all sorts of practical knowledge from my lunchtime and evening work with the multiplier, so I dug out the textbooks, application notes and IC data books for some theory. After too much math and sore eyes from reading, I found that using a PLL with a doubly-balanced modulator phase detector wouldn't do the job. It's fine for relatively narrowband PLLs and works well with noisy signals, but had too many drawbacks to be practical for my multiplier. Something like the Motorola MC4044 seemed much more practical.

The 4044 is really a phase frequency detector. It consists of interconnected logic gates and flip-flops which give it an interesting characteristic. For signals close in phase on its inputs, it gives an output proportional to the phase difference between the two signals. But if the signals are not close in phase, it outputs a steady dc level. The second characteristic makes the 4044-type phase comparator far different from the doubly-balanced mixer. The 4044, in contrast to the 565-type comparator, is very useful for a wideband phase locked loop. Incidentally, it's also useful for narrowband PLLs, too. Many commercial frequency synthesizers use this IC.

The 4044, though, was of no use to me in my project at work. It simply consumed too much power. The system that I wanted to put the PLL in used all CMOS (Complementary Metal Oxide Semiconductor) integrated circuits, running at less than 5 V and consuming microamps of

Fig. 6(b). Correct connections for symmetrical ÷10.



current. The 4044 needs 5 volts at 40 mA! Further research of the data books revealed the RCA CD4046. This was just the IC I needed, both for my work and home projects.

The 4046 is a CMOS IC which contains two phase comparators and a VCO. See Fig. 7. Phase comparator I is an exclusive OR gate which behaves like the doubly-balanced mixer phase detector. Phase comparator II, however, is what RCA calls an "edge-controlled digital memory network." Forget the long name. It's basically the same phase frequency comparator that the MC4044 uses. Phase comparator II is intended for use in wideband PLLs. The 4046 is almost like the NE-565 in low power form. And it's more versatile.

Now that I had a practical and theoretical background in PLLs, it took only a few hours to come up with the bare bones of the working multiplier as shown in Fig. 8. For a first attempt, I set the VCO just below 60 Hz and connected the VCO output (pin 4) directly to the phase detector (pin 3). Sure enough, when I applied a 60 Hz signal to pin 14 (the input), the VCO locked on and read exactly 60 Hz. Excitedly, I connected a CD4017 to divide by 10 and hooked it between pins 3 and 4 of the CD4046. Next, I replaced C1 with a new capacitor one tenth its original value. With no input signal, the VCO now read about 500 Hz. When the 60 Hz source was reconnected, the VCO read precisely 600 Hz! At long last, the multiplier was a reality.

Next, I calculated resistor and capacitor values per the RCA CMOS data book to

tune the VCO over the range of 20 kHz to 200 kHz. For these values, the multiplier is useful over the usual audio range of 20 Hz to 20 kHz. For 20 Hz to 200 Hz, the VCO runs at 1000 times F_{in} and the required divider (Fig. 5) is a ÷1000. For 200 Hz to 2 kHz, the multiplication is 100 with a divider of 100. Finally, the 2 kHz to 20 kHz range is multiplied 10 times using a ÷10 between the VCO and phase comparator. Keeping the VCO tuning range constant and changing dividers is the most practical method of using the multiplier over the audio range. Little is sacrificed in having a smaller multiplication factor for the higher audio frequencies, though, since my method provides a constant resolution percentagewise over the whole range.

The original breadboard was wired up on an AP Superstrip.TM These strips are rather expensive (about $18), but are extremely useful for anyone who likes to experiment because you can try out a new circuit almost as fast as you can draw its schematic. Since the circuit was easy to change, I tried all three multiplication ratios just to be sure. This only meant changing a few wires, and I wanted to be sure that all was working on the breadboard. I wanted no surprises in the final version.

Now that the breadboarding was successful, I decided to build the circuit in final form and put it in a cabinet. I didn't want to bother with a PC board, since I was building only one, so I used the wire-wrapping technique. I used wire-wrap IC sockets (10¢ each at a hamfest) and 0.1 inch vectorboard. Wire-wrapping was accomplished with a $2.50 tool made by Cambion (their part number 45-1816-01-00-16). This tool, incidentally, is widely available at electronics parts houses. It's great for small wrapping jobs and costs less than $3.00, as opposed to $50 or more for motorized wrappers. At the same time that I hooked up the multiplier, I added an input amplifier which will be described later.

When I fired up the wrapped wire version, all sorts of strange things happened. First, the VCO kept locking up at the high end of its range without any input signal. This shouldn't be, because the phase comparator should have zero output with no input. And when I applied an input signal, the loop would try to lock, and then wander all over the place in seemingly random fashion. I was really perplexed because the breadboard had worked so well. My scope showed that there were pulses at the phase comparator output even with the input of the linear amplifier grounded! But when the input to the PLL IC was grounded, the pulses disappeared. Obviously, there was junk coming out of the linear amplifier, but I couldn't see it on my oscilloscope. I took the circuit into work the next day, to have a look at it with a decent scope. Sure enough, there were very narrow spikes being fed to the PLL IC even when the linear amplifier's input was bypassed to ground. I found that if the PLL IC was disconnected (pulled from its socket), the pulses went away. Now the light came on. The VCO signals from the PLL IC were being coupled to the linear amplifier by stray wiring capacitance. With the Superstrip, this coupling didn't occur, but wire-wrapping gives much more possibility of this stray coupling to exist. The linear amplifier was constructed from CMOS, so its high impedance inputs were very susceptible to capacitive coupling.

CMOS is extremely *insensitive* to noise when used in digital circuits, because the outputs are full "on" transistors at either ground or Vcc. However, the output impedances are much higher when

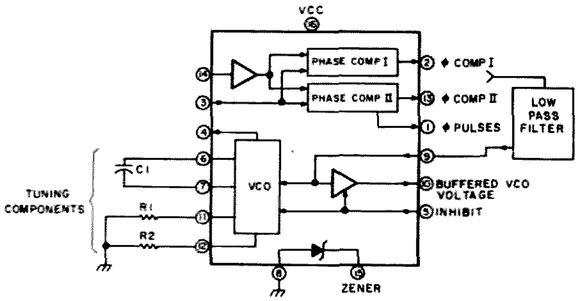


Fig. 7. RCA CD4046 phase locked loop IC.

the devices are biased in between to work as linear amplifiers.

To eliminate the problem of coupling, I built the input amplifier using point-to-point wiring on a piece of perfboard, leaving the PLL IC and dividers connected in wrapped wire fashion. The circuit behaved much better, although there was still a trace of VCO instability. This was cured by connecting the VCO tuning components R1, R2, and Cl to the IC with short-direct point-to-point wiring, and dressing the pulse-carrying wires away from these components. Apparently there had been the same strays noted earlier being induced into the VCO. Finally, everything worked well using point-to-point wiring for the linear amplifier and PLL IC, and wire-wrapping for the digital dividers.

When I got tired of the boards lying loose on the bench with wires dangling all over the place, I put it in a cabinet, a 2 x 4 x 6 shadow-box from Lafayette. Since then, two additional models have been built, and a half dozen or so sets of ICs substituted. All of them worked okay, except that one of the PLL ICs required a slight readjustment of the VCO range pot.

The Final Circuit

Several minor revisions occurred in the process of building the three packaged versions mentioned. Fig. 9 is the schematic diagram now that the design is "frozen."

The input circuit is detailed in Fig. 9(a). IC1 is a CD4001AE CMOS integrated circuit designed for logic circuits. In this application, it is an ideal amplifier and squaring circuit. The first gate, the "A" section, is biased as a linear amplifier by the 1.5 megohm feedback resistor. Input signals to it are ac coupled by two capacitors, and a sensitive control potentiometer sets the input level. The 47 pF feedback capacitor rolls off the amplifier's high frequency response to lessen sensitivity to stray pickup and high frequency transients. Gates B, C and D shape the input signal from a sine wave into a steep-sided square wave of about 5 volts p-p.

The phase locked loop section is shown in Fig. 9(b). IC2, the CD4046, is the actual PLL, while IC3, 4 and 5 are digital dividers. R1, R2 and C1 are the VCO tuning components. R1 sets the high

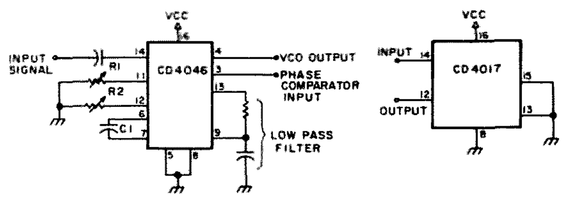

Fig. 8. Breadboard circuit for the successful PLL frequency multiplier.

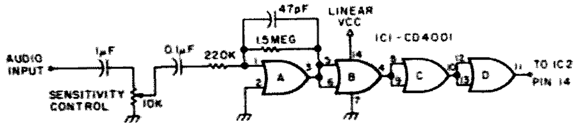

Fig. 9(a). Input amplifier and wave shaping.

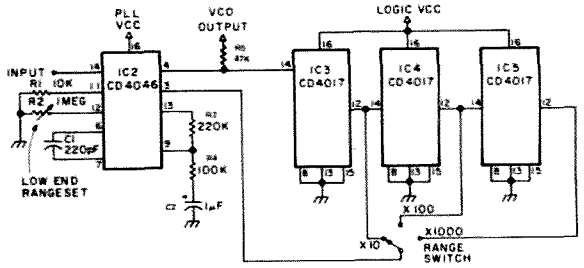

Fig. 9(b). PLL and logic for multiplier.

frequency end and R2 is used to set the low frequency end. Dc from the phase comparator output at pin 3 is filtered by R3, R4, and C2, and is fed to the VCO control terminal, pin 9. The VCO output at pin 4 is fed to the output connector through R5, which prevents loading of the VCO by the external frequency counter.

The output level is 5 volts peak-to-peak into an open circuit. IC3, 4 and 5 are each ÷10 circuits. Since the VCO tuning range is 20 kHz to 200 kHz, the output of IC3 feeds a 2 kHz to 20 kHz signal back to the phase comparator (pin 3) when S1 is in the x10 position. In this configuration, a signal in the range of 2 kHz to 20 kHz fed through the input amplifier is multiplied 10 times at the output terminal. Similarly, having S1 in the x100 position results in 100 times multiplication for inputs of 200 Hz to 2 kHz. And the x1000 position multiplies 20 Hz to 200 Hz signals by 1000.

Dc power is provided by the power supply of Fig. 9(c). A 9 V transistor radio battery is the prime source. This voltage is reduced to a regulated 5 volts by Q1, Q2, D1, and associated resistors. This is a pretty good regulator, by the way, for currents up to 20 mA or so. It stays in regulation until battery voltage drops to about 6.5 V, and is usable at inputs up to 20 volts. Decoupling is provided by the two 47 Ohm resistors, the 0.1 uF capacitors and the 5 uF capacitor, preventing interaction between the ICs through the Vcc lines. You may wonder why I used a discrete regulator rather than one of the new three terminal IC devices. Well, that's easy: a) I had the parts; and b) the IC versions don't work well at low current. Since the total circuit current drain is about 5 mA, I built my own regulator. The regulator circuit is copied from a design used in some industrial control equipment, so I claim no originality.

Construction

This is one project that does have critical parts layout. As I mentioned earlier, CMOS in logic circuits is noise immune, but CMOS in linear circuits is noise susceptible. The input amplifier and the IC2 wiring must be cleaner than the rest of the circuit. Point-to-point wiring on 0.1 in. x 0.1 in. vectorboard is fine, so long as the leads are kept short and direct. If you're ambitious, a PC board would be excellent. In any case, keep the wires with steep-sided pulses from the logic dividers away from the small-signal wiring of the input stages. Wiring of the divider stages and power supply regulator doesn't require any special precautions. In addition, it's a good idea to wire the audio input and VCO output lines with shielded cable to minimize any unwanted coupling. For guidance purposes, Fig. 10 shows the layout of the most recent point-to-point wired version. If you're ambitious and want a really neat construction job, a PC board version would be ideal – but so far I've been too lazy to build this multiplier that way. Incidentally, a metal cabinet is preferred as an enclosure to provide shielding, particularly if you plan to use the device around a transmitter.

Parts

In choosing parts for this project, I relied heavily on my junkbox. Admittedly, mine is probably better stocked with modern components than those of many other hams I know, but this is true only because I'm a hard core scrounger. I'll give you a few ideas about what components to use, but feel free to try those you have. If you substitute intelligently, your parts will work as well as mine.

The only really critical capacitor is the 220 pF capacitor used for VCO tuning. An ordinary disc ceramic will probably drift too much, even with the usual room temperature changes, causing the VCO lock range to vary from day to day. You should use a dipped mica or polystyrene capacitor for best results. The 1 uF input coupling capacitor should have paper or mylar dielectric and be rated at 100 V or so, since often you don't know what dc voltage you'll put on it making frequency measurements. The other capacitors of 1 uF or larger rating can be any electrolytic or tantalum types rated at 6 volts or more. All remaining capacitors can be disc ceramic types with 12 volt or higher voltage ratings. The CA4001 (IC1) and CD4046 (IC2) were purchased from James Electronics (a *73* advertiser) at reasonable cost. IC3, IC4 and IC5 are also available from James, but I took a cheaper route. The local Radio Shack store has been selling IC divider assortments for $1.98 (cat. no. 276-1607). They claim to be 100% functional devices, although I found a reject rate of about 20%. At any rate, several packs of them contained one good 7490 (a TTL device not used here), and several CD4017 and CD4018 devices each. For less than $4.00 (excluding tax), I got enough ICs to build two multipliers. Please note that the schematic in Fig. 9 shows the wiring for the 4017 dividers; if you have 4018 units refer to the RCA *CMOS Databook* for the correct wiring. If you are brave, try the Radio Shack assortment. If not, the devices are available from James and others at low cost. I recommend using sockets for all of the ICs. They often cost as much as the ICs themselves, but they make initial checkout and future troubleshooting much easier. The input potentiometer is a sensitivity adjustment; thus a panel-mounted control is most convenient. The VCO range pot, R2, can be a single turn PC mount device because its setting is not touchy. The remaining resistors can be ¼ or ½ Watt 10% carbon composition. The schematic shows a 1N5231 for the power supply zener diode. You can use any other ¼ Watt to 1 Watt device. The two transistors used in the regulator are not special. I've built this regulator in dozens of projects, and any NPN small signal silicon device such as 2N5172, 2N2222, 2N3394, 2N3904, or 2N4401 has worked equally well at this voltage and current level.

Checkout and Adjustment

When I designed the multiplier, I tried to make it as easy to build and use as possible. Ditto for adjustment. When you have it all assembled correctly, connect power, turn it on, and check

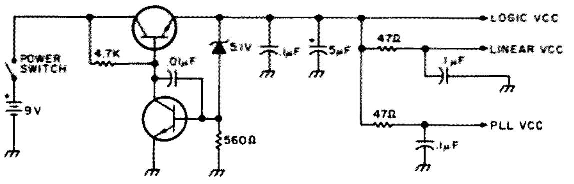

Fig. 9(c). Power supply regulator.

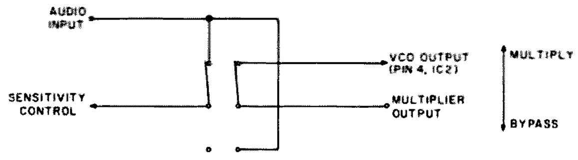

Fig. 9(d). Bypass switch wiring.

the power supply voltage at pin 14 of IC1 and pin 16 of IC2, 3, 4, and 5. When ail is well, it should be between 5 and 6 volts. If not, disconnect power and check your wiring. Should you have any remaining problems, the simplest troubleshooting method is to remove the ICs one at a time while checking the Vcc line. Incorrect regulated voltage with all of the ICs disconnected means a gross wiring error or bad components in the regulator.

When all is well powerwise, connect a frequency counter to the VCO output. Temporarily short circuit pin 9 of IC2 to ground. With pin 9 at ground, the VCO free runs at the low end of its range. You should be able to adjust the VCO frequency as read on the counter, with R2. Set the low end frequency at about 15 or 16 kHz. Now connect pin 9 to Vcc. This puts the VCO at its upper end, which should be 200 kHz or higher. If it is not between 220 and 280 kHz, change the value of Cl slightly — more capacitance for lower frequency and vice versa. After either adjustment, check both ends of the VCO range to make sure there is some overlap (low end less than 20 kHz and upper end above 200 kHz). In my prototypes, any CD4046 I've tried will fall easily within the above limits.

Now you can make an operational check. First use a 60 Hz source, such as the output of a filament transformer. *Do not* use the ac line directly. The multiplier won't be damaged by ac up to 20 V rms or so, but you can be severely fried playing with the ac line. First, connect the frequency counter to the ac source directly to verify the presence of 60 Hz ac. Then connect the counter to the multiplier output and the ac source to the multiplier input. Set the multiplier range switch to the x1000 position. By adjusting the input level control, you should be able to get the multiplier to lock on, causing your counter to read 60000. The input level control is not at all critical above some minimum setting. Once you've gotten this far, it's probably best to get hold of a signal generator and check the multiplier over its whole range of 20 Hz to 20 kHz. Should you have difficulty getting the device to function properly, a good oscilloscope is invaluable, and the aid of a friend familiar with digital circuits is recommended.

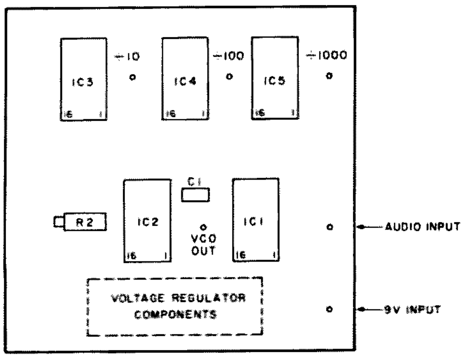

Fig. 10. Frequency multiplier parts layout.

Usage

A prescaling multiplier is a valuable addition to an ordinary frequency counter for fast, precise measurement of audio frequencies. Fig. 11 is a typical test setup for measuring the frequency of an audio oscillator. To set the multiplification factor of the prescaler, you must first know the approximate frequency of the signal being measured. To measure this quickly, set the prescaler's INPUT switch to the BYPASS position, so that the signal will go directly to the frequency counter. Taking note of the frequency, set the RANGE switch to the appropriate position. (For signals from 20 Hz to 200 Hz, use the x1000 range, for 200 Hz to 2 kHz use x100, and for 2 kHz to 20 kHz use the x10 setting.) You'll remember that there is some overlap in the ranges from the VCO tuning adjustment mentioned earlier. Now set the INPUT switch to the MULTIPLY position, turn the unit on and turn the SENSITIVITY control clockwise. If the signal is greater than 50 mV or so, the prescaler should lock on in several seconds and the frequency counter will read the oscillator frequency scaled up according to the multiplier setting. Thus, with an input signal of 50 Hz and the RANGE switch set for x1000, the VCO output is 50,000 Hz. With the frequency counter's timebase at 1 second, it will read 50000. Set at .1 second we get 5000, for .01 second 500, and finally, for .001 second the display reads 50. So by setting the counter timebase, you can tradeoff measurement resolution for faster updates. This makes setting the oscillator frequency much easier.

Final Comments

This has been a multipurpose article. Its overall purpose has been to present the circuit for a unique piece of test equipment. But, in addition, I've thrown in some theory and a bit of the background on how the device was conceived and implemented. Hopefully, it will prove valuable to brainy types who could come up with a similar gadget given enough time, and also maybe it will give some incentive to the average home builder who hasn't successfully gotten through the design of any modern circuitry. Whatever your background, I hope the article has been interesting and informative. At any rate, the frequency multiplier is easy to build and an extremely useful addition to any frequency counter. ■

Phone Patch Tips

-- a lost art?

Donald H. Johnson WB6MXD
943 Cameron Court
Arroyo Grande CA 93420

Here are a few tips for you home brewers who have tried to build phone patches from scratch parts which for one reason or another never quite turned out right. I've built quite a few, and these are some tips I think you will find helpful.

The first problem is to connect the speaker to the phone for the person on the other end to hear. Then we have to connect the phone line to the transmitter. This can be done in a number of ways. One of the simplest is shown in Fig. 1. It is fairly common to find such a transformer on the surplus market, and it makes a quick and easy phone patch. I have one with a 500 Ohm, a 50 Ohm and a 50,000 Ohm winding. It works quite well, but it does have its drawbacks.

In the very simple patch the audio from the speaker is always connected to the phone line, so you must mute the speaker completely when you are transmitting. Any hiss in the receiver output will be transmitted along with the voice of the person on the other end of the patch. Also, when you are in the receive mode the receiver output is crammed back into the transmitter. This means that it will be impossible to operate VOX. In fact, some transceivers may share audio sections with transmit and receive, and this loud signal into the mike jack may crossover into the receiver section. A simple solution is to get a DPDT switch and use it to key the transmitter and mute the mike as in Fig. 2.

If you would like to avoid the hassle of having the switch or perhaps would like to be able to operate VOX, you want to go to a hybrid phone patch. There are several different types of hybrid phone patches. The hybrid patch usually uses one or two transformers (coils) which are connected in such a way that the signal from the receiver is coupled to the phone line but is cancelled by an opposite signal in the lead that goes to the microphone. Attenuation in a good hybrid is typically around 40 dB, or about one one-hundredth of the receiver output gets to the transmitter.

In the one coil hybrid in Fig. 3 the flux set up by the speaker winding in the transformer core produces a voltage across the secondary windings and across the phone line. Notice the capacitor. This keeps the dc from the phone line from flowing through the transformer windings and saturating the core. If this happens the transformer will behave unpredictably and most certainly will not give you a good null between speaker and mike. Now if we look carefully at the mike winding we see that when current enters the speaker winding (with the dot) it leaves through the mike winding with the dot making the ends of both windings positive. The voltage across the mike winding bucks the voltage across the speaker winding, so the speaker audio will be cancelled in the mike output. However, when a signal comes in from the telephone it sets up a flux in the transformer core which seems to set up the same situation for cancellation as the previous situation. Actually it does not. The secret is in the 430 Ohm resistor and the fact that the signal is coming from the phone line rather than the speaker. In this case the current from the speaker is flowing through the 430 Ohm resistor in the opposite direction. And so instead of bucking each other they add, and the signal gets through.

Fig. 4 shows a typical two coil hybrid. It achieves its nulling effect by using the two cross connected number 1 windings. The 2.15 uF capacitor and the 900 Ohm resistor are typical values for nominal telephone line impedance. To get the best match you could put a capacitance meter across the line and find the exact capacitance of your line and then use a variable resistor to find the best null between speaker and mike. One important thing to remember when adjusting the null or "balance" is that you should place a call to a friend when you do so. Your telephone line impedance looks different after you complete a call. The phasing on the number 3 windings are different for each installation depending on how many phase inversions take place in the audio sections of your rig. Flipping one of the leads over might help you get that extra couple of dB isolation if your patch doesn't quite work as well as you would like on VOX. But for the most part the phasing is unimportant. Otherwise T1 and T2 are identical hybrid type transformers. The capacitors "C" are both identical non-electrolytics about 1.0 to 2.0 uF.

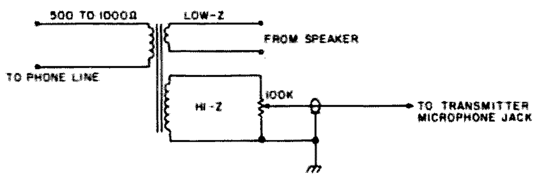

Fig. 1. Single transformer as a simple patch.

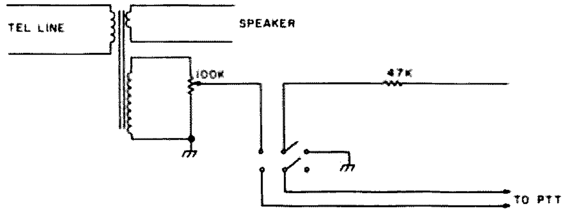

Fig. 2.

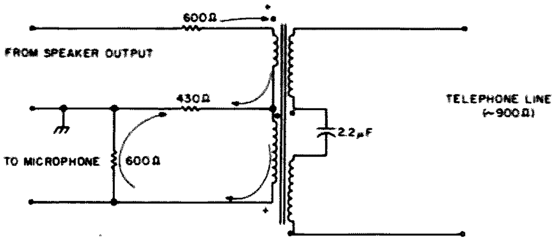

Fig. 3. One coil hybrid.

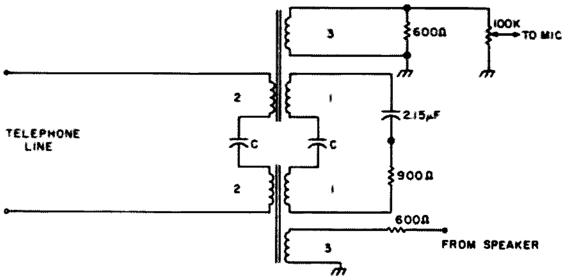

Fig. 4. Two coil hybrid.

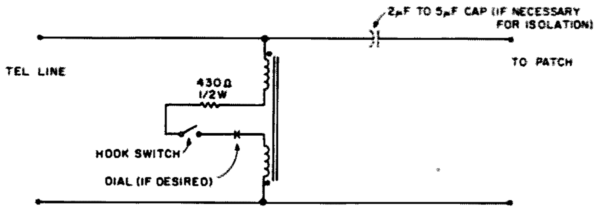

Fig. 5. Retard coil.

Again, it is very important to keep dc off the windings. But it is also necessary to provide a path for dc to keep the phone company equipment from seeing an off-hook condition and hanging up the phone. This can be done by simply keeping your phone off the hook, but any noise in the shack seems to come over much louder than the person on the other end of the picture. You could just slap a 500 Ohm resistor across the line, but that loads the patch. You have to crank up the gain, and you unbalance your hybrid if you are using one.

The phone companies have a real slick and simple solution for this problem. They call it a retard coil. All it amounts to is a 1:1 transformer with its windings set up to buck each other. Fig. 5 shows how a 1:1 transformer would be wired to act as a retard coil. By placing a switch in the center of the two windings you can go on or off hook as you desire. Place a dial in series with the switch and you can dial right from your patch. I have one set up like this, and it really works well. The resistor limits the current you draw from the line to a safe value. If your old homemade patch relies on current flowing through the patch transformer to hold it off hook put a 2 to 5 uF capacitor in series with your patch and try a retard coil to hold it. I'm sure you will find an improvement in frequency response. I used a cheap little 500 Ohm to 500 Ohm transistor transformer and it works fine.

Once you can hang up your phone during the patch you need some means to monitor the conversation so you can throw the switch or retune the receiver if necessary. Earphones work fine but you have to be careful about loading the line. Put a 0.1 uF capacitor (or larger) in series with a 2.2k resistor to your phones. Stereo headphones work quite well. Just connect the right and left channel in series by just using the two tips on the jack. No connection to the common or ground side is necessary. This works quite well and affords the people on the patch a little more privacy, or so it seems. (See Fig. 6.)

Store bought phone patches have nice meters on them to monitor audio levels. Regular VU meters are a little on the expensive side but they give a good indication. However, I chose to use one of the cheaper level meters you see advertised in ads in this magazine for $1.50 or $2.00. I ordered a couple from Poly Paks and found that they are about 140 uA full scale with 100 uA being about "0 VU." Plenty sensitive but they are dc meters. I used a diode bridge to rectify the audio. I used four germanium diodes and made it myself. Be sure you have germanium diodes. Their lower forward voltage drop (0.2 V instead of 0.6 V for silicon) makes them preferable for rectifying low voltages. Fig. 7 shows the finished meter circuit. The resistor R is a fixed resistor that is chosen experimentally to give the desired meter deflection. Again I urge you to keep it on the large side. If 3.3k and 3.9k both look pretty good choose 3.9k. This is best chosen by calling someone and having them tell you when the signal from the patch sounds like a comfortable listening level. Then change resistors until the meter peaks around two-thirds of the way up the meter face. You may want to put a switch in series with the meter circuit, so it will not peg out when you are dialing or when your phone rings.

Which brings up another interesting idea. If you are hard of hearing or have a high noise level in your shack and have the bell on the telephone in your shack turned down you can see your telephone ring by hooking a neon light across the line. The ac ringer voltage will light the light when the bell rings. Don't forget to put a current limiting resistor in series with the light. It can be a small light or a larger one that can be seen for quite a distance. (See Fig. 8.)

It's always a good idea to keep rf out of your patch and the phone lines. Fig. 9 shows a brute force type line filter. The ground shown should be a good earth ground. If you get rf into your meter try a 0.01 uF ceramic type capacitor across the terminals.

Following these tips and with good construction practices you should be able to come up with a very good phone patch that you can be proud of. Just remember to keep dc currents from flowing through your patch transformer. If nothing else put a 2 to 5 uF capacitor in series with the winding. Try the retard coil gimmick and phones, and see if the people you patch together don't like it much better. ■

Impedance Matching

-- simplify a complex process

Mark E. Pecen WB5HEQ
18 Willow Creek Place
Richardson TX 75080

In designing an antenna system or matching network, a radio amateur many times finds the need to measure the actual complex impedance of a transmission line, antenna, or network at the rf operating frequency. This can be done simply and accurately by using a directional wattmeter and various lossless mismatches constructed from capacitors, without the expense of measuring equipment such as network analyzers and RX bridges costing upward from several thousand dollars.

Materials Needed

– A directional wattmeter having the capability to measure forward and reflected power at the operating frequency. An accurate vswr meter may also be used.

– Transmitter or exciter capable of transmitting a CW signal at the operating frequency with enough magnitude to properly operate the power meter or vswr bridge. (The output impedance of the exciter should be equal to the characteristic impedance of the transmission line being used; in most cases, 50 Ω for amateur applications.)

– A dummy load of proper resistive impedance and power dissipation characteristics to terminate the output of the exciter, having a vswr of not more than 1.2:1 (not more than approximately 1% reflected power). The closer the load is to a 1.0:1 match, the more accurate the impedance measurements will be.

– Capacitors, silver mica, not less than 500 WV dc (see text).

– Coaxial cable for connection of the exciter to the input of the wattmeter or vswr meter, having a characteristic impedance of that of the exciter (usually 50 Ω for amateur applications).

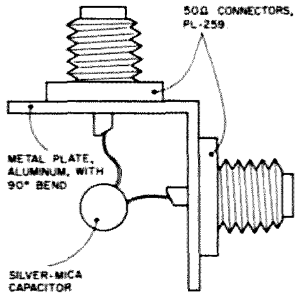

Fig. 1. Construction of capacitive mismatches for impedance measurements.

Construction of the Capacitive Mismatches

The capacitors used should provide an imaginary impedance of approximately -j0.5 to -j3.0 at the operating frequency. This means that the range of reactance of the capacitors used can be from $0.5Z_0$ to $3.0Z_0$.

In a 50 Ω system,

$0.5Z_0$	$3.0Z_0$
= 0.5(50 Ω)	= 3.0(50 Ω)
= 25 Ω	= 150 Ω

So, the capacitive reactance can range from 25 Ω to 150 Ω at the rf operating frequency for a 50 Ω system (see Table 1).

Calibration Procedure

1. Construct measurement circuit as shown in Fig. 2. Select two capacitors that fall in the proper capacity range for the frequency at which the impedance measurement is to be made.

2. Measure and record the vswr of the load with each capacitor in the circuit. If the wattmeter used does not have an swr scale, refer to Fig. 3.

3. Draw a constant vswr circle on the Smith chart for each of the vswr measurements taken with the capacitors in the circuit.

4. Find the point along the resistance circle, R=1, where intersection with each of the constant vswr circles occurs.

5. Record the value of each of the reactive components at the points of intersection, (-jX). These values are the reactive values of the capacitive mismatches that are to be used in measuring complex complex impedances at the rf frequency at which the calibration was made.

Impedance Measurement

1. Construct measurement circuit as shown in Fig. 4. Measure and record vswr of the load.

2. Construct measurement circuit as shown in Fig. 5. Measure and record the vswr of the load in series with each of the capacitive mismatches.

3. Plot and label the vswr circles of the measurement of the load vswr and the vswr of the load plus each of the series mismatches.

4. Find the resistance circle on which △jX (the change in jX) between the load vswr circle and the load-plus-mismatch vswr circles is equal to that of the value recorded for each value of -jX recorded in the calibration measurement.

5. Follow the resistance circle to the point where it intersects the vswr circle of the load only. This point of intersection is the value of the complex impedance of the load, R + jX.

Example

The frequency at which

Amateur Band	-j0.5	-j3.0
80m	1700 pF	280 pF
40m	890 pF	150 pF
20m	450 pF	75 pF
15m	300 pF	50 pF
10m	220 pF	37 pF

Table 1.

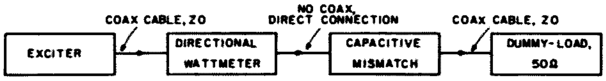

Fig. 2. Measurement circuit for calibration of the capacitive mismatches at the rf operating frequency.

$$\text{swr} = \frac{1 + p}{1 - p}$$

$$p = \log 10^{-1} \left(\frac{10 \log 10 \left(\frac{P_{forward}}{P_{reflected}} \right)}{-20} \right)$$

Fig. 3. Conversion of forward and reflected power to vswr.

Fig. 4.

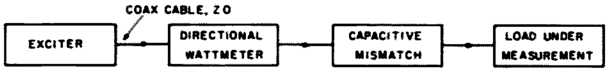

Fig. 5.

the impedance measurement is to be made is 14.250 MHz.

The value of the capacitors in the two capacitive mismatches, ZX_1 and ZX_2, equals:

Capacitor, ZX_1 = 400 pF
Capacitor, ZX_2 = 120 pF

Calibration (50 Ω system)

1. Measurement circuit in Fig. 2 was constructed. Two capacitors were selected for use in the capacitive mismatches, corresponding to the limits specified in Table 1.

2. The vswr of the dummy load plus each of the capacitive mismatches was measured and recorded.

vswr, ZX_1 + load = 1.8:1
vswr, ZX_2 + load = 5.2:1

3. Constant vswr circles were drawn for each measurement. See Smith chart A.

4. The points of intersection with the R=1 resistance circle were found and labeled, points A and B.

5. The value of each of the reactive components of ZX_1 and ZX_2 were recorded from points A and B of the Smith chart.

ZX_1 = -j0.62
ZX_2 = j1.85

Impedance Measurement

1. The measurement circuit in Fig. 4 was constructed. The vswr of the load was measured and recorded.

vswr, load = 2.5:1

2. The measurement circuit in Fig. 5 was constructed. The vswr of the load plus each of the capacitive mismatches was measured and recorded.

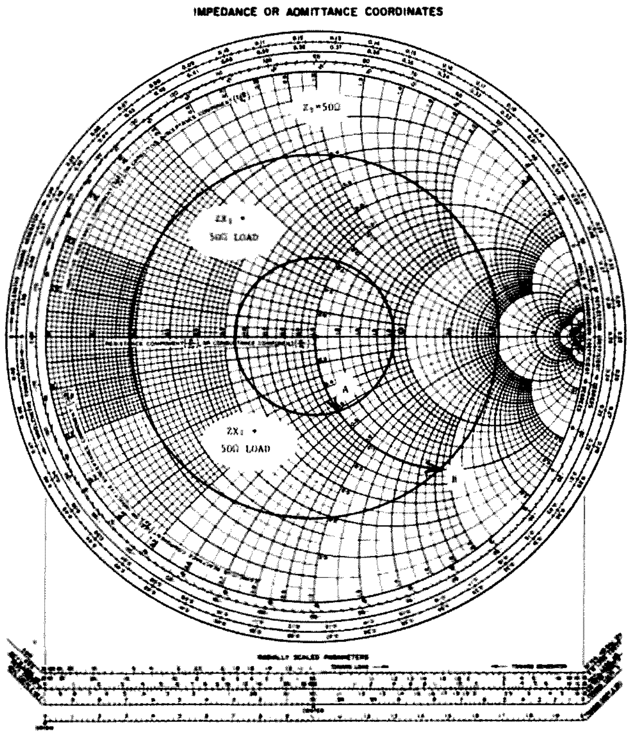
vswr, load plus ZX_1 = 1.78:1

vswr, load plus ZX_2 = 5.2:1

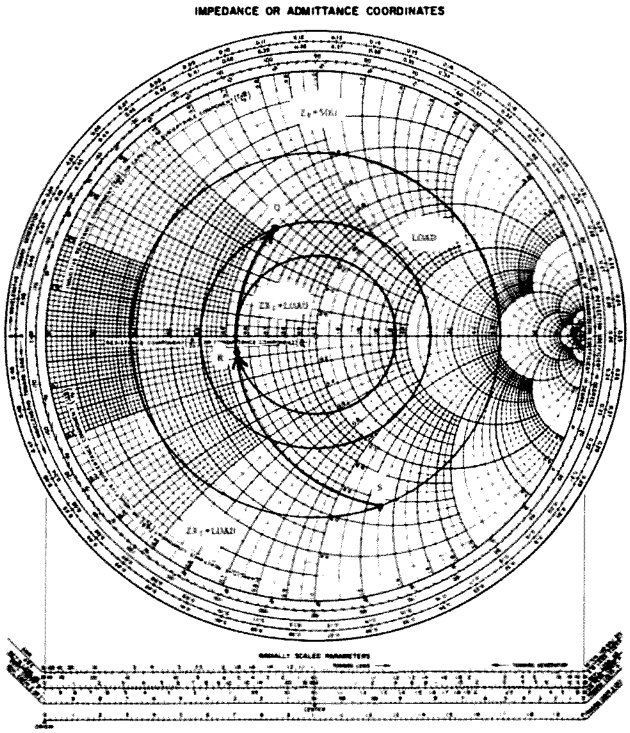
3. Constant vswr circles were plotted for the measurement of the load vswr and the vswr of the load plus each of the series mismatches. See Smith chart B.

4. The resistance circle on which $\triangle$jX between the load vswr circle and the load-plus-mismatch vswr circles is equal to that of the recorded value of -jX found in the calibration measurement located on Smith chart B. $\triangle$jX between points Q and R = (-j0.62) = 0.62. $\triangle$jX between points R and S = (-j1.85) = 1.85.

5. The $0.55Z_0$ resistance circle is drawn from point S to point Q, as indicated by the arrow. Point Q lies on the vswr circle of the load only, so point Q is equal to the value of the complex impedance of the load, R + jX. So, the load impedance = 0.55 + j0.55. ■



Smith Chart A.



Smith Chart B.

Looking West

from page 33

people like Ernie for the time spent updating us, and sincerely hope that this kind of information flow will continue.

As you are aware, part of the trip from here on was spent both SWLing CB and QSOing a "Ham Trucker" into Santa Barbara (on both CB and via two meters). It was not long after that, while listening on .28/.88, that the voice of Larry WA6OBT was heard on the Sulphur Mountain, Ventura County Repeater (WR6AOX). That meant that home was but an hour away. I hope that you enjoyed this trip along with us; maybe soon we can do it again. I can tell you that I will have some updated information this fall, since I intend to accept Ernie's invite and will definitely be at the Santa Maria Convention in October. I've heard that the barbecue is something to behold . . .

"73 AND 55"

"WA6ITF clear WR6BAX – 73 and 55, everyone." Something like that is being heard a lot out here these days on both HF and on our VHF repeaters. In fact, 55s are coming from as far to the west as Korea, according to Lenore Jensen W6NAZ. The Los Angeles Council of Radio Clubs, acting in cooperation with the California Highway Patrol, has hit upon a way in which amateurs can actively participate in a program designed to conserve two of this nation's most important natural resources: fuel and people.

When CHP Officer Dean Hirst came to my place of employment not long ago to speak on the subject of the Highway Patrol's renewed effort to motivate voluntary compliance with the national speed limit of 55 mph, and brought forth incontrovertible proof that the ten mile per hour reduction in the speed limit (from its previous 65 mph) had substantially lowered the number of fatal accidents in this state, it occurred to me that amateur radio might just be the proper vehicle to help spread the word. After all, the life saved might be yours, mine, or that of one of our loved ones.

A subsequent conversation with Officer Hirst led to an introduction to Southern California ARRL P.R.A. Lenore Jensen and to a meeting with the Los Angeles Council of Radio Clubs. Out of the final step has come a pledge that amateur radio operators will do all they can to adhere to the 55 mph limit and to help spread the word of the dual savings by ending QSOs with "73 and 55," thus signifying the individual pledge of voluntary compliance.

Whether you believe that there is a real energy crisis or are one of the skeptics is not important. The fact that the lower speed limit saves lives has been proven, and that in itself is more than enough reason for my own compliance with it.

How about you? Want to help make this a national movement within amateur radio? It's easy: just watch your speedometer and spread the word by using "73 and 55!"

Officer Dean Hirst of the California Highway Patrol and Mary Ed Killitz WA6EJP of the San Fernando Valley Amateur Radio Club.

Social Events

SWIFT CURRENT SASKATCHEWAN JULY 2

There will be a hamfest held at Swift Current, Saskatchewan on July 2, 1977. For more info contact H. Bassendowske VE5PZ, 1433 Taylor Drive, Swift Current, Saskatchewan.

MILTON ONTARIO JULY 8-10

The Ontario Hamfest '77 will be held on July 8, 9 and 10, 1977, at the Milton Fairgrounds in Milton, Ontario. Program includes numerous commercial displays, giant flea market (no space charge), auction late Saturday afternoon, CW bingo, prizes and ham displays. Registration $4.50 adults; $3.00 children; children under 3 no charge. Registration after June 15 will be $5.00 for adults. All activities will be held inside in the event of rain. Talk-in station on 146.520 MHz simplex. For more information write Burlington Amateur Radio Club, PO 836, Burlington, Ont. L7R 3Y6.

OAK CREEK WI JULY 9

The South Milwaukee Amateur Radio Club Swapfest '77 will be held Saturday, July 9, 1977 at Shepard Park (American Legion Post #434), 9327 South Shepard Avenue, Oak Creek, Wisconsin. Activities begin at 7 am and will run until about 5 pm. Parking, picnic area, hot and cold sandwiches and liquid refreshments will be available on grounds. Overnite camping is available. Admission is $1 and includes a "Happy Hour" with free beverages. Prizes will be awarded. Talk-in on 146.94 MHz FM. More details (inc. map) from: South Milwaukee Amateur Radio Club Inc., S. F. Schreiter W9AKF, Sec., 104 Brookdale Drive, South Milwaukee WI 53172.

CUMMINGTON MA JULY 9-10

The Northern Berkshire Amateur Radio Club Hamfest will be held July 9th and 10th at the Cummington Fairgrounds, Cummington MA. Free overnight camping, tech talks, demos., and dealers. Flea market $1. Admission $3 with XYL $5, advanced $2 and $4. For information write Hildy Sheerin WA1ZNE, 79 Greylock Ter., Pittsfield MA 01201.

CHARLESTON SC JULY 9-10

The Charles Towne Hamfest, Charleston, South Carolina, will be held on July 9 and 10, 1977. Saturday, July 9th, the Charles Towne Hospitality Room will be at the Heart of Charleston Motor Inn starting at 7:30 pm. Sunday, July 10th, the flea market and swapfest will be at the Gaillard Municipal Auditorium starting at 8 am. Complete details by writing to: Charles Towne Hamfest Committee, Box 4555, Charleston Heights SC 29405.

INDIANAPOLIS IN JULY 10

The Sixth Annual Indianapolis Hamfest will be held on Sunday, July 10, 1977 at the Marion County Fairgrounds. There will be hourly prize drawings, a main prize drawing, a large indoor flea market, and a large outdoor flea market, forums, etc. Over 100 campsites are available. Forty with full hook-ups. Gate admission: $2. For more information write Indianapolis Hamfest, PO Box 1002, Indianapolis IN 46206.

BROOKLYN NY JULY 10

The Kings County Repeater Association of Brooklyn, New York, will hold its annual outdoor flea market (if rain – indoors) on Sunday, July 10, 1977, at 9 am to 4 pm. Located at 17 Eastern Parkway (at Grand Army Plaza), Brooklyn, New York. Sellers $6 per table, $3 half table, buyers $1. Refreshments available. Talk-in on 147.43, 146.43 and 52 direct. For further information contact WA2UMY (212) 941-8780.

SARATOGA UT JULY 16

The Utah Amateur Radio Club will hold its annual Utah hamfest and steak fry on July 16th at Saratoga resort. Bill of fare includes swap tables, CW contest, home brew contest, Oscar demo, women's activities, steak fry and many more ham games. Registration is $2 for UARC members, $5 for non-members and $1 for children under twelve. Registration includes choice steak, discount on rides, hot dog for kids, drawings and all other activities. Events begin at 9 am and run until after dark. Talk-in on repeater 16/76. For more information contact John Dehnei, c/o Utah Amateur Radio Club, 1547 Redondo, Salt Lake City UT 84105.

CORUNNA MI JULY 16-17

The Shiawassee Amateur Radio Association (SARA) is hosting the Buzzards Roost, Michigan Emergency, and Wolverine Nets picnic and SARA's 3rd Annual FREE Swap and Shop, Saturday and Sunday, July 16 and 17 at McCurdy Park in Corunna, Michigan just east of Owosso. Swap and Shop tables and trunk sale spaces available at $2.00 for 1 day and $3.00 for 2 days. Talk-in with W8QQO on 3930 kHz, 146.52 MHz, 147.63/03 repeater, 449.3/442.1 MHz repeater. For a flier with a map and further information write: SARA, W8QQO,

Digital Clock Fail-Safe

-- so you won't miss the train

Honey, what time is 88:88:88?" "Oh, oh! You pulled the plug. Find out what time it is and I'll reset the clock." "Sorry I'm late, Boss. There must have been a power failure during the night and my electronic digital clock was talking garbage this morning." "Every time I close the transmitter key, that fool clock jumps two hours!" Situations sound familiar? Sure do, but this doesn't have to be. The fact is that of the three basic types of clocks, electrical, mechanical, or electronic, the latter is the one most easily made fail-safe. The trick is to get a little extra filtering in the normal ac to dc power supply and to provide a standby source of dc voltage and a 60 Hz (50 Hz) signal to keep the clock counting during a power outage.

For a clock built around the CT7001 or similar chip, there's no problem. Beef up the filtering a bit, add a backup battery supply with some diode switching, and let the built-in oscillator provide the counting signal. The ac/dc power supply shown in Fig. 1 should do the job nicely. For almost any other chip, however, an off chip oscillator has to be provided as well as the battery backup.

One way to generate the reference signal for the counting circuit is to use a precision crystal oscillator coupled with a suitable frequency dividing circuit. There are several ads in this magazine for just such circuits, prebuilt or in kit form. But if your clock is normally operated from the ac mains, the crystal oscillator is only the more expensive, not the best, approach to keeping reasonably accurate time. In the long run, the 60 Hz (50 Hz) signal provided by the power company should average out to a much more accurate count than will even a well-compensated crystal oscillator. It is possible to synchronize the crystal oscillator to the power company line frequency. However, this generally is not done in the known available kits and, even if it were, it would be an unnecessarily expensive solution.

An alternative technical approach is shown in Fig. 1. It is considerably less expensive than the crystal oscillator/divider circuit and is inherently as accurate as the power company's line frequency whenever ac power is available. As long as the power company keeps furnishing the ac voltage, this oscillator will remain synchronized to the line frequency.

The circuit consists of an ac and backup battery power supply, some switching diodes to automatically engage the battery only when the ac voltage fails, and a phase-shift oscillator that will either synchronize with the line frequency or, during power outage, will provide a reasonably accurate signal to keep the clock counting. The "tickler" coming from the secondary of the power transformer to the base of Q1 serves to lock the oscillator to line frequency, working best when the resonant or free-running oscillator frequency is slightly low, even if ever so slightly. Only during a power outage will the resonant frequency of the oscillator determine clock accuracy.

Will the fact that the free-running oscillator is slightly slow cause much of a problem during power outage? Not really. Let's assume that it runs at 59.9 Hz and also that we have a reasonably long power outage, say four hours. The 0.1 Hz error translates to a 0.167% error, the clock losing 24 seconds during the power outage.

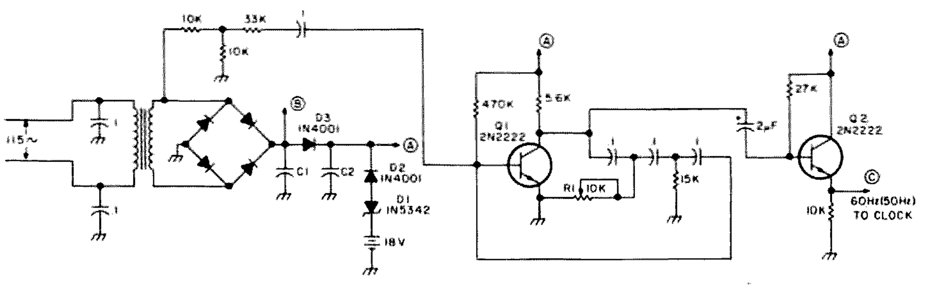

Fig. 1. Fail-safe power supply and clock count generator. Notes: 1. C1 = C2 = 200 to 300 uF, 25 volt; 2. D1, D2 — see text; 3. Adjust R1 for 50 or 60 Hz; 4. Point B to LED supply (see Fig. 2); 5. Resistors ¼ or ½ Watt, as available.

That shouldn't be upsetting in most cases.

Emitter follower, Q2, isolates the oscillator from the clock chip load and provides the necessary current sink. It, like Q1, is shown as a 2N2222. Actually, almost any small silicon NPN transistor will do either job. This looks like a great place to use some of those house-numbered transistors salvaged from a surplus board!

In the typical digital clock circuit, a signal is taken from the secondary of the power transformer, through a current limiting resistor (about 100k Ohms), to one of the clock IC's pins. A signal diode generally goes from that pin to the positive voltage supply. These components should not be removed. Simply cut the existing foil lead near the transformer secondary and solder a lead from the 60 Hz (50 Hz) output of the oscillator to the end of the current limiting resistor that formerly went to the transformer.

Providing a battery backup for the dc voltage to the clock chip may be a little more difficult on a previously assembled board than is coupling in of the timing signal. The actual complexity will vary from board to board, and all that can be said is, "It isn't really tough!" For new construction, whether using a "store bought" PC board or a "home brewed" one, it's probably best to use a separate board for the power supply and phase shift oscillator. If rebuilding an existing clock, it may be best to carefully salvage the power supply associated components from the old board and reuse them on a separate board. By the way, don't forget to remove the clock IC from the board while doing any soldering or unsoldering. It could save you the cost of a new chip!

Fig. 1 shows an 18 volt battery power supply made up of two 9 volt transistor radio batteries in series. The voltage is dropped 6.8 volts across a 1N5342 zener diode and another 0.6 or 0.7 volts through a 1N4001 before coupling to the ac power supply output (point A on Fig. 1). With the exception of the 1N4001 (or equivalent) diode that provides a switching function, nothing in the combination is critical. It is important only to have the battery-supplied voltage slightly below the normal ac-supplied voltage so as to prevent battery drain during normal operation.

Measure the dc voltage at the filter capacitor in your existing circuit. This will tend to fluctuate as the number of LED elements activated in the display changes. The highest value observed is the one of interest. From that value, subtract about 0.7 volts to account for the drop that will occur across diode D3. The battery voltage to be furnished to point A should be below the resultant figure and above the minimum operating voltage specified by the clock IC manufacturer. Within that range, any combination of batteries and voltage dropping diodes is satisfactory.

For example, the highest measured voltage at point A in the prototype was 12.5 volts. The clock chip specification called for an 11 volt minimum. Thus, any value between 11 and 12.5 volts would be satisfactory. The battery supply could have been made up of a 9 volt cell in series with two 1.5 volt cells with the zener eliminated. The actual circuit used was chosen because the zener was available and for ease in packaging the battery pack. Custom your package to fit your needs. Don't forget, however, that new cell terminal voltage for the 9 volt cell is about 9.4 volts and, for the 1.5 volt cell is 1.55 volts. If you cut your design too close, inadvertent drain of the battery supply during ac operation is possible.

The fail-safe circuit is designed so that, in principle, the LEDs will not display during battery operation. This is done deliberately to minimize battery drain. In some cases, however, the digits may be faintly displayed. This could occur with the circuit configuration shown in Fig. 2 if the LEDs are particularly efficient. The enabling current is base current flowing through the base of the NPN to the clock IC.

If your digital clock has an alarm clock feature and there happens to be a power outage at the instant the alarm should sound, the fail-safe circuit may or may not cause the alarm to function. It depends upon the design of the alarm feature. If there's an on- or off-chip oscillator, with or without an additional amplifier, driving a small speaker, the alarm buzzer can be made to function even though the time is not being displayed. It's necessary only to insure that power for the alarm circuit is tapped from point A and not from the LED supply bus. Obviously, if the clock functions to enable a radio-alarm, there won't be power available to play the radio, so... This does raise a good point, however. Should you have a radio-alarm, most likely the clock chip is driving a transistor which, in turn, pulls in a relay at the preset time. The relay can be a power hog. In order to protect the batteries, Vcc for the transistor that drives the relay should come from the LED supply bus.

The power supply of Fig. 1 has two filter capacitors, one on each side of diode D3. Capacitor C2 serves to further smooth the ac-supplied voltage against voltage transients. If the batteries are reasonably fresh, this capacitor isn't really necessary. It's most important as the batteries begin to age or are out of the circuit. It, like the zener diode, was a designer choice.

Calibration of the phase shift oscillator is most easily accomplished with the aid of an oscilloscope or frequency counter. With the latter, simply set the frequency to 59.9 Hz (49.9 Hz). For the scope, connect the vertical probe to the oscillator output, and the horizontal probe to the line frequency terminal on the scope or a similar 50 or 60 Hz source. Adjust R1 until a single ellipse (Lissajous pattern) appears. Then back off ever so slightly so that the pattern appears to be slowly rotating in a clockwise direction about an axis in the plane of the scope.

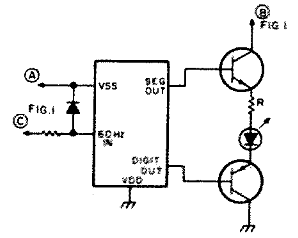

Fig. 2. Isolated LED supply and count in.

An alternative technique for calibration is with the sweep second hand of a watch or clock. Rig a temporary switch to enable and disable the ac line to the digital clock. Set the clock, turn power off for a period of 90 seconds, and switch power back on. Adjust R1 until the digital clock advances 90 seconds during the ac power off period. If, after a period of several days, the clock has gained time, tweak R1 to a slightly higher resistance. If the clock is four digit only, switch ac power off just as the minute digit changes. Delay 120 seconds and turn power back on. Adjust R1 so that, at first, the clock is running slow; the minute digit has not quite advanced again when power is reapplied. Gradually adjust R1 to decrease the error.

As the transformer used in the prototype was of the printed circuit board type, a simple PC board was used for the power supply and oscillator. It could otherwise just as well have been assembled on perfboard, vectorboard, or any other of the commonly used assembly techniques.

This simple fail-safe circuit works. Try it, you'll like it! ■

Interest In Mail Order?

-- an insight into facts and myths

No, this isn't an article about setting up a mail-order business; rather, the subject is how you, as a consumer, can get the most benefit from mail order. As partner in an ad agency, I've had the opportunity to talk with several mail-order companies, and see how they work . . . from announcing a product to shipping out orders. You should know about some of the things I've learned in the process, as this information will help you get the satisfaction you deserve out of mail-order businesses. First of all, let's dispel two myths about the mail-order business:

Myth #1: Mail Order is Unreliable. This used to be true, especially in the days of patent medicines and sure cures for gout. Now, however, the competition is tough enough that no business can afford shady operation or unsatisfied customers. Additionally, new federal regulations – plus the severity of postal fraud charges – keep a watchful eye over mail order in general; and finally, magazines stop carrying advertising of those companies that inspire complaints to the magazine. A deadbeat company reflects negatively on the magazine that carries the advertising and makes life difficult for the legitimate operators.

How often do you get taken? Over the past eight years I've ordered something from just about every parts company that popped its head up over the horizon. The only problem I had was with a certain company that advertised surplus Switchcraft jacks and ended up sending me Japanese imports (worth far less than the jacks I ordered), and 6 months after I had sent my order, to boot! They cemented my unkind feelings by refusing to answer my letters. Six months later, no magazine was carrying their advertising, which confirmed my opinion was shared by others.

This is not to say you won't have problems; mail-order business employees have bad days, too, and dumb days, and sometimes they misplace an order or give you the wrong part. But these mistakes are forgivable; after all, we all make them.

Myth #2: Mail Order Can Sell Cheap Because There Is No Overhead. True, there is no store. But there are employees, ad budgets, rents on warehouse space, office space, city taxes, state taxes, bookkeeping, repair services, bank charges, insurance, social security payments . . . and the list goes on. But the important point for you to remember is that all of these have to be paid out of the customer's order. We'll see why this is important as we go along, since your actions can make a company operate more efficiently, and help keep costs down for you and other customers.

Ordering

First, order from *current* ads and catalogs. Prices fluctuate; some items are constantly going up, some are constantly going down (seen any $350 8080s lately?) Also, terms of sale sometimes change as a company changes, and there is no set policy on shipping, which varies from company to company. Sending in an order with not enough or too much money slows things down and increases expenses, and guess who ends up paying for it? So it may seem like a small thing, but courtesy dictates that you not send in for a special advertised in April two weeks before Christmas. If you want to find out whether an item is in stock, or if you want to check price, a phone call (remember the new 1 minute rates) or a post card if you're patient will do the job. And, of course, you can always circle the reader service cards in this and other magazines to keep abreast of the latest catalogs.

However, there will be times when you need more information about a product before making an informed buying decision. Again, write or phone the company, but take a few thoughts into account. Keep your questions as specific and to the point as possible; if you waste the time of the people at the company, they will not be able to do what they're paid to do – tend to the orders of paying customers. In fact, if the question you ask is specialized ("I have an antique Atwater Kent and would like to know if your part #45A3 is equivalent to their part #6543"), it is a nice gesture to include a self-addressed, stamped envelope, with your question written out, and a space for the answer. Then the company gets your request, scrawls an answer, and it's back in the mail the same day. Otherwise, the secretary has to be pulled off writing invoices to handle your request, then postage has to be affixed, the address double-checked, and so on. Remember that your requests are being paid for by the customers, so be considerate.

Now you know what to order. Next comes . . .

The Order Blank

First, make sure your

name and address are on the order! It really gets a company bothered to have an order for $76 worth of parts and no idea of where to send them, or who ordered them in the first place. In a case like that, the only hope is that the customer will write in and ask what happened to the order. Having your address on the check is not good enough, because most companies, when the mail comes in, verify that the amount of the check jibes with the order . . . at which point the check is immediately rushed to the bank to begin the clearing process, while the order moves on to the packing department. It is almost impossible for a large company to go back through a week's worth of checks to weed out one address. For similar reasons, if you have correspondence or questions that don't pertain to the order, put them on a separate piece of paper. That way your question will go to the technical service people, the order will get packed, and the check will get safely put in the bank.

Next, use the order blank the company provides; if that's not available, then type or print up your own, making sure you include 1) the name and/or stock number of the item desired; 2) the quantity you want; 3) a brief description of the item; 4) the subtotal for this item. If applicable, you might put acceptable substitutes on the line below. After you've listed all your items and prices, add the subtotals together and you're in business. If you need to add extra money, for insurance, handling charges, state tax, or whatever, list what it is, clearly. Don't just add on $2 and expect the company to know what you're doing it for. Is it tax? Or maybe you're ordering two catalogs. Be specific! When a packer is faced with dozens, maybe hundreds, of little pieces of paper in a day, each one of which must be perfectly packed – anything you can do to help speed things up is greatly appreciated. And that includes neat handwriting, too.

One way to make a company happy is to reference an ad if you're buying from an ad. Now I know people don't like to do this – sort of the "why should I help them, they're taking my money" attitude – but this is poor strategy, and here's why. Advertising is the *only* way a mail-order company can promote itself; there are no walk-in sales. And, advertising is not cheap. The money a company pays for ads has to come out of the profits generated by selling goods. A company with a good, effective, simple advertising program can sell for less and make more money if they know where their ads are doing the most good. This in turn keeps costs down for you. Money wasted on advertising that no one orders from only raises the prices of items you want.

The Postage Problem

In the semi-good old days, postage was cheap and the living was easy. Not so any more. The cost of postage, particularly for something heavy like a power supply, can turn a profitable product into a money sucker . . . which gets passed on to you. So, more and more companies are requesting postage or just tack on a straight percentage to cover postage and handling. This brings up a pet peeve of mine: the credit slip. Luckily, these do seem to be dying a slow death, and, unless the amount is very small, most companies will write a refund check if you include too much money for postage. If you get a credit slip, you can always request a check and send back the slip. Xerox your letter and credit slip, though, just in case there are any problems.

More and more companies are relying on UPS to ship their packages. This generally gives better service than the PO, but remember that UPS goes to your house and needs a street address. They cannot deliver to a post office box, unless, of course, you happen to live in one (cramped quarters, but cheap rent). If you do not include a street address, there will be delays: First UPS has to check with the post office to see if you have a local street address; then they send out a notice that informs you that you need to call UPS and complete arrangements for the delivery of the package. Save time and hassle – include your street address and PO box if you have one (for the mailing list).

There is an easy way to find out exact postage charges. Let's say you're ordering a 10 pound widget from a company in Florida, and you live in Ohio, and the widget is being sent via UPS. Just call up your local UPS and ask them how much it would cost to send a 10 pound widget to Florida from Ohio. It costs the same whether a package goes from point A to point B, or from point B to point A.

Minimum Orders

Here is what appears to be a classic example of screwing the little guy, or at least that's what I always thought. But look at it from the company's point of view, and from yours . . . it only takes a little more time to pack a $200 order than a $2 order. Let's say it takes 30 minutes total to process a single order. This comes out to at least $1.50 worth of labor at today's wages. So in the case of the $200 order, there's enough profit to pay for the cost of the processing. But with a $2 order, the company may actually lose money. A company that loses money has to make up the difference somewhere, and that difference comes out of the pockets of customers. To help defray this, most companies tack on a service charge for orders under a certain amount. It's a drag, I know; there have been many times I wanted to buy a single IC, only to find out it would be cheaper to buy ten. But you can't really blame the companies, at least not until people are willing to pack orders for free. Meeting minimum orders keeps the cost down for everybody.

Complaints

Eventually you may have to complain about something. But before you do, simmer down for a second and look at the situation objectively. People are only human, and mistakes do occur. Before you assume that a company is out to do you in, give them the benefit of the doubt. Letters do get lost or misplaced; water can spill on an order and make the ink run to the point of illegibility; handwriting can be undecipherable; in short, Murphy's Law is no stranger to the mail-order biz. Or maybe the product that was scheduled to be shipped January 1 is missing two ICs, which were promised by the supplier to arrive in November and finally show up in March. Be sympathetic. The object of a complaint is not to vent your spleen, or to take your aggressions out on some poor clerk, but to get a problem resolved. Don't accuse someone of dishonesty when their only crime may be ignorance or carelessness. It happens to all of us. First time, state your problem clearly and unemotionally; ask for their explanation. But – and this is an important but – although the odds are against it, you may be dealing with a thief. If you make a complaint, make at least two copies of your correspondence in case you need to complain again to the company or the authorities. If you don't get any action after two or three weeks (which should be enough time for the company to answer you), your next letter should be a little less courteous. Mention the date of the previous correspondence, and

show them you've been patient. My father taught me an almost foolproof way of getting answers from people who don't answer the first letter: Take a carbon copy (this is why you make two copies), and write across it, in the biggest letters possible, DON'T YOU ANSWER YOUR MAIL? It gets results.

But if it doesn't . . . the company has two strikes against it. Now comes your "last straw" letter. Document your previous attempts (". . . there was no reply to my letter of October 2 or November 15 . . . ") and get mad; you've earned it. Send a carbon to the magazine handling their ads, the Better Business Bureau, and possibly someone at consumer affairs in their state government. By the way, you can almost always get a street address for a business from a magazine that carries their advertising; they can't hide behind a PO box anymore. Don't forget the action line of local papers, too; although they may not be able to help in your specific case, they can refer you to the proper authorities.

Postal fraud is a very serious federal offense, and if you can't get satisfaction after all this pressure, it's time to get the government into the act. No doubt some young, hungry bureaucrat would love to sink his or her teeth into a nice fraud conviction. Just make sure you're right before you get heavy.

Repairs

From time to time you'll get a kit or a finished product that either doesn't work or doesn't come up to spec. The problem may be at your end or the company's; you won't know for sure until they've looked at it. So don't assume the design is lousy, or that the company is putting out a piece of garbage: You could have a cold solder joint, or the company's supplier may have slipped them a bad component, or anything. When dealing with a repair, first check the unit over thoroughly yourself, preferably on two different days and with a friend who also is familiar with electronics. Sometimes unfamiliarity with a unit prevents getting good results; how can you set up a unit to do something when you aren't quite sure what it's supposed to do? I run into this problem sometimes with the musical modifiers I design; people don't know what it's supposed to sound like, so if there's a bum IC and a distorted sound, they might assume the distortion is part of the effect. Sometimes a phone call to the tech person at the company is all that's needed; sometimes a letter, carefully describing the problem, can save you having to return the unit. So, always write the company before returning something. This isn't just to find out if others have had the same problem – sometimes a company will move and your package can end up in post office limbo; sometimes a company has a separate repair facility, and you could save time by sending your problem child directly to the repair facility. Also, a prior notification alerts the company to watch for your unit.

No company gets rich on repairs; one company I know has yet to charge for any repairs it has done, even those which were the customer's fault. They do enough business, and have a low enough rate of returns, that they can afford to do this. But not all companies can be that generous, especially when asked to repair a problem they didn't cause (bad wiring or soldering, for example). In many of these cases, if the builder, upon receiving the kit, had simply looked at it, recognized it as being beyond his ability, and returned it unbuilt, he could have gotten a full refund. But to botch a kit and then expect the poor company to make good – for free – is too much, and people can expect to pay for their mistakes. This isn't real good for their pride, maybe, but I have seen some genius computer programmers do lousy soldering jobs. If you're new to kits, start with something simple, then move on to the heavy stuff. Until then, buy your units assembled if you have doubts about your abilities. In many cases, the manufactured units also have more extensive warranties.

When you return the kit, pack it well. You don't want things to go from bad to worse in transit. Also, get a self-stick label and put your name and address on the piece of equipment itself (you won't regret it). Include in the package a thorough description of the problem, along with copies of any pertinent letters (don't say "this is a kludge"; be specific). You can save a repair technician lots of time by relating your experiences with the unit. In your letter, you might also mention that if repair costs are more than a certain amount (whatever you are willing to spend and feel is reasonable), to please notify you by post card. This way, if there is some really bad problem, you won't get any surprises. If it's any consolation, the companies I have seen are conscientious about repairs. Just as word of mouth is the best advertising, a non-working product is the worst. Plus, a company can gain respect by handling repairs in a prompt and intelligent fashion.

Summing Up

So far we've talked about all the things that can go wrong, and the nightmares that a mail-order operator or customer may confront. Lest you get the wrong idea, just as the majority of companies are ethical, so are the customers. Most are courteous, patient, decent people who trust the companies and have that trust confirmed by a company that acts likewise. Businesses are truly grateful for their customers, and frequently recognize the names of repeat customers. The point is that even the biggest companies are run by people; you're not dealing with nameless automatons at the other end. So you should know that your patronage is valued, and enjoyed, and they want to keep you as a customer. In this respect, you owe them one favor. If a company does something that leaves you feeling let down – whether it's a part that doesn't meet spec, a delivery commitment that isn't kept, or a kit that doesn't seem to work right – let the company know. Don't just write it off; you may be writing off something whose only problem is a hairline short on a circuit board. If it is a problem at the company's end (like a design flaw that only shows up under certain conditions), they *need* to know about it. Otherwise, they can send out hundreds of the things before someone says something and the error gets corrected. Companies do extensive prototyping, but even then, you can't cover all circumstances of operation. So if you're disappointed, speak up! But remember, you're writing to someone with feelings. Don't just say something is a piece of garbage; be specific, constructive, and objective. You will be doing everybody a favor . . . it's feedback for the company, an elimination of the problem for future buyers, and you've made a contribution.

I hope that all the preceding will help you get the most out of mail-order companies. I buy almost all my parts that way. I've had some bummers, but none that the company wasn't willing to make good (usually with profuse apologies). Treat them like human beings, and you'll be treated likewise. Help them a little bit by following these tips, and you'll simultaneously keep the costs down for yourself and fellow mad scientists . . . and score quite a few bargains in the process. ■

Social Events

from page 167

1302 West Main St., Owosso MI 18867.

CHENEY WA
JULY 16-17

The Spokane Amateur Radio Council (SARC) will hold its third annual hamfest July 16 and 17, 1977 in the Pence Union Building at Eastern State College, Cheney, Washington, about 15 miles west of Spokane. Pre-registration is $9.50, the same as last year, which includes the banquet on campus and many prizes. Numerous seminars, flea market and activities for YLs, XYLs and MYLs. Make pre-reg checks payable to SARC and mail to Jim Johnson WA7BWO, Drawer "A", Cheney WA 99004.

ALLENTOWN PA
JULY 17

The Tri-Club Hamfest will be held July 17, 1977 from 8 am to 5 pm at the Allentown Police Academy Pistol Range in Scenic Lehigh Parkway South at Allentown PA. Admission is $1.00 to all including sellers. Children are free. Talk-in on .34-.94 and .52.

EAST MCKEESPORT PA
JULY 17

The Two Rivers Amateur Radio Club will hold its 13th Annual Hamfest on Sunday, July 17, 1977 at the Green Valley Fire Department fairgrounds off U.S. Route 30 near East McKeesport. With the expanded parking facilities and the addition of a large flea market area, this event has become one of the largest of its kind in Western Pennsylvania. For more info contact John Roberts WA3SOZ, Secretary, Two Rivers Amateur Radio Club, McKeesport PA 15132.

BOWLING GREEN OH
JULY 17

The Wood County ARC Ham-A-Rama is Sunday, July 17, 1977 from 8:00 am to 5:00 pm, at the County Fairgrounds in Bowling Green, Ohio (about 25 miles south of Toledo). Free parking and admission. Donation $1.50 advance, $2.00 at the door. Tables $2.00. Talk-in on 146.52. Refreshments available. For further info write WCARC, 7929 Rudolph Road, Rudolph, OH 43462.

EUGENE OR
JULY 23-24

The Annual Lane County Ham Fair will be held on July 23-24, 1977 at the Lane County Fairgrounds in Eugene, Oregon. Registration donation will be $2.00. CW contest – fox hunts on 2 meters – swap and shop – commercial displays – prizes – YL craft table. A Saturday banquet at $4 per plate with musical entertainment from 7 pm until midnight. Free parking for RVs with limited free hookups. Advance registration contact Earl E. Hemenway K7KVV, 2366 Madison St., Eugene OR 97405.

SLATER MO
JULY 24

Indian Foothills Amateur Radio Club will hold their Hamfest and Communication Show on July 24, 1977 in Slater, Missouri at the city park. Activities include flea market for OM, flea market for XYL, equipment you wish to display, old – new, prize for best home built, KØRWG and wife musical entertainment, kiddie pool, swimming pool, and tennis courts. Talk-in 94, 52, 28-88, 3963 kHz. For information and registration: R. D. Beilsmith WOKNF, Box 74, Slater MO 65349, phone: (816) 529-2173.

NEENAH WI
JULY 24

The 3-F's A.R.C. Northeast Wisconsin Swapfest will be held Sunday, July 24, 1977 in Neenah, Wisconsin, 0900-1500. This annual event features inside tables, food and refreshments, bar and easy access from U.S. Highway 41. (Take Wisconsin Highway 114 exit east, then take first left to the Neenah Labor Temple at 157 South Green Bay Road.) Dealers will be there, an auction at the end of the day has traditionally offered super deals, and there's a special $3 rate for families. Talk-in on .94/.94. Admission $1.50, tables $2. Send advance reservations to 3-F's, Box 1032, Neenah, Wisconsin 54956.

FLAGSTAFF AZ
JULY 29-31

The Ft. Tuthill Hamfest will be held July 29-31, 1977. Ft. Tuthill is the historical name given to the Coconino County Fairgrounds located on Rt. 89A south of Flagstaff AZ. Hamfest activities include a transmitter hunt on 2 meters, exhibits and demonstrations on many facets of amateur radio. Technical sessions, special contests, and many other interesting activities. Talk-in frequencies will be 146.22/82, 146.52, 3.910 MHz. For more information write Ft. Tuthill Hamfest, PO Box 11642, Phoenix AZ 85061.

OLIVER BC
JULY 30-31

The Okanagan International Hamfest will be held July 30 and 31, 1977 at Gallagher Lake, 8 miles north of Oliver, B.C. Family fun, contests, flea market, and gabfest. KOA campsites available. No inflation prices. Prizes galore. Talk-in 34/94. For more information contact Phil Wilkinson VE7ALV, Naramata, B.C.

FARMINGTON NM
JULY 30-31

The Totah Amateur Radio Club, Inc., will hold its club field day on July 30 and 31, 1977, at the Four Corners National Monument (New Mexico, Arizona, Utah and Colorado). Mode: SSB and CW, bands – 15, 20 and 40. Club station call K5WXI.

NORTH MANKATO MN
JULY 31

The Mankato Area Radio Club will hold its annual picnic, swapfest and auction on July 31, 1977, between 10 am and 4 pm at Spring Lake Park in North Mankato MN. Talk-in 3.93, 146.94 and 146.25/85 MHz. Liquid refreshments will be available; bring your own dinner. For further details write the Mankato Area Radio Club, Box 1961, North Mankato MN 56001 or call Allen Windhorn at (507) 931-1349.

MACS INN ID
AUG 5-7

The 45th Annual WIMU (Wyoming, Idaho, Montana and Utah) Hamfeast is scheduled to be held at Macs Inn, Idaho, just south of West Yellowstone about 25 miles. This is one of the Rocky Mountain Northwest's largest hamfeasts and we would like to invite you to attend, and at the same time enjoy a tour through Yellowstone National Park. Advance registration is $6 (before July 1st). $7 at the Hamfeast. Please send all pre-registrations to WIMU Hamfeast, PO Box 30756, Billings, Montana 59107, c/o Ronald Conley, General Chairman, WIMU Hamfeast.

NEWBURGH NY
AUG 6

The Mt. Beacon Amateur Radio Club will hold their 4th Annual Hamfest on Saturday, August 6th, 9 am to 5 pm, at Stewart Field, Newburgh NY, inside hangar. Flea market and auction. Talk-in on 37/97 and 16/76. Rain or shine. Plenty of free parking. Admission $1, Tailgating $1, under 12 free.

JACKSONVILLE FL
AUG 6-7

The Bold City Hamfest sponsored by the Jacksonville Range Association will be held at the Jacksonville Beach Auditorium August 6-7. Vacation at our Hamfest – Florida's Friendliest. Visit our special "Solar" and "QRPp" forums. Send request for information and tables to Hamfest Coordinator, Jacksonville Range Association, PO Box 10623, Jacksonville FL 32207. For motel reservations call Ramada Inn toll free (800) 228-2828.

OKLAHOMA CITY OK
AUG 6-7

The 1977 Oklahoma Ham-Holiday will be held August 6 and 7, 1977 at the Southgate Inn Best Western, 5245 South Interstate 35, Oklahoma City, (405) 672-5561. Pre-registration $3.00, at the door $4.00.

FORT WAYNE IN
AUG 7

The Orignal FM Hamfest will be held Sunday, August 7, 1977, rain or shine, at the Allen County Police Reserve Center, 3022 Easterday Road, Fort Wayne, Indiana. 5400 square feet of air conditioned exhibit area, hot food and refreshments and prizes. Sponsored by Fort Wayne Repeater Association, Inc. Advanced registration $1.50 – call in to WA9EAU on 146.16/146.76, WR9ADI 146.52 or 52.525 MHz. Tickets at door $2.00. Taped route information available on 146.91 MHz. For more information and advance tickets please write: Fort Wayne Repeater Association, Inc., PO Box 6022, Fort Wayne IN 46806.

ANGOLA IN
AUG 7

The Steuben County Radio Amateurs presents the 19th Annual F.M. Picnic and Hamfest to be held on Sunday, August 7, 1977, at the Steuben County 4-H Park, approximately 2 mi. west and 2 mi. north of Angola, Indiana. Hamfest includes picnic-style B.B.Q. chicken and refreshments, inside tables for exhibitors and vendors, overnight camping permitted in park for those desiring to arrive Saturday, movies Saturday night, as usual. Tickets $1.00 by donation, advance registration not necessary. Talk-in frequencies 52.525, 146.52, 223.5, 446.0.

CANTON OH
AUGUST 7

The Canton, Ohio, Hall of Fame Hamfest (an official ARRL hamfest) will be held at the Stark County Fairgrounds on Sunday, August 7, 1977. Hamfest includes ARRL, Amateur Electronic Supply, Ken-Mar Industries, Omar Electronics, flea market, YL activities including games and drawings. Admission $3 at gate, $2.50 advanced. Under 13 years of age free. For advanced reservations contact: Butch Lebold WA8SHP, Box 3, Sandyville OH 44671. Advanced deadline July 30, 1977. For directions and information call: W8ZX on 146.19/79 (WR8ADE) or W8AL on 146.52/52. Mobile check-in prize!

PITTSBURGH PA
AUG 7

The 40th Annual Hamfest of the South Hills Brass Pounders and Modulators will be held on August 7, 1977 from noon until dusk at St. Clair Beach, Upper St. Clair Township, 5 miles south of Mt. Lebanon, on Rte 19. Swap and shop, picnic space and swimming for the family. Mobile check-in on 29.0 and 146.52. Information and pre-registration at $1.50 per ticket ($2 at door) from Rich Eckenrode, 1410 Bellaire Pl., Pittsburgh PA 15226. Vendors must register.

LEVELLAND TX
AUG 7

The 12th annual West Texas Emergency Net Picnic and Swapfest will be held in the city park, Levelland, Texas on Sunday, August 7. Bring your own picnic basket. Registration begins at 8 am. Lunch at 12:30. Swapping all day. Tables are provided. This family event is jointly sponsored by the Hockley County Amateur Radio Club and the West Texas Emergency Net. Mobile talk-in frequency is on 2 meters only, on 28/88, the Levelland Repeater (WR5AFX). Prizes will be given this year and a $2 donation will

be appreciated, but is not required for registration.

WASHINGTON MO
AUG 7

The Zero-Beaters ARC will hold their annual Hamfest on Sunday, August 7, 1977 at Washington, Missouri city park. Free parking, bingo, and many prizes. No admission fee or fee for parking in the trader's row. For info or tickets contact Marvin Holdmeyer WBØVPF, or Zero-Beaters ARC WAØFYA, Box 24, Dutzow MO 63342.

AMARILLO TX
AUG 12-14

The Panhandle Amateur Radio Club of Amarillo, Texas, is sponsoring the 1977 Edition of the Golden Spread Hamfest at the Holiday Inn West, Amarillo, Texas, August 12, 13 and 14. A grand prize and pre-registration prize worth over $800 will be given away. Activities include six big tech and info sessions, commercial exhibitors, flea market, free bingo for all, two hospitality hours, live entertainment, special activities for the ladies, and demonstrations. Pre-registration $3, at the door $4. Write Golden Spread Hamfest, PO Box 10221, Amarillo, Texas 79106 for pre-registration packet.

POLSON MT
AUG 13

Western Montana amateurs will sponsor an annual Mini-Hamfest on Flathead Lake, near Polson, Montana, on August 13, 1977.

CHARLOTTE VT
AUG 13-14

Burlington A.R.C. International Field Day will be held on August 13 and 14, 1977, at Charlotte, Vermont. Flea market both days 7 am Saturday to 5 pm Sunday. $3.00 early bird registration. $3.50 at door — write P.O. Box 312, Burlington, Vermont. Talk-in .01-.61.

PLAIN CITY OH
AUG 14

Union County Amateur Radio Club proudly presents Hamfest 77 to be held on Sunday, August 14, 1977 at Plain City Fairground near Columbus OH on St. Rt. 42, 4 miles south of 33. Hamfest includes large flea market, indoor tables for dealers, food available, free parking, and free overnight camping. Admission $1.50 advance, $2.00 at gate. Talk-in on 146.16/76. Check in (for prize) on 146.52. For more information write: Union County Amateur Radio Club, 13613 U.S. 36, Marysville OH 43040.

FORT WASHINGTON PA
AUG 14

The Mt. Airy VHF Radio Club (the Packrats) is holding its annual family picnic in the Flourtown Area of the Fort Washington State Park on Sunday, August 14, 1977 (rain date August 21). Talk-in W3CCX/3 on 52.525, 146.52, and 222.98/224.58 MHz.

BRISTOL TN-VA
AUG 13-14

The Bristol Amateur Radio Club, Inc., will hold the Bristol Hamfest August 13-14 at the Beacon Drive-In Theatre on Blountville Hwy., 9 am to 5 pm, Saturday, 9 am to 3 pm Sunday. Tickets $1, flea market space $2. Talk-in on 01-61, 28-88 and 3980. Contact Bristol Amateur Radio Club, Paul E. Booher WA4KAS, 1221 Jonesboro Road, Bristol VA 24201.

DESOTA IL
AUG 22

The SARS Hamfest will be held on August 22, 1977, in Desoto, Illinois. Program includes prizes, food, auction. No charge for flea merchants. For more information write Nick Koeningstein, 2009 Gray Dr., Carbondale IL 62901.

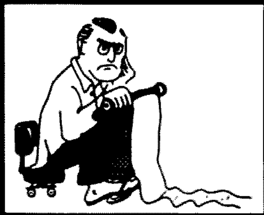
73 AMATEUR RADIO



NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

ARE YOU MISSING SOME GOOD ARTICLES IN KILOBAUD? YES!

Our policy is to make sure that articles are not reprinted between *73* and *Kilobaud* . . . and this means that you are missing a lot of very important material if you are not getting *both* magazines.

The articles in *Kilobaud* cover a wide range of topics, centered on the new microprocessor chips . . . articles on wire-wrapping, how memory works, the new printers, handling ICs, surplus keyboards, video terminals, video generators, and a lot of stuff on the various microcomputers and programs for them . . . a whole lot.

Most of this material will be published just once, so you'll need your back issues of *Kilobaud* to use as a library for reference . . . on business programs, games, operating systems, interconnections of popular boards, etc.

You'd best send in your subscription now . . . before this new scene gets too far away from you. It's going to be big . . . and fun . . . and there is more opportunity here than in anything we've seen in the past.

Send in your subscription to *Kilobaud* and find out why it is the most popular small computer magazine out. It's just as packed with good articles as *73* . . . and you already have the background to understand them.

OPENINGS AT 73

The staff at *73* is at an all-time high . . . and still more are needed to pursue the expanding magazine, book, and computer aspects of the business. Help is needed in the form of a dyed-in-the-wool amateur with writing and editing experience, to help with the rapidly growing book department. Help is needed in drafting. We need someone to work at *73* and draft the schematics for the magazine. Computer programmers and technicians are needed to help with the development and production of business and educational programs for microcomputers.

Oddly enough, *Kilobaud Magazine* may surpass *73* in revenues within its first year of publication, and the sale of computer programs is expected to soon dwarf both magazines in sales.

Our first big exposition, COMPUTERMANIA™, will be held in Boston in late August, and is the first of many such expositions we'll be running. This show is budgeted at $350,000, so it is a big undertaking. Further shows are being planned for San Francisco and other cities, using the team which will be putting on COMPUTERMANIA. Not bad for a tiny group of people in New Hampshire who are having the time of their lives.

Nishi, Sherry, and Wayne in Los Angeles.

CODE LEARNING SYSTEMS STUDIED

A recently released study from the University of Southern Illinois showed the results of a series of code learning tests. The conclusions to be drawn from these tests were inescapable.

This was essentially a test of the *73* system of learning the code vs. the system used by most other code courses (such as those from the ARRL). The main difference is that the *73* system starts beginners out with the sound patterns of code sent at 13 words per minute, while the others start out with the individual characters sent at a very low speed and change the sound patterns as they speed up.

The result, as has been noted in *73* before, is that the *73* code tapes do not have the pronounced learning plateau to be surmounted that other tapes do. Thus the *73* tapes require substantially less time for mastering the code.

The faster learning with the *73* code tapes results in a much higher percentage of Novices being licensed, and far fewer dropouts in the Novice courses run by clubs. Clubs running Novice or Tech (or General, for that matter) programs should make note of this and use the *73* Morse code tapes.

I/O MAGAZINE

The first hobby computer magazine in Japan got started last November. The editor and publisher is a very active ham and computer fanatic by the name of Nishi. Where did the magazine's name come from? From the I/O section of *73* — which he's been reading for years.

Nishi came up to visit *73* HQ last winter — a most interesting and entertaining chap. It is a little unsettling to see what Nishi has done so far . . . and he's only 21 years old! He's been into computerized music for several years

Looking West

Bill Pasternak WA6ITF
24854-C Newhall Ave.
Newhall CA 91321

For eleven years it was known as the Lockheed Burbank Hamfest, a nice little get-together sponsored by the Lockheed Amateur Radio Club/ Lockheed Employees' Recreation Club. I have always enjoyed it, as it gave me a chance to eyeball many of my peers without having to travel a few thousand miles to do so. Each year, though, I noted that it drew more and more attendees and a greater number of exhibitors — in general, it showed a definite growth pattern.

This year, renamed the "12th Annual Los Angeles Amateur Radio Convention" by its sponsors, the old Burbank Hamfest reached the status of a "great one" in your reporter's opinion. Along with Dayton and Atlanta, it truly fulfills the goal it has set for itself: to educate and entertain. Like Dayton and Atlanta, the L.A. convention features exhibits both of manufacturers and of the special interest variety, such as one depicting an early amateur station. Also like both Dayton and Atlanta (and unlike SAROC), there are ongoing symposia on just about any topic that you could dream of. At this convention, the sponsoring organization makes sure that everyone in attendance leaves with a feeling of satisfaction. Moreover, if someone happens to win a prize valued at more than $30, he need not be present to claim it. All prizes whose value exceeds that figure are shipped to the winner. That's a comforting thought when the grand prize happens to be an FT-101EI

You might get the idea that I enjoyed my visit to "beautiful downtown Burbank." It's really more than that. I know a lot of the people involved in putting on this annual show. I have had the opportunity to sit with them and speak with them, and I know full well the measure of total devotion that goes into making each year's Los Angeles Amateur Radio Convention a greater success than the last. It's a convention put on by hams for hams, and the level of pride is evident. Whether you are an avid DXer, an OSCAR enthusiast, or are interested in finding out about the latest equipment available to locate the turkey who's jamming your favorite repeater, you will find something of interest in Burbank. I predict that next year will be even better.

For information on next year's "13th Annual Los Angeles Amateur Radio Convention," write to the Lockheed Amateur Radio Club, 2814 Empire Avenue, Burbank CA 91504.

Who said 220 never has band openings! As I sat here writing this, I received a call via WR6AWQ from Warren Andreasen N6WA/WA6JMM, who related the following: The other evening, while taking advantage of the well-known Southern California "inversion," Warren was in QSO with Lon Albright W6SLF on 223.5 MHz. Lon happens to be located in San Diego, which makes for a 90 mile or so path (which in itself is not bad, especially since Warren's abode is in the center of the San Fernando Valley). Shortly after signing with Lon, Warren noted another conversation on 223.5. It was in Spanish, and each transmission ended with the telltale "crash" of some form of relay device (such as a repeater). Since he neither speaks nor understands the Spanish language, Warren could only make a supposition as to what he was hearing, based upon his beam heading and his working knowledge of 220 activity. His conclusion was that he was hearing the La Paz, Mexico, police department, which operates on 223.5 — and also happens to be about 1,000 miles away. If such was the case, then N6WA/WA6JMM probably holds the unofficial 220 MHz SWL DX record, thanks to a hand from Mother Nature.

Month after month I keep forgetting to do something, so before I forget again, here goes. Question: What's an FM-144DX? Answer: It's a mistaken nomenclature for what is really an FM-28, manufactured and distributed by Clegg Communications. The real question, still unanswered, is how I came to make the mistake in the first place. To date I do not know. My notebook from SAROC is chockfull of goodie information gathered, and includes the notation "New Clegg 2 meter radio — FM-144DX — refer pictures two and three roll B." However, after submitting the article for publication, I happened to call Ed Clegg to set up an interview appointment for an article soon to appear in this magazine, and he informed me that my model designation is not exactly the correct one. Even funnier, since the article had already appeared in print, he was receiving inquiries as to what an FM-144DX was. To compound matters, I mentioned the whole thing to Bill Orenstein KH6IAF (who happened to spend a lot of time playing with the radio at SAROC) and he confirmed again what Ed had already told me on the telephone.

Three weeks later, along with Larry Levy WA2INM, I was in Ed's office holding in my hand the very same radio that I had played with at SAROC — clearly it reads FM-28. How and where I ever came up with "FM-144DX," I will never know. I am going to "cop out" on this one and blame it on too much Las Vegas night life or something like that. However, those of you who already own one of these beauties know that I was correct on two points: It is a radio that does everything the advertisement promises, and it's available at a price most any ham can afford. It also happens to be backed by one of the finest and most reputable manufacturers in the amateur radio field today: Ed Clegg W3LOY. That in itself means a heck of a lot!

Many of you write to ask why I do not spend time discussing all the rulemaking proposals flowing forth from the FCC in Washington. It's simply a matter of publication lead time. What you are reading today was written at least sixty days ago, and any discussion of pending legislation written now would be a moot point by the time you read it. However, here is a brief synopsis of the points I covered in my official replies to a few of the dockets and RMs.

On repeater/remote deregulation, I felt as follows: (A) The Commission must realize that a specific difference exists between the concepts governing a repeater and those governing a remote base. While the hardware might be similar, the methods in which they function are totally dissimilar and the purpose and/or objective of each is different. (B) Remote bases must be considered as a separate entity, and regulations governing such operation must be separated from those governing repeaters — to give the remote owner the freedom necessary to experiment and thereby advance the state of the art. (C) While repeaters are an important entity, they are but one aspect of VHF/UHF operation. Therefore, I favor retention of repeater sub-bands on certain of our bands to protect non-relay format interests that share the spectrum from encroachment by relay format communication. However, on ten and six meters I favor total deletion of sub-bands, to stimulate activity in that spectrum and to relieve the overcrowded conditions on two and in

Burbank's not as big as Dayton, but it has a good flea market nonetheless.

Is it the 1920s? No— it's W6HS exhibiting an amateur station of that era at the 12th Annual Los Angeles Amateur Radio Convention.

places on 220 and 450. In regard to ten meters, I requested that the Commission act to give Technician class licensees radiotelephone privileges for that band (specifically, narrowband FM, again to help stimulate growth on ten and as a method of preventing encroachment by the "HF" – read that as unlicensed CB – crowd). Sub-bands do provide a significant value on two, 220, and 450, where both relay and non-relay communication share significant amounts of spectrum, and with slight expansion to both two and 450, I favor retention of sub-bands there. (D) I favor deletion of the need for specialized auxiliary link, control link, etc., licenses; I agree with the concept of one license with most privileges contained therein. However, I do favor retention of the specialized repeater license (along with its specific "WR" designation). Having the blanket right to erect and operate a repeater inherent in every amateur license could, and probably would, lead to a multitude of unsanctioned and uncoordinated repeaters, and would thereby lead to an overall degradation of the amateur service. (E) I requested that all deregulation along these lines be instituted on a specific time schedule over a period of two years, with the most pressing problem, that of remote base deregulation, taken care of immediately. (F) Amateurs could prove their ability to administer their own affairs through the formation of a National Voluntary Band Planning Council, made up of elected officials representing each area, mode, and special interest, which would develop lines of communication to the FCC for the purpose of providing feedback to the Commission as to how well deregulation is progressing. Such a council would, in effect, replace FCC regulation with voluntary self-regulation.

In a nutshell, that's a brief synopsis on repeater/remote deregulation. If this were 1969 or 1970, I probably would be looking at this a lot differently. However, this is 1977 – there are over 3,000 systems on the air and many places such as L.A. have plumb run out of room on two and 220. We now face a threat to our spectrum from those who flaunt the law and are slowly inching their way toward 10 meters. If we are to survive and prosper, we must "get it all together" – get off our individual ego trips and make deregulation work toward our own advantage on a collective basis.

It would be nice to say "take all the rules away today," but in reality any society without some form of governmental structure is sure to crumble. History more than proves this out. To many of us, amateur radio is more than just a hobby – it's a dedication in our daily lives. While some of the views I expressed in my reply comments on this matter may not be popular, I believe that they make sense in that they systematically lead to a transfer of power from governmental regulation to self-regulation, and provide some semblance of protection for the sanctity of our spectrum.

De WA3ETD

John Molnar WA3ETD
Executive Editor

CONTEST RESULTS

The results are official! The "*73* Call For Papers" competition ended on May 15 with many entries. You may recall that the intent of the writing contest was to discuss one of the many facets of ham radio in an article appealing to the beginning enthusiast. The articles submitted encompassed subjects ranging from contest operating to the conversion of old receivers. The winning article is by Richard R. Parry. His effort, "So You Want To Get Into RTTY," explains radioteletype in concise, easy to understand terms, and is loaded with pictures and diagrams. Richard's article will appear in the September issue of *73*, an issue devoted to RTTY. Look for it. Congratulations, Richard, and thank you for the other articles, authors! They will be considered for publication and processed normally.

Speaking of special issues – keep your eyes on *73* for the next few months. As you can see, the August issue features antennas and related subjects. Summer is the time to build antenna systems. Hopefully one of the feature articles will provide the stimulus to build the system you've been putting off "until next weekend." Once the antenna farm is complete, you will need some gear for the shack; why not try a new mode? More and more hams are getting into RTTY – give it a try! The September issue will feature RTTY, and some super articles are on tap. Everything from message generators to computer-controlled TUs will be covered. No one remotely interested in RTTY will want to miss this issue! November is OSCAR 8 (AOD) time; that means time for another *73* OSCAR special issue. Our last satellite special (July '75) was a sellout – don't miss this one! About your subscription – don't let it expire now, not with three blockbuster specials coming. Send in the renewal card, and make sure your friends do the same – if you lend one of the special issues, the chances of never seeing it again are good!

CB TO 10

The response to the continuing series of CB to amateur conversions has been fantastic. We presented several "band plans" in hopes that reader response would allow us to promote one of them. Check Ray Barnum's plan (June '77) and Wilder's (May '77) and let us know which you favor. Several additional conversions are on the press. Some readers have indicated a problem with information provided in Bob Wilder's article, concerning the Cobra conversion. It appears that a simple crystal switch will not effect the desired change. Refer to "Letters" for information by WB3CJI concerning the Cobra modification. Watch for additional CB to amateur band articles.

TIPS FOR AUTHORS

I have several suggestions to pass along to present and future *73* authors. Most of the submitted manuscripts look good; however, a few problems prevail. Please type your effort! After reading several dozen letters, product releases, articles, and reviews, a handwritten manuscript can be murder. Most are sent back for typing. Editor's eyesight aside, there are practical reasons for typing. Our typesetter must produce magazine type directly from your manuscript – why make her guess at the handwriting, especially in a technical article?

Photographs: Good pictures make a fine article better and increase the size of your check. Please do not send Polaroids or Instamatic shots. The photos you send are converted directly into magazine pictures (halftones); thus the original quality is important. We would like 5 x 7 black and white pictures if possible. Negatives are not required – keep 'em in your file.

Please write your name, address, and call on each manuscript page and photo. This allows us to keep track of your article.

TIPS FOR READERS

Several authors have complained about receiving large volumes of mail concerning their *73* article. This is fine and to be expected, but when requests for information come without an SASE, it's a bit much! Imagine receiving fifty questions about an article and having to provide fifty stamps and envelopes, as well as the time required to answer queries. The SASE is a required courtesy when corresponding with authors. Give them a break! The same applies when writing *73* for information. We are not really equipped to answer technical correspondence – that's what "Ham Help" is for; however, we do our best when possible. SASE is required!

NEW TRENDS – 10 GHZ BECOMES ACTIVE

My experiments with the Gunnplexers by Microwave Associates are continuing. The microwave front end requires a 30 MHz i-f and FM detector to function, as well as power and control voltage. Modulation is applied to the Gunn oscillator by coupling audio to a varactor diode which is an integral part of the transceiver. A number of schemes can be used for the 30 MHz i-f. My system consists of VHF Engineering receiver modules and a home brew 30 MHz to 10.7 MHz converter. The VHF modules are a natural for the application, as a complete receiver can be custom-tailored using the receiver strips. I will describe my system in detail in a month or two. If you have done any experimenting with microwaves or Gunnplexers, let me know. Many *73* readers are interested in UHF and microwave experimentation; if you're already into something, pass along your knowledge to the beginners!

Concerning UHF: I made a trek up Pack Monadnock Sunday, loaded with gear for 432-450. The rigs consisted of the Icom 30A FM transceiver, KLM Echo 70 SSB combo, and the VHF Engineering BLE 10/80 power amp. The UHF antenna was the KLM 27 element log, which allowed operation from 432 to 446. The DX results were a bit discouraging. I guess not many people sit around on Sunday afternoon monitoring 446.0 simplex, as only a few stations were worked. I did discover a large crop of repeaters up there, and activity was light. If anyone needs New Hampshire on UHF, drop me a line and we can set up a sked, either on 446.0 or 446.5 FM, or on SSB down below. I have the capability to stack another 27 elements, and should be able to work into New York if someone is on the other end. If you have not tried UHF, you're missing something – especially if the requirement for dependable line-of-sight communication or control is present. Authors take note – your UHF articles will be well received. Keep the beginner in mind when you start writing about UHF and microwaves! Have fun and keep us posted!

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Last month I described how letters, figures, and special machine functions are encoded for dc transmission. Recalling that all characters are represented as five pulses, this month we will investigate techniques for sending encoded information by radio.

A CW transmitter can be keyed directly by the TTY pulses. The result is called "ON-OFF" keyed RTTY. Fig. 1 illustrates this technique. Subsequent figures are also grouped here for comparison. ON-OFF keying was, in fact, the earliest method used to transmit TTY over the air. Advantages are related to simplicity in transmitting: Merely hook the TTY to the key jack! Receiving is also easy, and reception techniques for all modes discussed will be covered in a subsequent column. Disadvantages relate primarily to interference susceptibility and fading. A nearby CW signal can wipe out an ON-OFF TTY station, and fading can remove whole letters.

A better way to send TTY is by presenting a constant signal for the MARK state, and changing it in some way for representation of the TTY signal. Changes may be introduced in amplitude, frequency, or by a superimposed modulating waveform. Direct amplitude modulation with the TTY approximates ON-OFF keying, with all its attendant flaws. Some fancy forms will be discussed at the end of this column, but the two most used ham methods are FSK and AFSK.

In FSK, frequency shift keying, a carrier is shifted in frequency to correspond to MARK and SPACE. Fig. 2 diagrams this nicely. This system, as are all to follow, is a redundant system. That is, information is obtainable by looking at either MARK or SPACE, even in the absence of either one. (Remember that in ON-OFF keying, if you lose the SPACE, you have a steady MARK, and if you lose the MARK, you have nothing.) Transmission of FSK is accomplished by shifting the transmitter vfo in step with the TTY, and reception, by decoding either or both the MARK and SPACE. Done properly, this system is very immune from interference, and, since fading normally affects only one of the MARK or SPACE frequencies at a time, proper use of the built-in redundancy makes fading no problem either. The frequency shift involved may be anything from kilohertz to fractions of a Hertz, which might be more properly called "phase shift." In amateur circles, "standard" shifts are 850 Hz (wide, old) and 170 Hz (narrow, new).

Unfortunately, FSK presumes very stable transmitters and receivers. The level of shift is less than one kHz, and drift in the vfo of any significant degree would be intolerable. VHF transmitters, especially early ones, could not maintain this degree of stability. Use of an audio tone, shifted in frequency in a manner similar to FSK, became the standard on VHF links. Take a look at Fig. 3. This AFSK is more useful than it appears at first glance, and some of its uses will be covered in future columns.

Finally, as promised, some erotica — I mean, exotica! What if I send a pulse during each 22 ms "window" representing a TTY bit? By changing the pulse's amplitude or position within the window, I could encode MARK and SPACE with a decodable system. Fig. 4 shows what I mean. Such Pulse Amplitude Modulation (PAM) or Pulse Position Modulation (PPM) is not used much in the amateur service, but it is neat, huh?

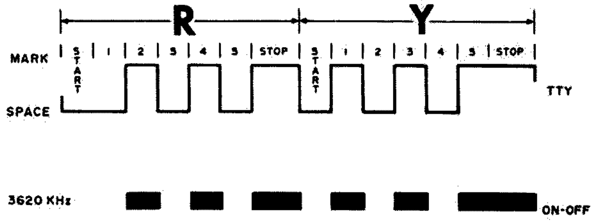

Fig. 1.

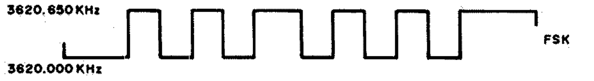

Fig. 2.

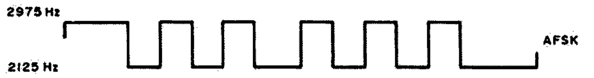

Fig. 3.

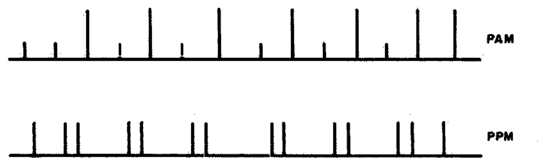

Fig. 4.

Next month we will discuss the hardware necessary to receive a RTTY signal. Details concerning the Model 15 printer will be provided, as that machine is widely available at reasonable prices. If you are interested in getting started in RTTY, it would not be a bad idea to shop around for a usable Model 15. The machines are available at flea markets, as well as through commercial sources. Details will be provided in future editions of the RTTY Loop.

NEW ENGLAND RTTY REPEATER

Best of luck with "RTTY Loop"! I hope it will be a success. You'll be hearing from me from time to time as I am an avid RTTYer. I'm also net control for a local 2 meter TTY net. We meet each Wednesday at 9 pm on 147.69/.09 (WR1ABN) at 60 speed, 850 Hz shift. We exchange pictures, and a couple of the boys have microprocessors which we play with on the air. Perhaps you could mention us in your column and help "spread the word."

Dick Peters WA1PWF
27 Lafayette Lane
Norfolk MA 02056

If your group is involved in a unique RTTY application, let 73 know. Keep your letter short. Each month, space allowing, we will publish as many letters as possible. — J.M.

Ham Help

To Whom It May Concern: HELP!!

I have been trying to get into SWLing for the past year now and have been frustrated at every turn. I have studied the equipment catalogs and such and the prices have taken me aback somewhat. I do not know what equipment can be had that will do a good job and keep within a self-imposed $300.00 budget. Yesterday I picked up your mag (the first one I had ever seen!) and found it helpful. Your article on receivers was outstanding! But alas, where might I find excellent used quality equipment at a good price?

My knowledge of antennas is kaput for the present. The space I have for an antenna is severely limited except for the possibility of a longwire type. I am not familiar with any other type I can use.

Sorry if I have sped a deluge of questions your way, but I'm a babe in the woods not wanting to be taken at every turn and wanting to learn more about this new-found hobby. I am currently limited to a GE 10-bander my wife bought me last year for my birthday and hence my interest was born!

Any and all help will be deeply appreciated.

Robert B. Goltare
4100 N. O'Henry Blvd.
Box 126, Oakwood Forest
Greensboro NC 27405

I am a freshman college student who is majoring in Electrical Engineering and is disenchanted with Citizens Band radio communications. I currently hold only a CB license, but I am independently studying on my own for the Technician license so that I can operate on 2 and 6 meters. I would like to meet, contact, or correspond with amateur radio operators or clubs in my area who can fill me in on local testing procedures, 6 and 2m radio communications (especially repeater operations). I would also like to know if there are any clubs or schools giving Morse code classes.

I also need a schematic for the Heathkit 6m transceiver (HW-29), the original which has only 4 tubes (6AU8, 6AN8, 12AX7, and 6AQ5), not the later type of the same model which has an additional suffix "A", as in HW-29A, which is the only schematic I was able to obtain from the Heathkit Co.

Raymond Tom
1646 West 87th St.
Chicago IL 60620

You sure have a fine magazine there, especially since it gives everyone an equal chance to voice an opinion whether you there at the plant agree or not.

Well, this letter is not meant to mound praise on your magazine, even though it is a very good one, but to ask you if you would please place in ham help that I am looking for alignment info and a schematic to photocopy for a Heathkit AR-3 and a Bendix FM transceiver converted to two meters, model no. MRT-6FB.

Your diversification will keep your magazine on my renewal list. Again, thanks for a very fine magazine.

New Products

THE DENTRON MLA-2500 LINEAR AMPLIFIER

Dentron Radio represents the kind of American success story you often read about. It began just three years ago in a basement workshop, but Dentron today occupies a modern plant with over 60 employees. Dentron products are in use all over the world in applications just as varied as the languages of the customers. The company has made its name on tuners and antennas, not to mention the 160m transverter that Dennis Had K8KXK designed and built in his Ohio basement workshop three years ago.

The company has taken a different approach in developing its product line than most. They've gone from the transverter and matching antenna tuner to a complete line of antennas (fully assembled and ready for installation as they leave the factory), a complete line of tuners, to amplifiers, and, before year's end, to HF transceivers. There has been a refinement process along the way, and with each new product, Dentron has opened another door, another market.

With the introduction of the MLA-2500 amplifier, for example, the company found itself swamped by orders from (among others) the US military (SAC), foreign government and commercial interests, the medical research community (which uses the MLA to produce rf at continuously controlled levels for cancer treatment), the welding industry, researchers probing the separation of iron ore, HF satellite ground linking, and, of course, the amateurs for whom the amplifier was designed in the first place.

Demand for the MLA has far exceeded supply at Dentron dealers across the country, and it is expected that that situation will continue for some months to come. (By the time this issue reaches you, however, availability should be up.) But why do so many people want MLAs? Read on.

The MLA-2500 weighs just over 45 pounds (including full duty built-in power supply), measures only 5 inches high by 14 inches wide (about the same width as the popular Heath SB-200 1200 Watt amplifier) by 14 inches deep. The MLA is surprisingly small in size for an amplifier of its class (2000 Watts in the amateur service, 2000 plus Watts in commercial and military service), and runs as if the 8875 finals were somehow water-cooled, instead of by forced air. It is significant to note that at no time in more than two months of testing did the MLA ever reach more than a "warm" temperature; that is, the MLA actually ran cooler than any other piece of station equipment (exciter, receiver, scopes, and so on). Not even after an afternoon of SSTVing on 20m was the MLA observed to be abnormally warm, and the main comment from visitors to the shack (aside from finding the aesthetics of the amplifier very pleasing) was how surprised they were that the unit ran so coolly. As can be seen in the photograph, nearly all of the system's cooling action is directed towards the tubes and associated output stages, while the power supply, control, and relay boards must rely on circulated air, independent of the forced air system on the 8875s. A dual speed cooling system is used, with automatic override of the slow speed function when tube plate temperatures approach unsafe levels (over 200 degrees C). Even that automatic function can be overridden through a "continuous duty" feature, which locks up the cooling system at maximum. Dentron recommends use of the MLA in a tilted-up position, through the use of a hinged bail between the front feet. A 19 inch rack panel mounting kit is also available.

Another reason for the MLA-2500's quick acceptance and popularity is performance. It takes only 36 Watts of drive to produce a full kW input (or 65 Watts to yield 2 kW PEP for SSB operation) on 160 through 10m. Efficiency, according to checks with

The Dentron MLA-2500 160-10m linear amplifier. The MLA offers modular construction, with a two step forced air cooling system.

an outboard Bird monitor, is outstanding, with over 700 Watts out at 1 kW input, making for 70% efficiency. (Lab tests showed that the MLA's efficiency went up with increased power inputs; e.g., at 1336 Watts dc input, the MLA yielded 1000 Watts output, for an efficiency figure of 74%.) At 1 kW input, then, the MLA is running at less than half its capabilities, thus accounting for its remarkable tendency to run very quietly and coolly for hours, even days, on end. It would be fair to say that the MLA is well suited for contest operations, and our tests certainly prove that to be true.

The power supply is one of the MLA's unique features. Offered standard is a low profile 24½ pound transformer designed especially for the MLA. On rural mains, the MLA produced 2300 V worth of plate voltage. A rear panel cover allows access to line fuses and the transformer primary taps for switching between 234 and 117 V ac service, although 234 V ac 15 A service is recommended for this class of amplifier. An important note here is that the MLA produces extremely high voltages, and must be treated with care. Aside from a direct line for the 234 volt service, sufficient grounding is important, and no attempt should be made to defeat Dentron's circuit breaker system, which cuts all voltage to the unit if the covers are removed. The Operating Manual recommends waiting at least five minutes before getting into the unit for cleaning or adjustment, so that the electrolytic capacitors have fully discharged through their bleeder resistors. As with all the other circuitry in the MLA, the power supply is modularly constructed, allowing for easy removal of the associated boards for service.

Tuning the MLA is made easier because Dentron used twin 3 inch meters, one for output in Watts, the other a multimeter for measuring plate voltage, current, and grid current. Whether the MLA is "in" the line or not, the output meter functions, so it is easy to tune your exciter and antenna tuner for the specified drive and flip the amplifier into the line for final tuning. There is little doubt in tuning the MLA; it's an easy, quick process of tuning and loading up to the desired power input. One cannot forget, however, that the MLA is *designed* to be run far from its maximum limits, not unlike a finely tuned sports car capable of much more than the 55 mile per hour speed limit. Enough said?

To account for the easy tuning of the MLA, one only has to check out the tank circuitry. Dentron tried a number of different designs, including silver-plated copper tubing, but found a teflon covered conductor of 19 silver-plated wires worked the best. Dentron engineers discovered that their design allowed for closer windings, thus improving harmonic suppression, which is rated by the factory at better than 55 dB at full power on all bands. There is also the side benefit of extra protection from the use of teflon. Dentron says tests show that the system is especially good in high humidity or salty environments.

Shipped from the factory, the MLA comes in two cartons – one for the main unit, and a smaller package for the 8875 finals, the delay tube, and plug-in control relay. All four devices are easy to install after removing four top cover screws and the cover itself. If you carefully follow the instructions in the MLA Operating Manual, the 8875s will go in easily, but due to their short, narrow pins, it can get a bit tricky. Best idea is to follow the manual!

All adjustments, wattmeter, ALC, and power transformer taps, are accessible without removing the MLA's covers. All controls are factory aligned, and I did not find it necessary to readjust them. Operating the MLA, in fact, was about as troublefree as possible ... there really wasn't a glitch encountered during our test period.

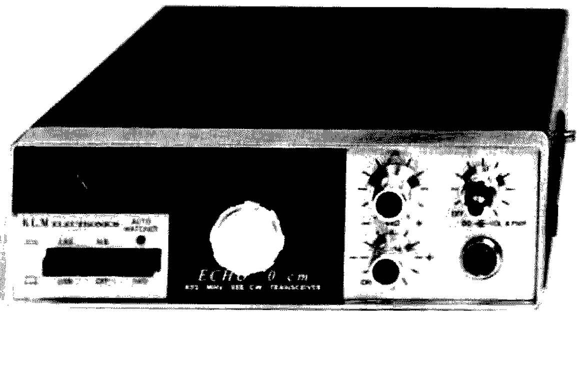
Operating the MLA is very satisfying. One of our editors put it this way: "Using the MLA-2500 in conjunction with my Heath HW-101 was one of the most pleasant experiences I have had in ham radio. It was nice being told over and over again that I had one of the best and strongest signals on the band, be it 40 meters or 15. This was all done with the use of only dipole antennas, so there was little that could be credited with the great signal strength reports except the amplifier. The MLA is also very easy to operate; in fact, it is so easy to use that at first I thought I must be forgetting something. I wasn't, however, because the signal was very definitely there."

My use of the MLA began with the last ARRL DX phone weekend, and its performance left me reeling. Using wire beams, slopers, and dipoles, I worked non-stop for the entire weekend without once turning off the MLA. Nearby stations running multi-element antennas checked with me several times to confirm I was running wire antennas, and one fellow actually came over to see for himself. (I attribute that mostly to the fact I'd been running substantially less power in the past.)

Power, especially when you're dealing with an amplifier like the MLA, can get away from you. I found myself running the amplifier for the sake of running it, instead of saving the power for when it was truly needed. After the excitement had worn off to some extent, I began to spend more time on CW, running 100 Watts or so on first calls, and then switching to the MLA for ego recovery purposes. It never missed!

On SSTV the MLA was a great improvement over the SB-200 mentioned earlier. Picture quality was reported much less susceptible to QSB and QRM, in direct comparison to the smaller amplifier. The interesting thing was that the MLA, running twice the power continuous duty, ran much, much cooler than the SB-200.

Considering what's ahead from the FCC, it appears the days of the super-amplifier may be numbered. Amplifiers like the MLA, which offer high power capability at a moderate



The KLM Echo 70cm transceiver.

price (and thus can be operated conservatively for longer component life), are coming into vogue. Pending FCC proposals may force future MLAs to cover only 160 through 15m, but the basic machine will remain the same. It is a highly efficient, very compact, full power linear amplifier that at $799.50 costs less per Watt than any amplifier manufactured anywhere. For a while, you may have a hard time finding an MLA-2500 at your local dealers . . . but on the basis of our experience, it's well worth the wait. *Dentron Radio Company, 2100 Enterprise Parkway, Twinsburg OH 44087.*

Bennington NH

USER IMPRESSIONS OF KLM ECHO 70CM SSB UHF TRANSCEIVER

Are you ready for the Phase III OSCAR satellites? If you are an amateur satellite enthusiast, you probably know that the new series of birds will be the first to use an assigned amateur satellite band: 435 MHz. The first of the orbiting repeaters is due to be launched within nine months. The satellite will carry a two meter to 435 MHz transponder, which will require the Earth station to have UHF SSB receive capability. (Recall that the existing OSCAR 7 satellite *receives* on 432.) The only known commercial rig that offers 435 MHz SSB capability, as well as other functions, is the Echo 70cm, by KLM Electronics.

Many OSCAR 7 Mode B users are already familiar with the Echo 70. This ten Watt transceiver allows SSB and CW communication on the 432 and 435 MHz amateur bands. It has many features that should appeal to the UHF enthusiast. Let's take a quick look at the transceiver, starting with front panel controls. The predominant feature of the rig is a large, center-mounted knob calibrated from "01" to "47" in increments of two. These numbers correspond to 20 kHz increments in frequency, with an implied starting point at either 432.01 or 435.01 MHz. This allows a tuning range of 480 kHz in each band. Continuous coverage within each 20 kHz segment is provided by a normally centered vxo control. The vxo range on either side of zero is 10 kHz – thus the entire segment can be continuously tuned. Additionally, an RIT control is provided to clarify received SSB signals. The range of the RIT is about 2 kHz. Squelch and volume controls are mounted on the right side of the panel, with the power switch connected to the volume control.

Three push-button switches are mounted on the left side of the main tuning control, under a dual purpose meter. This meter is calibrated in S-units when receiving, and provides relative power output when the rig is on the air. One button selects upper/lower sideband. The second engages an impulse noise blanker when activated. The third switch allows any 20 kHz band segment to be continuously swept for the presence of signals. The "Auto Watcher" is most useful when the Echo 70 is being used for point-to-point Earth communications. It is only necessary to know which 20 kHz is going to be used – the scan will pinpoint the signal. The presence of the "Auto Watcher" scan is denoted by a small red lamp which is illuminated during the function.

The back panel also contains several controls. A slide switch selects the base frequency of 432 or 435 MHz. A second slide switch determines the mode of the transceiver – either SSB or CW. A final control selects the internal vfo, or allows an external device to be used. When in external mode, the panel lamp on the main tuning dial is extinguished. Jacks for key, vfo, relay, and speaker are also provided. Power for the Echo 70 is a nominal 12 V dc. KLM provides two power connectors and fuses for the rig, allowing one to be permanently connected in an auto. The antenna connector is a standard SO-238 UHF jack.

I have operated the Echo 70 on SSB, CW, through OSCAR, and on simplex. Unfortunately, there are not many stations in New England on 432 SSB, so a test had to be arranged. Receive and transmit audio quality is crisp and clear, and the vxo operates in a smooth, linear fashion as the signals are tuned. The receiver consists of a double conversion design, front-ended by a six cavity helical resonator and FET amplifier. Overload was no cause for concern, as I operated the Echo 70 in the presence of an 80 Watt signal at 446 MHz and a two meter transmitter without any problems. One unexpected bonus was obtained from the receiver. I was tuning a 2m SSB transmitter, and was able to copy the third harmonic on the Echo 70. I am sure that KLM did not design the transceiver to be used as a test instrument, but of course one must use what is available!

The transmitter section delivers better than 10 Watts into a 50 Ohm load, as measured on a Bird Model 43 wattmeter. This was sufficient to access OSCAR 7 using a home brew turnstile antenna system. The 10 Watt output is more than enough to drive an outboard amplifier for extended DX or OSCAR work.

The Echo 70 only draws five Amps under transmit, so an existing 12 V supply can probably be used to power the rig. The transceiver is a natural for OSCAR satellite work. It has the versatility to operate with existing and future birds, as the Phase III satellites will use the 435 MHz band. If you are interested in greeting the new OSCAR when it is launched, the Echo 70 is a natural! While you are waiting for the launch, look for me on OSCAR 7, Mode B. I would also be happy to arrange a QSO on 432 SSB or CW from our local test mountain.

At $495.95, the Echo 70cm is complete with microphone, internal speaker, two power cords, mobile mounting bracket, and spare lamps and fuse. *KLM Electronics, 17025 Laurel Rd., Morgan Hill CA 95037.*

NEW FREQUENCY COUNTER/GENERATOR

A unique new frequency counter/generator has been announced by Lunar Electronics. The model DX-555P is a basic 30 MHz counter with 5 digit display and 7 digit readout (with front panel scaling). The 10 MHz timebase, which includes easy zero adjust to WWV, exceeds most accuracy requirements. The built-in prescaler extends the frequency count range to 300 MHz, and is activated by a rear panel switch.

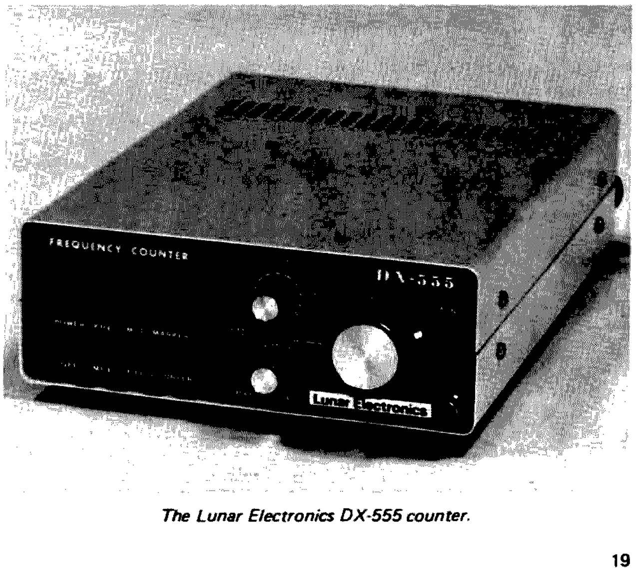
The unique part of the unit is the variable frequency marker oscillator, covering 440 kHz to 30 MHz in 3 bands. When the marker oscillator is activated by its front panel switch, its output is both available from a rear panel jack and displayed on the counter readout. The output of the marker oscillator, which also may be AM modulated with a 600 Hz tone, is of sufficient strength to align receivers down to the 455 kHz i-f and up through 30 MHz. The marker oscillator, which also includes a front panel fine tune adjust, serves as a highly accurate and economical frequency source in lieu of much more expensive frequency synthesizers.

Uses are innumerable, including the many varied counter applications through VHF and CB. The marker oscillator allows alignment of receivers in the HF spectrum, including their 455 kHz i-fs. The high harmonic output of the marker oscillator may also be used through the lower VHF range with careful attention to frequency, which will preclude aligning on the image. SWL users can easily set their receivers to the frequency listed for a foreign broadcast station without having to hunt across the receiver's usually inadequately accurate dial for the station of interest. Besides the SWLers, CBers, and bench technicians mentioned above, other users would include radio amateurs, experimenters, field technicians, and many others.

The model DX-555P counter/generator with prescaler lists at $239.95. The unit is also available without the prescaler at $189.95. Units may be obtained via dealers, or direct from Lunar Electronics. *Lunar Electronics, PO Box 82183, San Diego CA 92138.*

THREE NEW COUNTERS FROM YAESU

The introduction of a new line of three frequency counters, designated as YC-500, has been announced by Yaesu Electronics Corporation. The three models offered are the YC-500J (with an accuracy of 10 PPM), the



The Lunar Electronics DX-555 counter.

The Yaesu YC-500J frequency counter.

YC-500S (at 1 PPM), and the YC-500E (at 0.02 PPM). All three counters provide six display digits and cover the range of 10 Hz to 500 MHz. Two separate inputs are provided, one covering 10 Hz to 50 MHz, and the second, 50 MHz to 500 MHz.

A built-in ac or dc supply provides for complete portability. Advanced IC techniques are used in the circuit design, and a double-sided computer quality circuit board ensures stable and extremely accurate operation for many years.

The counters are now on display at all authorized Yaesu dealers throughout the United States. A copy of the operating manual may be purchased for $4.50 postpaid from *Yaesu Electronics Corporation, PO Box 498, 15954 Downey Avenue, Paramount CA 90723.*

NEW HUSTLER AMATEUR ANTENNA CATALOG

A brand new catalog describing the entire line of Hustler amateur HF, VHF, and UHF antennas has just been published by New-Tronics Corporation in Cleveland, Ohio. New-Tronics is the originator of the Hustler brand of amateur and CB antennas.

Hustler's new amateur antenna catalog contains more than 40 antennas and accessories. Featured products include the new no rip-off "Hustloff" trunk lip mount that does not require drilled holes. A turn of a knob removes or mounts the entire antenna assembly on the side or edge of a trunk lid, all without disconnecting the cable. The antenna assembly stores easily inside most trunks. Test data shows that the solid grounding of the "Hustloff" mount provides the user with consistent performance under any conditions – plus far greater range potential, compared to other available rob-proof mounts (including the magnetic and hinged flip-out variety).

Another featured item is the improved performance built into the base-loaded 5/8 wavelength BBLT and BBL series of two meter mobile antennas with 3.4 dB gain (compared to a 1/4 wave ground plane).

Other products include a fixed station four band vertical antenna (one setting for 10, 15, 20, and 40 meter coverage), a fixed station two meter vertical with 6 dB gain (compared to a 1/2 wave dipole), and a variety of mobile antennas for 2, 6, 10, 15, 20, 40, 75 and 80 meters, as well as 140 to 500 MHz operation.

A copy of Hustler's new amateur antenna catalog is available by writing to: Sales Department, *New-Tronics Corporation, 15800 Commerce Park Drive, Cleveland OH 44142.*

NEW SMALL-SHANK ELECTRONIC TECHNICIAN DRILL

Wahl Clipper Corporation has introduced a compact electric drill that accommodates drills and burrs with a shank size up to .123 (1/8"). The ISO-TIP electronic technician drill is ideal for prototype development, circuit board revision and redesign, solder removal, lead hole cleaning, and a variety of other jobs. Its compact size (less than 5" minus drill bit) allows use of the drill in confined areas and within cabinetry. High impact plastic housing makes it lightweight, and an extra long 10' cord provides a wide working radius. An on/off switch provides both "intermittent-on" and "locked-on" positions for convenience.

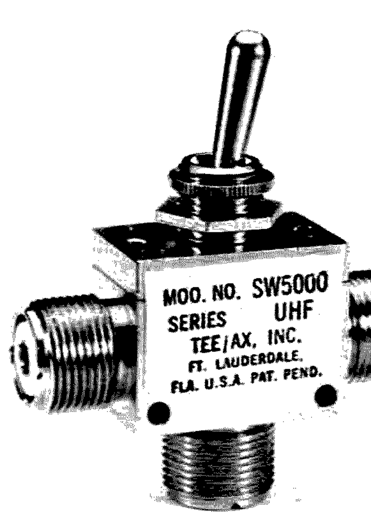
Operating at approximately 9,000 rpm, the drill is supplied with a collet chuck, 3 collets, and 2 drill bits (#56 and #71). The no. 6275 kit features a 110 V transformer power source, while the no. 6280 kits features a 12 V cigarette lighter plug assembly for on-the-spot drilling capability. Burrs, abrasive wheels, or discs can be added to expand the drill's versatility to carve, shape, form, or rout on wood, plastic, leather, and a variety of materials. *Wahl Clipper Corporation, 2902 Locust Street, Sterling IL 61081.*

The ISO-TIP electronic technician drill.

FIRST COAX TOGGLE SWITCH

TEE/AX, Inc. of Ft. Lauderdale, Florida, has announced (after nine years of development) the first complete line of coax switches with features not previously available in coax switching. The TEE/AX coaxial toggle switches are available in every series, from SPST to 6PDT. The erector set construction of the switches allows the user to stack a VHF, BNC, TNC, and SMC in one switch. By removing the top place or toggle, you can replace it with a variety of solenoids to allow using the TEE/AX as a relay. The coax switch is fully designed to survive in any environment (such as that in aircraft, where shock and vibration are a factor). The TEE/AX coaxial switches are 100% anti-shock proof.

TEE/AX, Inc., will also fabricate coaxing switching systems and custom coax switches to specific customer needs. Over 300 variations of switches and relays will be available. Technical specifications are available on the entire coax switch line. *TEE/AX, Inc., 5701 NW 31st Ave., Fort Lauderdale FL 33309.*



The TEE/AX coax toggle switch.

COMPUTERIZED MORSE CODE RECEPTION PACKAGE

Polaris Computer Systems has announced the development of a Morse code reception package for the S-100-based 8080 microcomputer. The package consists of a tone-to-dc converter module and complete software. The converter connects to the communications receiver via headphone jacks and to the computer via a parallel I/O port.

The converter contains a phase locked loop for tone decoding, and adjustable center frequency and bandwidth controls. Its design is highly immune to impulse noise. Provision for audio and visual synchronization of the incoming signal is provided.

The software adjusts for variations in transmission as each code element is received, allowing for manual or automatic transmission of CW at speeds ranging from 5 to 60 words per minute. Noise and dropout negating logic is included. The final output of received text is to an SIO port for display to a printer or CRT.

The package price in kit form for the converter, object program, and complete documentation is $95.00. An assembled and tested version lists at $145.00. Source tapes and complete turnkey packages are also available. On the low end, schematic of the converter, object dump, and documentation are available for $17.00. *Polaris Computer Systems, 3311 Richmond Avenue, Houston TX 77098.*

HEATH ANNOUNCES PERSONAL COMPUTERS

The latest entry into the hobby computer field is Heath, the popular manufacturer of electronic kits. The long-awaited computer product line consists of two processors, a video terminal, and an array of peripheral I/O devices.

Heath chose the widely available 8080 8-bit microprocessor as the basis for the H8 computer. The other computer, dubbed the H11, is based on the Digital Equipment Corporation (DEC) LSI-11 computer, which is a 16-bit minicomputer.

Targeted for release this summer, the H8 computer features an intelligent front panel with octal display and data entry capability. One-button program loading is provided by a resident monitor and built-in bootstrap program. Sixteen push-buttons are provided for data entry, and an LED display allows machine states and register contents to be displayed. A speaker is built into the H8 to allow special programming effects.

The H8 computer features a 1K ROM that contains the monitor program and bootstrap. The machine has a memory capacity of 65K bytes. The mainframe utilizes 50 pin connectors, of which 10 are available for memory and peripheral controllers. The built-in power supply can support the CPU, 32K of memory, and two I/O devices. The price for the basic H8 computer kit is $375.

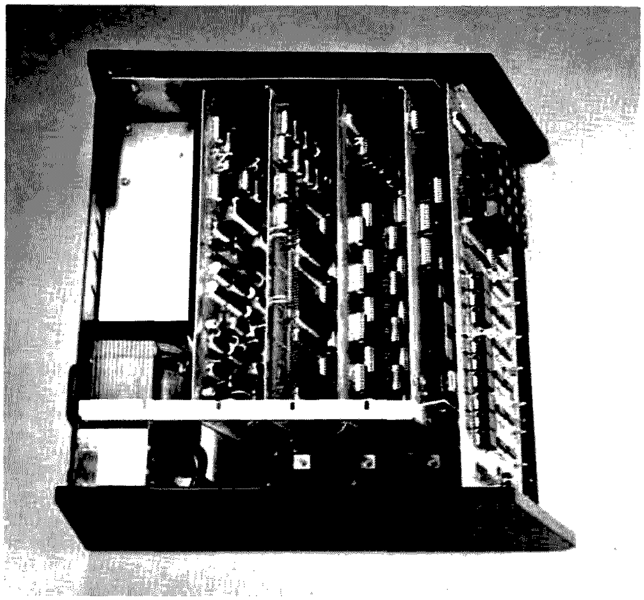
Heath has bridged the 8-bit gap with the H11 computer, to be shipped this fall. Based on DEC's powerful LSI-11 computer board, the H11 is a full 16-bit machine that features the DEC PDP-11 instruction set. The H11's CPU board is fully wired and tested. The LSI-11 board features 4K x 16 RAM, expandable to 20K. A switching power supply is standard, as is full circuit protection and a wired backplane. Interfaces initially consist of serial and parallel I/O modules. A 4K memory board is also available.

However, one of the most attractive features of the H11 is the software provided by Digital Equipment Corp. An assembler, editor, linker, and debug package is provided, as well as the BASIC and FOCAL languages. Owners of the H11 will also be able to use programs from the extensive DEC users group, DECUS.

A complete line of peripheral devices is available to support the H8 and H11 computers. A CRT display and paper tape reader/punch, designated the H9 and H10 respectively, will allow I/O capability. The following products will be available from Heath when H8 and H11 production commences:

H8	8080 Computer	$375
H8-1	4K Memory	140
H8-2	Parallel Interface	150
H8-3	4K Chip Set	95
H8-5	Serial/Cassette Interface	110
H9	Video Terminal	530
H10	Paper Tape Device	350
H11	LSI-11 Computer	1295
H11-1	4K memory	275
H11-2	Parallel Interface	95
H11-5	Serial Interface	95

The listed equipment is in kit form from *Heath Company, Benton Harbor MI 49022.*



Inside the H8: Heavy-duty power supply is visible, as well as the ten slot mother board.

Heathkit H11 Computer, based upon the DEC LSI-11.

The Heath 8-bit family: H9 Video Display, H8 Computer, and H10 Paper Tape Reader/Punch.

CONTESTS

EUROPEAN DX CONTEST
CW
Starts: 0000 GMT, Saturday, Aug. 13
Ends: 2400 GMT, Sunday, Aug. 14
Phone
Starts: 0000 GMT, Saturday, Sept. 10
Ends: 2400 GMT, Sunday, Sept. 11
RTTY
Starts: 0000 GMT, Saturday, Nov. 12
Ends: 2400 GMT, Sunday, Nov. 13

Sponsored by the Deutscher ARC (DARC), this contest is open to all amateurs, who may use all amateur bands, 3.5 to 28 MHz. Classes include single op/all band and multi-op/single transmitter. Only 36 hours of operation out of the 48 hours are permitted for single op stations. The 12 hours of non-operation may be taken in not more than three periods anytime during the contest. Each station may be worked once per band. A contest QSO can only be established between a non-European and a European station, except in the RTTY section, where contacts between all continents and one's own continent are permitted.

EXCHANGE:

An exchange consists of the usual 5 or 6 digit serial number, RS(T) report, plus progressive QSO number starting with 001.

SCORING:

Each QSO counts 1 point. Each confirmed QTC (given or received) counts 1 point (see below). The multiplier for non-European stations is determined by the number of European countries worked on each band. Europeans will use the last ARRL countries list. In addition, each call area in the following countries will be considered a multiplier: JA, PY, VE, VO, VK, W/K, ZL, ZS, UA9Ø. The multiplier on 3.5 MHz will be multiplied by four, on 7 MHz by three, and on 14 to 28 MHz by two. The final score is the total QSO points plus QTC points multiplied by the sum total multipliers from all bands.

QTC TRAFFIC:

Additional point credit can be realized by making use of the QTC traffic feature. A QTC is a report of a confirmed QSO that has taken place earlier in the contest and later been sent back to a European station. It can only be sent from a non-European station to a European station. The general idea is that after a number of European stations have been worked, a list of these stations can be reported back during a QSO with another station. An additional one point credit can be claimed for each station reported. For RTTY section only, QTC traffic is allowed between all stations (sent and received), but not between stations in the same country. A QTC contains the time, call and QSO number of the station being reported. Example: 1300/DA1AA/134. This means that at 1300 GMT you worked DA1AA and received number 134. A QSO can be reported only once, and not back to the originating station. Only a maximum of 10 QTCs to a station is permitted. You may work the same station several times to complete this quota, but only the original contact, however, has a QSO point value. Keep a uniform list of QTCs sent. QTC3/7 indicates that this is the 3rd series of QTCs sent and that 7 QSOs are reported. Europeans may keep the list of received QTCs on a separate sheet, if they clearly indicate the station which sent the QTCs.

ENTRIES AND AWARDS:

Certificates to highest scorer in each class in each country, reasonable score provided. Continental leaders will be honored. Certificates also given to stations with at least half the score of the continental leader. Violation of the rules, unsportsmanlike conduct, or taking credit for excessive duplicate contacts will be deemed sufficient cause for disqualification. The decisions of the contest committee are final. It is suggested to use the log sheets of the DARC or equivalent. Send a large size SASE to get the desired number of log and summary sheets (40 QSOs or QTCs per sheet). Mailing deadlines are: CW Sept. 15th; Phone Oct. 15th; RTTY Dec. 1st. Entries should be addressed to: WAEDC – Committee, Post Box 262, D-895 Kaufbeuren, Germany. North American residents may send their entries to: Hartwin E. Weiss WA3KWD, 323 North Street, Millersburg PA 17061 USA. Minimal requirements for a certificate or trophy are 100 QSOs or 10,000 points. European country list is same as shown for EURD awards!

Special note – Please keep the following sections free of contest activity. CW: 3550-3800, 14075-14350, 21100-21450, 28100-29700. Phone: 3650-3750, 14300-14350, 21400-21450, 28700-29700.

CAN-AM CHAMPIONSHIP CONTEST
Phone
Starts: 0200 GMT, Aug. 20
Ends: 2400 GMT, Aug. 20
CW
Starts: 0400 GMT, Aug. 21
Ends: 0200 GMT, Aug. 22

OBJECTIVE:

To increase the communication and friendship between the Canadian and American amateurs and to provide the means of measuring the performance of their operating skills and equipment.

BANDS:

All bands 1.8 through 28 MHz are permitted; general portion of the bands is recommended for use on phone and CW.

CATEGORY OF COMPETITION:

1. Single operator – stations operated by the station license holder.
2. Multi-operator, single transmitter – stations operated by one or more operators other than the licensee.
3. Club competition.

EXCHANGE:

Signal report, RS on phone and RST on CW, plus sequential QSO number starting with 001, plus multiplier area abbreviation, i.e., 59001CT or 599001ON. Multiplier area abbreviation is the usual two letter postal abbreviation for 50 US states, CN – Caribbean (KC4, KG4, KP4, KS4, KV4, KZ5), PC – Pacific (rest of US possessions). Canadians will use: NL – V01, V02; NB – VE1 New Brunswick; NS – Nova Scotia; PE – Prince Edward Isl.; SI – Sable and St. Paul Isl.; PQ – VE2; ON – VE3; MB – VE4; SK – VE5; AT – VE6; BC – VE7; NW – VE8 NWT; YU – Yukon.

MULTIPLIERS:

50 US states, 2 US possessions (Caribbean, Pacific); 10 Canandian provinces, 2 territories (NWT, Yukon), 1 Islands (Sable, St. Paul).

Total of 65 multipliers per band; maximum possible on all bands is 390.

POINTS:

1. Americans to Americans, Canadians to Canadians QSOs count for 2 points.
2. Americans to Canadians and vice versa QSOs count for 3 points.

The same station can be contacted once on each band and mode. Stations operating from outside of their own call area must sign slash and the area they are operating from, i.e., W6AM/7, W2PV/KH6, KP4AST/W2.

SCORING:

The final score is the result of the total QSO points from all bands, multiplied by the sum of the multipliers from all bands. Phone and CW sections of the contest are considered separate contests. However, combined scores of phone and CW will be used for overall competition. Combined scores will be calculated as a result of the addition of phone and CW scores.

AWARDS:

First place certificates will be awarded in each multiplier area on both modes in single operator category. Top five multi-operator stations will receive certificates. (Combined phone and CW scores will be considered.) Free one year subscription to *LONG SKIP* – The CANADX bulletin

– will be awarded to the top 5 stations overall in both categories.

TROPHIES AND PLAQUES:

1. Single operator, overall – Canadian champion, American champion.
2. Single operator, phone – Canadian champion, American champion.
3. Single operator, CW – Canadian champion, American champion.
4. Multi-operator champion.

Each station is eligible for one trophy only. In a case where one station would qualify for another trophy, the less significant trophy goes to the next eligible station.

CLUB COMPETITION:

A handsome plaque will be awarded to the club submitting the highest aggregate score of the phone and CW scores submitted by its members under the same rules as CQ WW contest.

LOG INSTRUCTIONS:

All times must be kept in GMT. Indicate multiplier the first time only on each band. Log must be checked for duplicate contacts, correct QSO points, and multipliers. Do not use separate logs for each band. Each entry must be accompanied by a summary sheet showing all scoring information, category of competition, operator's name and callsign, address of the station, and signed declaration. Entries with over 200 contacts must include check sheets for each band. Official logs, check sheets, and summary sheets are available from CANADX – a large SASE will bring you samples.

DISQUALIFICATION:

Violation of amateur radio regulations in the country of the contestant or the rules of the contest, unsportsmanlike conduct, or taking credit for excessive duplicate contacts or unverifiable QSOs or multipliers will be deemed sufficient cause for disqualification. (Incorrectly logged calls will be counted as unverifiable contacts.) Actions and decisions of the CANADX contest committee are official and final.

DEADLINE:

All entries must be postmarked no later than September 30, 1977, and mailed to: Canadian DX Assn. – CC, Box 717, Station Q, Toronto, Ont. M4T 2N7, Canada.

NEW JERSEY QSO PARTY

Contest Periods:
2000 GMT, Saturday, Aug. 20 to
0700 GMT, Sunday, Aug. 21;
1300 GMT, Sunday, Aug. 21 to
0200 GMT, Monday, Aug. 22

The Englewood ARA invites all amateurs worldwide to take part in this year's annual contest. Phone and CW are considered the same contest. A station may be contacted once on each band and mode; CW contacts may not be made in phone band segments. NJ stations may work other NJ stations. General call is "CQ NJ". NJ stations are requested to identify themselves by signing "DE NJ". Stations planning active participation in NJ are requested to advise the EARA by August 6th of their intentions, so that full coverage from all counties can be planned. Portable and mobile operation is encouraged.

FREQUENCIES:

1810, 3535, 3905. 7035, 7135, 7235, 14035, 14280, 21100, 21355, 28100, 28600, 50-50.5, 144-146. Suggest phone activity on the even hours, 15 meters on the odd hours between 1500 and 2100 GMT, 160 meters at 0500 GMT.

EXCHANGE:

QSO number, RS(T), and QTH (NJ-county, others – ARRL section).

SCORING:

Non-NJ stations multiply number of completed QSOs times number of NJ counties worked (21 max.). NJ stations score 1 point per US/Canadian QSO, 3 points per DX QSO, and multiply total QSO points times number of ARRL sections (including NNJ and SNJ). KP4, KH6, KL7, KZ5, etc., count as 3 point DX contacts and as section multipliers.

ENTRIES AND AWARDS:

Certificates to first place NJ station in each county, and first place in each ARRL section and country. Second place certificates when four or more logs are received. Novice and Tech certificates also to be given. Logs must show date/time in GMT, band, emission, etc., and be received not later than Sept. 17th. The first contact for each claimed multiplier must be indicated and numbered, and a checklist of contacts and multipliers should be included. Multi-op stations should be noted and all calls listed. Logs and comments should be sent to: Englewood ARA, 303 Tenafly Road, Englewood NJ 07631.

REPUBLIC OF TRINIDAD AND TOBAGO QSO PARTY

Starts: 0000 GMT, Saturday, Aug. 27
Ends: 2400 GMT, Sunday, Aug. 28

This QSO party was organized by the Trinidad and Tobago ARSoc to commemorate the first anniversary of the Republic of Trinidad and Tobago. Use any band/mode, 10 through 160 meters, and OSCAR/SSB.

EXCHANGE:

Usual 5 and 6 digit exchange consisting of the RS(T) and serial number starting from 001.

AWARDS:

A certificate will be awarded to any station working 5 or more 9Y4 stations. Contacts may be on different bands, but must be in the same mode! A certificate with endorsement sticker and QSL cards confirming contacts will be awarded to stations working 9Y4 on five bands, all contacts in the same mode.

ENTRIES:

Logs should show date/time in GMT, stations worked, number sent/received. Logs only required for five station awards; QSLs required along with log for five band award. Include a remittance of $1.00 or IRC equivalent with logs if eligible for an award. Entries must be postmarked no later than Oct. 15th to: TTARS, PO Box 1167, Port of Spain, Trinidad, West Indies.

OHIO INTERSTATE QSO PARTY

Contest Periods:
1600 to 0200 GMT each day, Aug. 27 and 28

Co-sponsored by the Ohio Council of Amateur Radio Clubs and the Farout Amateur Radio Club of Kettering. This contest replaces the two contests originally planned by the two groups! Rules are as follows: Out of state stations work Ohio stations only; OH stations work any station. Each station may be worked once per band and mode. Multi-xmtr, multi-op stations are allowed, but are ineligible for awards. Repeater contacts are not allowed, except through OSCAR.

EXCHANGE:

Serial number, RS(T), and ARRL section or country – or OH county for OH stations.

SCORING:

Score 1 point per QSO. Add 50 points to final score for working Ohio State Fair Station NO8HIO. Multiply score by 1.5 for operating portable using temporary power and antennas in any OH county except Butler, Clark, Cuyahoga, Franklin, Hamilton, Lake, Lorain, Lucas, Mahoning, Montgomery, Portage, Richland, Stark, Summit, or Trumbull.

Note: The latest copy of the rules omitted the scoring multiplier, so I would assume that it would be the number of Ohio counties for non-Ohio stations and the number of ARRL sections for Ohio stations.

FREQUENCIES:

5 kHz up from lower edge of General class band.

ENTRIES/AWARDS:

Entries should include logs showing time, band, mode, and exchange info, summary sheet claiming score, and return mail address. Include an SASE for results. Logs must be postmarked by Sept. 15, and should be sent to: Joe WB8HWE, Box 7825, SR188, Circleville OH 43133. Trophies to highest OH and out of state. Certificates to top OH in each county and each ARRL section and DX score. Participation certificate to each entrant with 50 or more QSOs. Special certificate for working 3 or more Farout ARC members.

W8MBI

The Ohio Buckeye Belles will be operating their memorial station W8MBI (and individually) during the Ohio Interstate QSO Party, giving everyone an excellent opportunity to work Ohio YLs. The Buckeye Belles award a certificate to OH stations for 12 confirmed QSOs, to other US stations for 8 confirmed QSOs, and to DX stations for 4 confirmed QSOs. Send complete log data – name, call, date, time, band, mode, and Buckeye Belle numbers – to Certificate Custodian Marge K8ITF, 1608 Randeley Avenue, Dayton OH 45403. Please include 50¢ to help cover mailing costs.

EURD

Congratulations to Bruce Balla VE2QO, who was the first non-European station to obtain the RTTY Award EURD-3 from DARC. As of this writing, he is one of ten amateurs to receive this award – only three have made it to the top (EURD-1).

Dual Rhombic For VHF-UHF

-- work some DX!

Bill Parker W8DMR
2738 Floribunda Drive
Columbus OH 43209

What single antenna can provide 26 dB of gain over a half wave dipole and also

(a) exhibit relatively low wind resistance;
(b) operate over a bandwidth approaching twice the design frequency;
(c) permit shared mast mounting with other antennas for ease of rotation;
(d) is easy and not overly time-consuming to construct; and
(e) is light of weight and inexpensive (under $20) too?

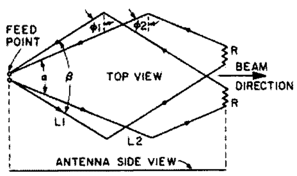

Fig. 1. Dual rhomboid antenna configuration.

A parabolic dish cannot. The optimum spaced long yagi cannot. A collinear array cannot. Nor can the log periodic, corner reflector, helix, or any other antenna. The dual rhomboid *can!*

The need for high antenna gain still exists. High gain antennas (in excess of 20 dB) are very directional antennas providing beamwidths between 5 and 10 degrees. Antenna gains greater than 30 dB produce half power beamwidths of less than 5 degrees and require very accurate pointing systems. Antennas with gain exceeding 20 dB are used on VHF, UHF, and higher. For best results at these frequencies, the antenna must be placed high and above the surrounding obstructions. Wind loading produced by such mast-mounted rotatable antennas at the top of the tower cannot be ignored if the antenna system is to survive.

Can you imagine a 21 foot diameter parabolic dish antenna[1] (required to produce 26 dB of gain) mast-mounted and rotatable on a 50 foot tower in a 50 mph wind? Even with the reflector constructed of 1 inch wire mesh? Over 750,000 foot-pounds of torque will be generated at the base of the tower. And that is without any additional antennas or any additional mast height. The dish antenna (excluding satellite work) to be effective requires a structure and platform to support it. Construction of the dish antenna is not the easiest of tasks.

The long yagi certainly has less wind resistance. An optimum spaced long yagi[2] requires a 100 foot boom to yield 26 dB of gain. It is easier to construct and could be made light in weight. But the 1 to 1.5 percent bandwidth of the operating frequency limits the usefulness, especially on the 420-450 MHz band. Stacking two 50 foot boom long yagis could be done with some ease. The stacking distance will require a mast extending out of the top of the tower in excess of 25 feet if the equivalent 26 dB of gain is to be realized. The torque loads created in starting and stopping a 100 foot boom represent an additional problem for the rotator mechanism. The swaying of a high gain long yagi antenna during gusty wind produces signal variations during both transmit and receive (similar to QSB created by atmospheric changes along the signal path).

Consider a 26 dB gain collinear array antenna. The array would have a lot less wind resistance than the dish antenna. It would also exhibit more bandwidth than the yagi. It would require, however, an array of 12 elements broadside (high) by 8 elements collinear (wide). It would take a total of 96 driven elements plus 96 reflector elements[3] to provide a gain of approximately 23 dB. To obtain the additional 3 dB for a 26 dB gain collinear array, the total array needed would contain 384 elements and a frame to support them. Even at 435 MHz, more than 384 feet of element material would be required. If the 192 reflectors were replaced with a screen mesh, more than 300 square feet would be required. Although a substantial improvement in bandwidth would be realized, a considerable increase in wind loading occurs.

The dual rhomboid antenna provides a gain of 26 dB

(an effective radiated power increase of 400 times). It has relatively low wind resistance, wide operating bandwidth, consumes little mast height, is light of weight, easy and inexpensive to construct, and is rotatable.

The dual rhomboid is of the rhombic class, but with improvements. The double rhomboid antenna[4] configuration is shown in Fig. 1. Longwire antennas always radiate large numbers of side lobes that are distributed profusely. Judicious choice of the side length and apex angle selection of the rhomboids can cause destructive interference of the unwanted and wasteful side lobes. The dual rhomboid antenna designed for a high order of side lobe suppression at one frequency retains this characteristic very well over a substantial frequency range. This is not possible with a single rhombus.

The design principles involved are the same as for the "V" antenna and the rhombus antennas. The angles (referred to as tilt angles) were expressly selected for zero angle radiation from each rhomboid[5]. Since most antennas of the rhombus class operate against ground (heights of less than one to two wavelengths), zero angle radiation tilt angles are not normally selected. See Figs. 2 and 3.

The length of sides L_1 and L_2 specifically differ by a one-half wavelength factor. The array radiation pattern is the *product* of the patterns for the component sides at all points in space.

The only connection between the rhomboids is at the common feedpoints. The antenna consists of two rhomboid elements connected in parallel at their common apex where a balanced feedline connects[6]. One terminating resistor is required for each rhomboid. The terminating resistors should be of the noninductive variety and able to withstand the weather. Each terminating resistor should be capable at least of dissipating one-fourth of the input power to the antenna. Termination values of between 600 and 800 Ohms are recommended. For example, if 10 Watts is applied at the feedpoint, each resistor should be capable of 2.5 Watts dissipation.

The list of parameters for the dual rhomboid antenna shown in Table 1 is for a design frequency of 435 MHz.

The side lengths are calculated from the following formula:

$$L\ (\text{feet}) = \frac{984\ (N - 0.05)}{\text{Freq. (MHz)}}$$

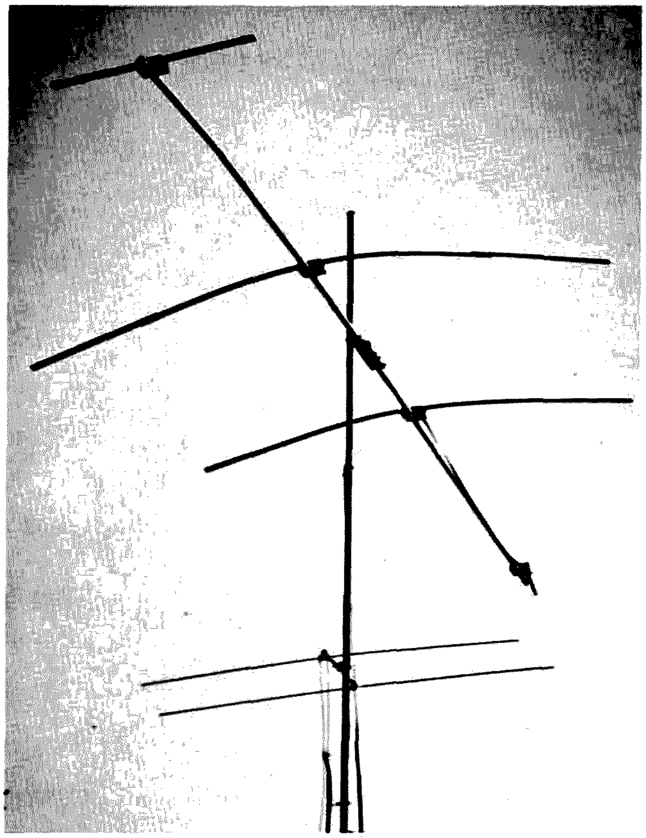
where N is the number of full waves. L_1 and L_2 for a design frequency of 435 MHz are 93.5 and 161.5 inches, respectively. The side lengths are needed to determine the boom length and the three crossarm lengths.

Apex angles α and β are derived by:

$$\alpha = 2(90 - \phi_2)$$
$$\beta = 2(90 - \phi_1)$$

and are 46 and 58 degrees, respectively. The tilt angles ϕ_1 and ϕ_2 were selected for side lengths of 3.5 and 6.0 wavelengths, as well as zero angles radiation.

The dimensions for boom, crossarms, and crossarm spacing are shown in Fig. 4.



Dual rhomboid antenna installation at WA8QQU, Reynoldsburg, Ohio.

The angle subtended between the diagonal of each rhomboid is equal to:

$$\frac{\beta - \alpha}{2} = \frac{58 - 46}{2} = 6\ \text{degrees}$$

An isosceles triangle is formed at the forward end of the beam by the rhomboids' crossover and the two terminators. Detailed specific dimensions for construction of the high gain dual rhomboid antenna whose bandwidth is essentially 420 to 890 MHz are shown in Fig. 4.

Construction

A metal boom that runs the full length of the dual rhomboid is not recommended. Excessive side lobes will be generated if this construction technique is em-

Design Center Frequency		**435 MHz**
Side length #	**$L_1 = 3.5\lambda$**	**$L_2 = 6.0\lambda$**

Apex Angle	**$\alpha = 46°$**	**$\beta = 58°$**
Beam Width *	**V = 5.8°**	**H = 9.7°**
Termination	**R = 820 Ohms**	**R = 820 Ohms**

***Half power level**
#L_1 = 7.8 feet, L_2 = 13.46 feet

Table 1. List of parameters for dual rhomboid.

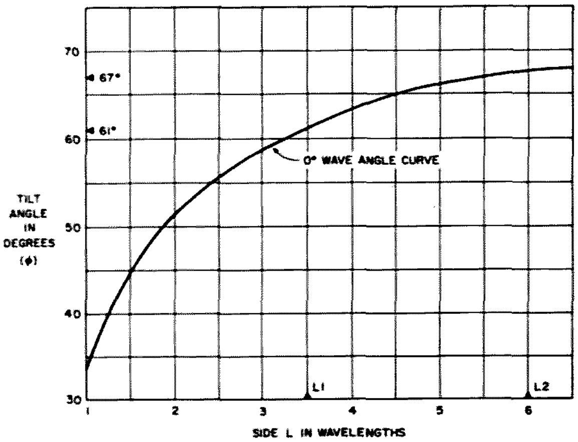

Fig. 2. Zero degree wave angle design chart.

Dual rhomboid antenna held with one hand by W8DMR's XYL. Total boom length is 20'6".

ployed. The center section of the boom should be made of metal or of material sufficiently rigid to support the nonmetallic crossarms. A total of about 86 feet of wire is required with each leg of the rhomboid being about 21½ feet long. The conductor size should be as large as the antenna frame can adequately support. Number 14 AWG solid copper, formvar coated was used in the author's dual rhomboid antenna. Even ¼ inch tubing is recommended. Although not recommended, a model used #24 AWG enameled single strand copper with some success.

The transmission line from the feedpoint to the mast should be foam 300 Ohm balanced nonshielded line. Open wire line or foam line works well. Once the feedline reaches the mast, a change to shielded 300 line or coaxial cable can be made. In the case of coaxial cable, a broad band balun should be used. If nonshielded 300 Ohm line is used, ABSOLUTELY DO NOT TAPE the feedline to any metal structure. This includes the metal section of the boom, the mast, the tower, other coaxial cables, downspouts, gutters, metal house siding, or metal sash windows. Never permit nonshielded 300 Ohm line to run along the ground or against masonry walls and floors, even if it is foam filled.

Operational Tests

The antenna has been used primarily to receive and transmit standard scan amateur TV signals. A secondary use has been to receive UHF commercial TV channels 14 through 83. The antenna has been used to receive channels 2 through 13, with less gain. The results have been excellent, with the exception that lobing was experienced on the higher UHF TV channels. The antenna has good front to back ratio. The antenna was rotated to vertical polarization to verify that the angle of radiation was truly zero. The antenna did not have a double (split) lobe in the vertical axis.

Additional Improvement

The dual rhomboid can be expanded such that it could be referred to as the quad rhomboid. This would be accomplished by adding two additional rhomboids, as in Fig. 5. There would be still a single feedpoint, but two additional terminators would

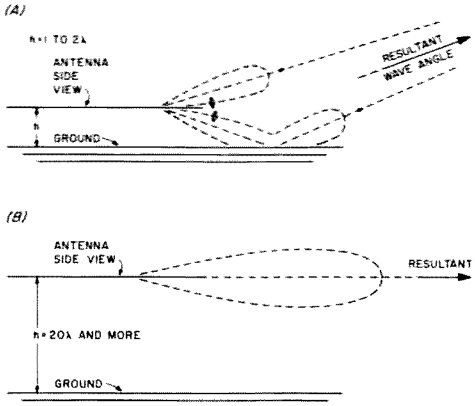

Fig. 3. Effect of tilt angle selection. (a) Non-zero angle radiation, rhombic antenna working against ground. (b) Zero angle radiation due to tilt angle selection. Note: *Tilt angle does not mean physically tilt the antenna. See Table 1.*

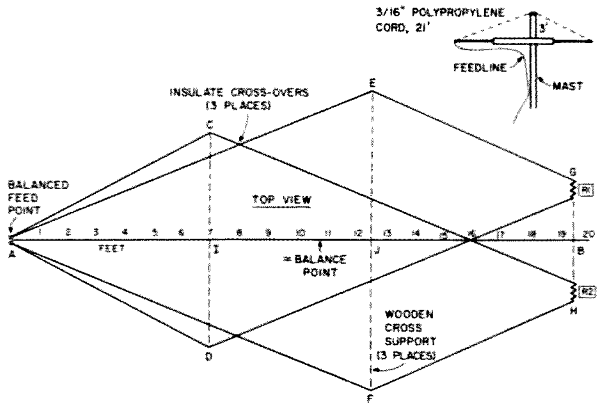

Fig. 4. Dual rhomboid antenna for 435-870 MHz. Beamwidth ≈ 10° H x 6° V. Gain over DP ≈ 26 dB. Boom length: AB = 19'6". Support spacing (see text): AI = 7'; IJ = 5'6"; JB = 7'. Support length: CD = 7'3"; EF = 10'3"; GH = 3'0". Rhomboid sides: AC, AD, EG, FH = 7'9.5"; AE, AF, CH, DG = 13'5.5". Feedline: see text. Wire needed: 14 AWG formvar, ≈ 86'0". Boom material: AI, JB = wood; IJ = metal. Cross support: CD, EF, GH = wood. Terminators: R1, R2 = 600 Ohms; Watts – see text.

be required. The feedpoint impedance would be lowered. The additional rhomboids should have different side lengths; as an example, L3 could be 2.5 wavelengths and L4 could be 7.0 wavelengths. The quad rhomboid would not require any additional mast space, as would be the case in stacking an additional dual rhomboid.

Acknowledgment

The contribution of Bob Dervin WA8QQU in field tests and experimental models is gratefully acknowledged. ■

Corrections

Just a note to let you know that in the June *73* issue, on page 176 ("Current-Saver Counter Display," Fig. 4), there is an error in the circuit. The outputs of the two 7400 chips should be bussed before driving the 7447 decoder-driver. The existing schematic is incorrect in that the outputs of the "Latch No. 1" 7400 do not drive the decoder.

Doug Marquardt WB2AWG
Bogota NJ

The article, "Aim Your Antenna With a Micro," in the June, 1977, issue of *73*, contains an unfortunate typographical error (of omission) and leaves implicit that which needs to be made explicit for some of us who not only cannot read "between the lines" but are having real difficulty with the lines themselves!

First, the omission. FORTRAN statement 290 correctly contains the minus sign (PL1 = -87.63*PIE/180) before the longitude. The corresponding BASIC statement number 170 omits this necessary minus sign.

Second, the implicit information which should have been quite explicit: The authors imply in the description of the FORTRAN program that the program contains the constants which represent the local latitude and longitude, as indeed it does. However, clarity of expression seems to dictate an *explicit* sentence or sentences such as the following:

"It should be noted that FORTRAN statements 260 and 290 contain the latitude and longitude, respectively, of Chicago, as do the corresponding BASIC statements 140 and 170. For other 'local' locations, change 41.87 and -87.63 to the proper latitude and longitude."

A couple of sentences such as the above would have been most helpful, but then I would have been deprived of a little troubleshooting and the feeling of euphoria which I experienced when I finally found out where the "bugs" were. Other than the problems above, the article was excellent and now I can swing my hybrid-quad with arrogant precision. Those who are familiar with that miniaturized rf choke of an antenna may well ask, "Why bother?" Because it provides valuable practice and experience for the time when I will finally have an antenna with a decent front-to-back ratio and appreciable gain, that's why. So don't bother me while I aim my two element mini-antenna right down that Zed-El's throat. Who knows, maybe someday he'll come back to me and I can casually give him his correct beam bearing to several decimal places!

Ronald W. Evans K5MVR
Fort Worth TX

Please note a correction to my article, "Two Meter Scanner" (June, 1977):

The power input driving the LEDs through a 430 Ohm resistor is incorrectly marked "+5 V." This point should be marked "+12 V," as the display will not function correctly with a five volt supply.

Carl A. Kollar K3JML
Nanticoke PA

In my article, "Sending HI on the Hooter," in the May, 1977, issue of *73*, a few things were overlooked. The relays, RY1 and RY2, do have some limitations on their choice. RY1 is driven by a TTL output and should pull in at 5 volts and 16 mA maximum. RY2 should pull in at 5 volts and 80 mA maximum and also have a contact capable of switching ½ Amp of inductive load.

James F. Reid W8LWS
Ashley OH

I feel that your magazine is the tops. I really enjoyed the article "Superprobe," but found one error. The pulse LED would stay on all the time. Resistor R9 is drawn on the wrong place on the schematic; it should go from pin 4 of IC2 to ground, not from pin 3 of IC2 to ground. R1 can be increased to about 5-10k to increase input impedance.

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz. OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz. Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days. An asterisk (*) indicates AO-7B-6 intersatellite link.

Microwave Waveguide Details

-- square copper tubing?

Waveguide plumbing is the designer's choice for microwave circuits operating from 2000 MHz upwards. It's generally available at surplus stores, and often quite cheaply, yet relatively few amateurs experiment with it because of its striking dissimilarities to conventional transmission line. Actually, waveguide techniques are not difficult to master, and a properly assembled system can open up a whole new radio spectrum to the experimenter.

There are a number of different types of waveguide, round, elliptical, and other shapes, but by far the most widely used is rectangular. This last is almost the only kind usually available to amateurs, so I will confine my remarks to it.

Waveguide can be described as a double wire transmission line with an infinite number of quarter wave insulators connected along it so as to form a closed tube. The means of wave propagation along it are, however, more complex than that in a two-wire line. It consists of both an electric and a magnetic field at right angles to each other which reflect from wall to wall along its length. Different modes of operation, that is, different orientations of these fields, allow more than one wave to travel through the same waveguide at the same time making it ideal for multiplexing. Circuit elements are provided by changing the properties of the inside of the tube, by altering the dimensions, by inserting obstacles into the path of the waves, by manipulating reflections, or by making cavities for the waves to resonate in. The key fact is that with waveguide it is the space inside that carries and controls the waves, rather than wires and solid components.

All waveguide components are complete units designed to be bolted into a system. This is a great advantage at microwave frequencies where the very critical measurements involved would make construction and fitting of parts a difficult task. A waveguide system is assembled more or less in the same way as an ordinary plumbing system with the notable difference that even the plain lengths of pipe are preformed so that no cutting or other machining is necessary. There are a large number of different components available, both fixed and adjustable, in a variety of sizes, corresponding to different bands of operation. All components in a system should, of course, be for the same band, so take care to measure the dimensions when buying.

The band of operation for any given size of rectangular waveguide can be determined easily from two simple formulas. The orientation of the waves at the optimum frequency is known as the dominant mode and is generally utilized. Operation outside of the dominant mode is inefficient and usually undesirable.

To find the dominant mode, divide the longer inside dimension (in inches) into 7,376, which gives the minimum desirable frequency in MHz, and then divide the same dimension into 11,136, which will give the maximum. These two frequencies span the most efficient band of operation. However, they do not represent cutoff frequencies, so there is a certain amount of leeway possible to the designer.

Energy is coupled into or out of waveguide by short probes, diodes, horns, or openings in the waveguide walls. Many microwave oscillators incorporate a section of waveguide with a probe, so they may be connected directly into a system. Others may have to be coupled by short lengths of coax. For transmitting, the system often terminates in a dipole antenna (usually backed by a reflector, the familiar radar dish) or a simple horn which serves as an impedance match to the open air. Sometimes a horn may feed into a reflector as would a dipole, and there are still other methods used, including horn arrays that act like lenses. Given care and patience, suitable antennae and reflectors can often be fabricated by an experimenter.

Waveguide sections are joined in one of two ways, either by flat, precisely matched surfaces, or by grooved, recessed "choke" flanges. The latter, although less efficient, is often used since it enables sections to be joined without extremely fine machining of their mating surfaces, thus lowering cost and improving interchangeability. There are often O-rings or thin metal gaskets between flanges to improve both the electrical and mechanical connections. With the choke connector it should be noted that only one of the mating surfaces is provided with a groove, the other being flat.

Quick-disconnect choke couplings are available, designed for use in situations where one system might have to be alternately coupled to several others, as in test equipment, for instance.

In commercial and military applications the system is usually filled with a pressurized gas, often nitrogen, both for efficiency and reliability, but experimental installations can forego this. Just be sure to keep the inside of the waveguide clean and dry. Any dust or condensed moisture will cause arcing and power loss.

The most popular method of joining waveguide flanges seems to be with small hollow-head screws and nuts, but any suitably sized fasteners will probably do. While not necessary, some attempt at torquing the fasteners equally might result

in slightly less power loss.

I can only begin to describe a few of the many types of components available for waveguide systems, those which you would be likely to have use for in a simple setup. Movable metal slugs projecting into the waveguide are used as tuning stubs to eliminate undesirable reflections, or as filters. These are often installed just after the input or just before the output. Metal or conductive plastic plates or vanes, some adjustable, some fixed, serve as attenuators by effectively changing the dimensions of the guide, and wedges or blocks of graphite or metal in the end of a section act as terminating resistors.

By far the most important group of waveguide components is that which incorporates tunable cavities which act as resonant circuits at microwave frequencies. This group includes not only passive components, but also a large percentage of microwave oscillators and amplifiers which have built-in cavities. Some oscillators, notably the magnetron, are actually little more than resonant cavities in function. A cavity used as a discrete component will often be in the form of a relatively large cylinder with one end movable, so that the size can be changed. These units are, of course, as important in microwave systems as conventional resonant circuits are at lower frequencies.

The various waveguide components are interconnected by sections of plain waveguide, available in various lengths, straight, angled, or flexible. Some are so constructed that two or more inputs are mixed into one output, others so that a fractional part of the wave energy can be drawn off for measurement or other purposes. Mechanical switches are made to transfer a wave from one guide to another, and various electronic methods have been devised to provide transmit/receive switching. In short, waveguide can be used to implement the equivalent of almost any conventional circuit.

Often complete waveguide systems can be obtained in the form of radar test sets. Such a set might include a wide band oscillator with power supply, one or more tunable cavities, usually precisely calibrated, and an assortment of waveguide sections and components, attenuators, tuning stubs, coax outputs, and impedance matches. If you can find such a unit it makes an ideal beginning in waveguide which can be added to as you see fit.

This short article is no place to go into the complex field of microwave oscillators and amplifiers, nor that of measuring devices, nor the evergrowing number of solid state components used especially in very high frequency microwave systems. Many of the newer components are not generally available to the amateur anyway. Any good microwave handbook will provide a wealth of information on these more specialized fields. Most large city libraries will have at least one such handbook, which is also must reading for anyone interested in ordinary waveguide circuitry.

With microwaves being used more and more, now is the ideal time to learn the ins and outs of waveguide, before the surplus prices start skyrocketing. In no other branch of electronics does the behavior of waves so nearly approximate physical analogies. This makes waveguide an interesting and enlightening variation on familiar theory and technique. Even if you never plan to get on the air with microwaves you will find it worth a modest investment to experiment with this unique and fascinating branch of electronic technology. ■

LETTERS

from page 7

recently took the FCC General class exam on the 9th of May, here in St. Louis. I experienced no difficulty in passing the code portion of the exam; in fact, I found it very easy to copy the material given. Unfortunately, I failed the written portion of the test. I will be trying it again in June at the Kansas City office.

Again, your tape really helped more than any other tape I have used, and I highly recommend it to other would-be General class amateurs. I am seriously thinking about tackling your 20 wpm tape.

Hanley Hills MO

STEELY-EYED

I have been an avid reader of your publications for many a year now, and far prefer them over any of the other ham magazines. I very much appreciate your policy of accepting advertising from only the most reputable firms, and also enjoy your editorial views and opinions. I must, however, take issue with one of your own advertisements – the one for the *73* code tapes.

In your text you make mention of the fact that an extra word or two per minute in code speed is necessary due to nervousness when appearing before "the steely-eyed examiner" at the FCC. I have recently returned from the Baltimore field office, General class privileges in hand. I must state that all of the personnel in the Baltimore office are anything but "steely-eyed." From the young lady administering the receiving test, to the gentleman giving the sending test, to the Engineer-in-Charge – each was most polite, kind, and did his best to put me at ease. Each did his job in a manner designed to relax the applicant and contribute to success.

I wish you would change the text of your advertisement for your excellent tapes to state that despite the sincere efforts of the friendly examiners, an extra word or two per minute is necessary to combat inevitable nervousness on the part of the applicant. Thank you.

Mayer D. Zimmerman W3GXK
Randallstown MD

LIMARC CLASSES

The Sewanhaka Central High School District, in conjunction with the Long Island Mobile Amateur Radio Club, is sponsoring a course in amateur theory and code as part of the adult education program.

LIMARC is providing the instructors while the school district is providing the facilities. There will be *no* tuition or registration fees.

Classes will be held on Wednesday evenings at Elmont Memorial High School, Elmont, L.I.

Interested persons should contact the Adult Education Office at (516) 328-4875.

John F. Gillen WA2CWT
Public Information EMHS
555 Ridge Road
Elmont NY 11003

BACK TO BASICS

I enjoy *73*, but I would like to see more basic electronic tutorial articles (how do you bias transistors, design simple amplifiers, etc.) and save the I/O stuff for *Kilobaud* (which I also get and enjoy). I don't particularly object to the computer articles, but I am a self-taught professional systems programmer, and my electronics background (and my typing) isn't very solid. I can design and get to work digital circuits (just an extension of programming, sort of), but I am almost lost in analog areas. In any case, I approve of your efforts to make computer technology more understandable to the world at large.

Stan Webb
Albuquerque NM

Get the picture, authors? – J.M.

220–NO LOSS

As an active amateur, I am in favor of the loss of up to 1 MHz of our 220 MHz band to CB for the following reasons:

1. We amateurs would really lose nothing, as we could operate on the lost frequencies with our CB license.
2. It will reduce the price of 220 MHz radios, due to mass production for us.
3. CB really needs more room at a practical low cost frequency.

I have already written the ARRL of my proposal.

Centerfed Specials

-- for the small city lot

I never believed in fancy antennas. I never read the articles on windoms and long wires and "apartment dweller" specials. Endfeds and directive arrays for the lower frequencies seemed frivolous folly. The only sensible antenna was a centerfed dipole, lovingly pruned to frequency. For years I swung these carefully constructed antennas free and clear, at a right angle to the shack, because that's what the books said to do.

Then I had to make an agonizing decision to compromise my principles or go off the air on 80 meters. I moved a proven centerfed antenna to my new house, but it wouldn't fit the lot. After days of pacing and measuring, I rationalized that it wouldn't hurt this successful dipole to – say it softly – *bend the ends just a little*. I kept telling everybody I was running a regular, run-of-the-mill 80 meter dipole, partly because I was ashamed to admit the sacrilege I'd committed, and partly because my transceiver loaded the same as always.

That first tentative transgression opened wide the door to further sin. It wasn't long before I was running drooped and twisted dipoles on several bands, and with the same good results. I reasoned these antennas succeeded because they were, after all, still the proven centerfed dipoles I had used for years even if they weren't erected by the book. Little did I know I was on the road to the ultimate sin.

In just over a year, I've moved twice and neither QTH allowed room for my comforting dipoles, no matter how I contorted them. In fact, in the first location space was so restricted (mainly because of a lease agreement) it was months before I skulled out an antenna design. In the interim, I spent the evenings hunched over an allband receiver I'd bought with proceeds from the sale of my transceiver. I strung a 20' length of wire around the room and became a shortwave listener.

A ham can listen only so long, though, so I borrowed an old Johnson Viking and hooked it right up to that same short wire. You know what? The damn thing loaded. I've got 579 reports on 40 meter CW from all over the country to prove it!

The little antenna worked so well I naturally began thinking of the companion transmitter for my state-of-the-art receiver. Before the new unit arrived, I decided to put up a real endfed antenna outdoors, a design I hadn't seriously considered before (perhaps necessity really is the mother of invention).

Now, I don't want to do anything to refuel the swr controversy – honest. But I feel compelled to write about my conversion and what I've learned about practical antenna design because of it.

I read the antenna books, then bought some 300 Ohm balanced line and a 4:1 balun. I managed to get 250' of wire in the air and fed it at the end with 100' of the balanced line, attached the balun and ran coax on into the shack. I had no swr bridge or tuner, but I got a good solid dip and could load my transmitter on all bands with no RFI problems – never mind that the books say this kind of antenna requires a matching device to function properly.

I was really corrupted by this point, so when I moved again I didn't hesitate even a day getting up an antenna. I didn't bother with the balanced line for this one. I stretched 100' of wire and endfed it with coax and the 4:1 balun. The shorter wire seems a little more sensitive to frequency change than the

$$N = \frac{fL + 24.6}{984}$$

$$Swr = \frac{R}{Z} \text{ when Z is larger than R}$$

$$Swr = \frac{Z}{R} \text{ when R is larger than Z}$$

where f: Frequency in MHz
L: 250'
N: Number of wavelengths for antenna
R: Antenna radiation resistance (see text)
Z: Feedline impedance

Fig. 1. Swr for a 250' endfed antenna.

longer model, but I still get good loading and a solid dip on any frequency on all six high frequency ham bands. There's still no outboard tuner or swr bridge in the circuit.

I keep daily CW and phone schedules with a fellow ham in South Carolina, and we've been plotting signal strengths on 80 and 40 meters since we started the contacts about six months ago. Bill K4WGP reports that no noticeable change in signal strength occurred when I changed from the 250' antenna to the 100' model.

Now for the theory part of this discussion. If we can agree with Rayer ("Exploding the SWR Myth," *73*, Dec., '76) that as long as you get a good dip from your transmitter, a tuner won't change the amount of antenna current flowing in the line (or your signal at the other end), then we can discuss theoretical swr and make happy all those people who just won't fire up their rigs unless the swr is less than 2:1.

Swr is a factor of antenna and feedline impedance. Feedline impedance for ham purposes is easy to determine because we buy lines with published impedances for specific purposes. Antenna impedance is another matter. This figure depends on the radiation resistance, height above ground, proximity to nearby objects and conductor size. For most HF ham antennas, the practical impedance usually can be considered to be the radiation resistance. For a centerfed, half wave antenna, that figure is between 60 and 70 Ohms — perhaps higher or lower depending on influences which take the antenna away from the theoretical ideal.

The figures become somewhat more complicated when an allband design is considered. As the operating frequency is moved from resonance, antenna reactance begins influencing impedance. The change is a cyclic one and interestingly enough the rate of impedance change decreases as frequency increases, assuming the antenna length stays the same. I have found by practical experience that when using an endfed wire of sufficient length, its radiation resistance is a good enough impedance figure for ham purposes.

If we start with a half wave antenna fed at a current loop, at the end in this case, the radiation resistance is approximately 70 Ohms. If the operating frequency is increased or the antenna is made longer, the resistance also increases. A one wavelength antenna has a radiation resistance of about 90 Ohms, and a ten wavelength wire will show about 160 Ohms.

Knowing the radiation resistance and the impedance of the feedline, we can compute the theoretical swr of the system. This is done in the accompanying charts for three different antennas operated on the various HF ham bands. Obviously, if you started with a desired operating frequency and juggled the antenna length, you could improve the swr at your favorite frequency. I used the beginning frequency of the bands for computations for convenience, since everyone has his favorite band or set of frequencies.

Swr for Different Feedline Impedances

28	2.9	128	1.3	2.3	1.2	1.7	2.6

Fig. 2. Swr for a 100' endfed antenna.

See Fig. 1 for a rundown of swr for the 250' antenna previously described with different feedline configurations. If the formulas are correct, one could operate this antenna at about 1.5:1 on all bands by feeding it with a 110 Ohm line. The median feedpoint resistance is (70 + 150)/2. A match almost as good can be obtained by using a more conventional 75 Ohm line. This line would keep the theoretical swr at 2:1 or less on all bands. If you use coax, you probably should add a 1:1 balun at the antenna feedpoint.

Fig. 2 is a similar chart for the 100' antenna I'm presently using. Both of these antenna lengths were chosen because they represent the maximum amount of wire I could get into the air. The table shows I'd probably be better off with a 1:1 balun and 75 Ohm feedline, but the 4:1 balun is what I had.

I ran the figures for a 135' antenna because that's a length frequently recommended for a long wire, and it is about the length of an 80 meter dipole. Many hams manage to get up the conventional 80 meter antenna but don't think they have room for an allband design.

Note, too, that you get another plus as the frequency is increased or the antenna is made longer: directivity. When an endfed design is a half wavelength long, its gain is about the same as a centerfed design. The longer the antenna (the more wavelengths on the wire), the greater the gain. The direction of increased radiation is off the ends of the antenna, so at higher frequencies especially, it often helps to lay out your endfed wire with the help of a compass so you'll get greatest directivity in the direction you're most interested in working.

So practice and theory show that for getting out, an antenna tuner or swr meter is unnecessary. There may, of course, be feedline and antenna length combinations which are beyond the capabilities of a given transmitter circuit, and there is less likelihood of harmonic radiation with a tuner.

But I've shown by personal experience and theory that slavish dedication to often-repeated facts about swr and antenna design can knock you off the air. When you need an antenna you just know you don't have room for, string up something anyway. Feed it at the end using the formulas to help you choose a feedline, make sure you're not causing RFI somewhere, and if it'll load, you can work about anything you can hear. ■

Recycle Your Receiver

-- tips for hamfest specials

I guess I'm the kind of ham that you would have to call a receiver nut. For about twenty-five years I have had the opportunity to own most of the commercial receivers available to hams. Many of these were outstanding, high quality, instruments which were a pleasure to own and use, and, of course, some were very poor, almost useless.

Unfortunately, today most receiving instruments are only a part of a transceiver. It is difficult to buy a quality receiver by itself, especially on a budget. The obvious solution is purchasing an older receiver and reconditioning it both mechanically and electrically. If you are a real receiver nut like myself, you will also consider a face lift for the old beauty. I imagine the antique car buffs would understand that quirk in my personality.

The reason I decided to rebuild the Hammarlund BC-779-B is very simple. Someone was kind enough to give me one. It also was an excellent receiver in its day, the early and middle forties – shades of Glenn Miller!

It also is an eighteen tube gem, the first of the Super-Pros, with one of my favorite characteristics, the external power supply. This is a great way to keep heat and intense magnetic fields out of the receiver proper. It has a fine quality sliding band switch which proved perfectly troublefree after all those years of use. It tunes to twenty MHz, has a good crystal filter, and enough BFO injection and stability to work reasonably well on SSB. Something like that could cost several hundred dollars new and only weigh a fraction of this boat anchor.

Now that I have established the fact that this project is worth the effort, let me give you some tips for the successful completion of this labor of love and lunacy.

I would suggest that before you begin any major work on this project that you check to see that the machine works. It does not have to be in top notch order, but it is helpful to establish this before you begin disassembly. A schematic, or better yet a manual, can be a real lifesaver. I was lucky to be able to purchase one from Fair Radio Sales. Other sources might be W3LHD for military surplus equipment, Sams Photofact, or the manufacturer.

The power supply for my BC-779-B was in terrible condition and weighed more than the receiver. It looked like it had been dropped from an airplane or run over by a tank in World War II. I built a new, much lighter supply, that I could easily store under my operating table. I added some voltage regulation for oscillator voltages and screen voltages. The screen voltage made a large change in the receiver gain for less than a five percent change in the supply voltage. I went all the way and used a three wire

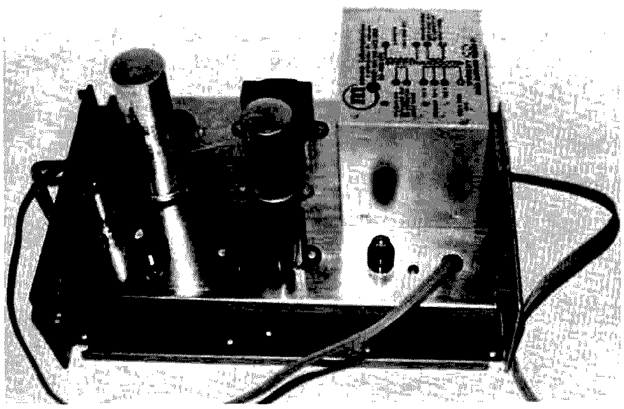

Fig. 1. The new power supply for the BC-779-B.

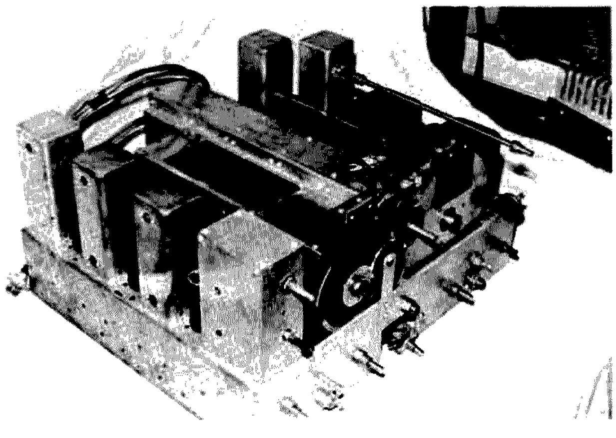

Fig. 2. "Old Faithful" with the front panel removed, ready for cleaning and repair.

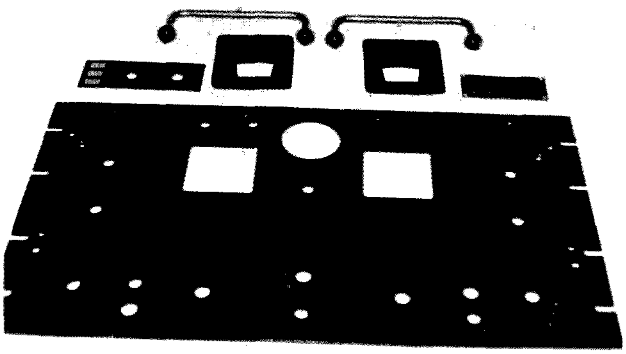

Fig. 3. Newly painted front panel with handles, escutcheons and name plate.

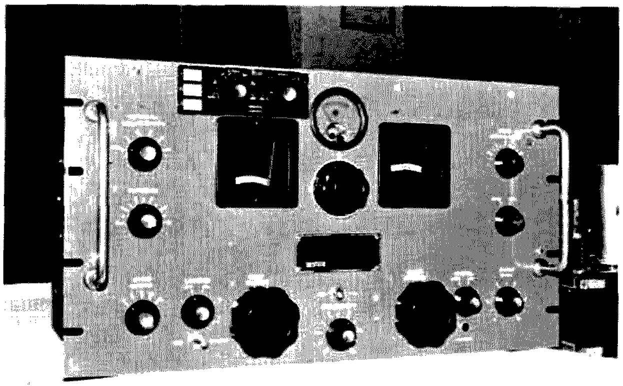

Fig. 4. The completed receiver.

line cord to complete the supply. Fig. 1 shows you how the new supply looks.

When I had the receiver working (no AVC yet, that would come later), I decided to remove the front panel and refinish it. Be careful so that you do not lose any parts. Use a plastic pan to keep track of all the hardware and other parts. If the dial markings are not etched into the panel, make a drawing of the panel and the location and names of all the controls. Fig. 2 shows the receiver after the front panel was removed. All of the panels I have worked with have been either steel or aluminum. The method of refurbishing that I will explain has worked well with both types of panels. First strip all the paint from the panel. Use a good quality liquid stripper. A pint should be sufficient. Read the directions carefully and heed all warnings. When the paint has been removed, it is a good idea to remove any grooves or burrs. Make the panel as smooth as possible. A primer is very important to getting a good final finish. Buy a good metal primer, close to the finish color of the panel. I have had good luck with auto primer. Use several light coats to prevent runs and bubbles. It is helpful to bake the primer. In winter, I put the panel on a ledge of my heating unit. If the cook in your home is rather liberal, you may be able to bake the panel in the oven at 200° for a few hours. If the first coat is not consistent, add a second coat. Be patient. Allow at least twenty-four hours in between coats of primer or finish. If you are like I am, you will have a tendency to want to get the painting done quickly to see some results ... resist the temptation! You will hate yourself in the morning if you don't. Now apply a coat of the finish color. Rub it out after twenty-four hours. I use an inexpensive auto rubbing compound. Use at least two or three coats of finish. This will give you more ability to rub out imperfections. You could use a spray paint color which is available at a paint or hardware store, or you could go custom by having a color mixed at an auto paint distributor. Fig. 3 shows the repainted front panel, escutcheons, name plate, and handles.

Congratulations! You now own a beautifully painted metal panel ready for lettering or decals. Easy now. This is your last chance to really guff-up your work of art. My panel was engraved, so all I had to do was work white tempera into the panel and let it dry. For my finishing touch, I paste-waxed the panel with Johnson's Paste Wax and lovingly buffed it until I was satisfied with the results.

Because of the weight of the receiver, and to add some aesthetic quality, I added six inch handles to the panel. The handles also make it possible to lay the receiver on its face for servicing. The escutcheons were sprayed flat black and a cracked plastic window was replaced with new plastic. The old knobs can be cleaned and small scratches removed by using rubbing compound and then paste-waxed them. New knobs, or knobs of more appropriate size, for tuning or bandspread may be added. I used larger knobs for the tuning functions. It gives the same effect as increasing bandspread. Fig. 4 indicates the modern appearance of the new paint and knobs on the thirty-five year old beauty.

Now is a good time to test the tubes and clean the chassis. I used clorethane for the chassis, along with a toothbrush and a smaller brush for all those tough corners. Some of the plated parts such as covers and chassis supports can be polished with SOS pads and then sprayed with a clear plastic such as Krylon's Crystal Clear. If there are any markings on the chassis, they should be renewed. Remark them now. If you put it off, you will never do it. Fig. 5 shows the cleaned chassis and new power supply.

After the refinished panel was again installed, it was time to complete the electrical repair. The AVC problem that I had mentioned earlier was due to a shorted capacitor in the screen circuit of the AVC amplifier. The short had opened a 2000 Ohms screen supply resistor. I felt it would be a good idea to replace all the thirty year old capacitors at this time, especially those used for bypassing and coupling. This was

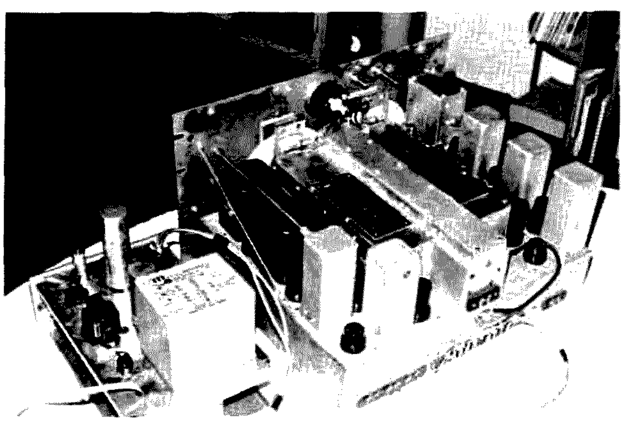

Fig. 5. Cleaned chassis, new power supply and interconnecting cables.

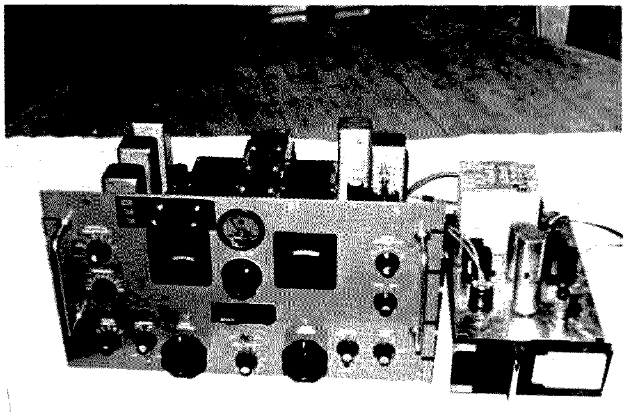

Fig. 6. The "gift receiver" recycled and ready to operate.

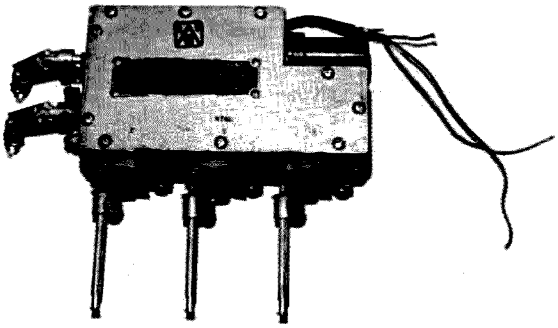

Fig. 7. The MC-531 crystal controlled oscillator modification kit.

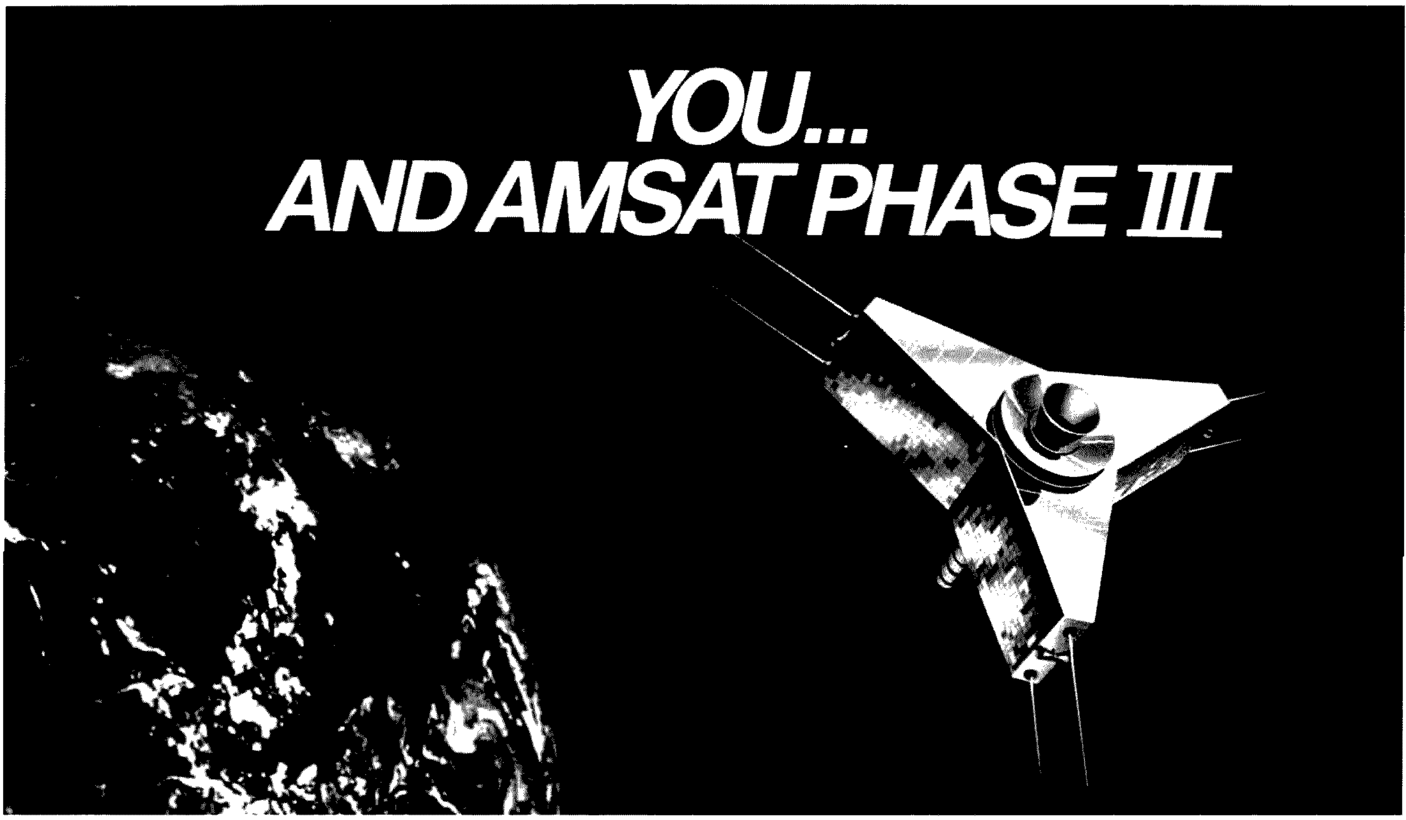
easily done because there is ample room under the chassis. I checked several resistors and found them to be well within tolerance, so I did not replace any resistors in this set. This was quite unusual, in my experience, because I have found that older pieces of electronic gear suffer from many resistors which have changed value well beyond 20 percent. I also replaced an AM-CW toggle switch with a rotary switch so that the front panel would be authentic and have the correct number of knobs and switches. Fig. 6 shows the completed receiver and power supply prior to installation in the station console. The last modification that I made to the receiver was the removal of an earlier modification. This was the MC-531 crystal oscillator which made the receiver capable of three additional crystal controlled frequencies like its newer brother, the SP-600 JX. My reason for doing this was the poor way in which the oscillator was tied into the receiver. It extended the receiver oscillator circuits and made them vulnerable to mechanical vibration and instability. The MC-531 plate and knobs were left on the front panel of the receiver to cover up the holes. Fig. 7 will give you an idea of what this unit looks like.

Before final alignment I decided to let the receiver run for long periods of time over a two week time span. This usually will cause weak components to fail and save a lot of trouble later on. During this time I got used to the controls and the operating characteristics of the old Super-Pro. The more I operated it, the more I enjoyed it. The removal of the MC-531 oscillator cured any doubts I had about the oscillator being stable enough to use on twenty meter SSB and the crystal selectivity impressed me when using it for CW. Believe it or not, there is a phono input which gives reasonable quality audio out of a pair of 6F6s. What more could a person ask for in the well-equipped ham shack?

Now let's get to the alignment. I borrowed the best signal generator I could find, another big, heavy surplus tube-type device, called the AN-TRM/1. I allowed both the generator and the receiver to warm up for several hours, along with the basement ham shack. I have never known such a cold winter! As with most quality receivers I have aligned, this one was a breeze. The manual was specific and complete. The i-fs were tuned with air padders, real class! The rf alignment went just as smoothly as the i-f and I was able to get a nice even response across each band from one end to the other. I calibrated the S meter according to the manual, 50 microvolts gives an S9 reading at 3.5 MHz. For a change, I have some idea what the S-meter reading really means. The alignment took an evening, which was an enjoyable way for me to spend that period of time. It was the culmination of a couple months of part time labor which had a happy ending. For me, there was a great deal of pride in recycling an old piece of electronic gear into a useful and pleasant surprise which should keep going for many more years.

So far there has only been one unusual quirk in the operation of "Old Faithful." Occasionally when I am listening to shortwave broadcasts late at night, I will hear strange sounds like the music of Glenn Miller and Benny Goodman floating ethereally through the speaker when I tune to a place near 20 MHz around the old haunts of WWV. ■



An exciting new era in amateur radio is about to begin... the era of AMSAT PHASE III OSCAR satellites.

Many of you are familiar with the benefits of the AMSAT OSCAR satellites, notably OSCAR 6 and 7. These satellites, with a combined total of over 8 years in orbit, have provided communications between amateurs throughout the world. They have also provided a capability for an educational program in space sciences and many interesting experiments.

AMSAT, with members and contributing groups worldwide, and headquarters in Washington, D.C., has been responsible for our current satellite program. Many people feel that perhaps the greatest value of the amateur satellite program is the dramatic demonstration of amateur resourcefulness and technical capability to radio spectrum policy makers around the world.

The value of this aspect of amateur radio as we prepare for the 1979 World Administrative Radio Conference (WARC) is enormous.

The AMSAT PHASE III satellite program promises a continuing demonstration that amateur radio is at the forefront of modern technology. PHASE III satellites will routinely provide reliable communications over paths of up to 11,000 miles (17,600 km) for 17 hours each day. You can think of them as a resource equivalent to a new band.

The cost of these PHASE III satellites is a projected $250,000. Commercial satellites of similar performance would cost nearly $10,000,000.

<u>Your help is needed to put these</u> PHASE III OSCAR satellites in orbit.

<u>Your</u> valued, tax-deductible contribution can be as small as one of the 5000+ solar cells needed. A handsome certificate will acknowledge the numbered cells you sponsor for $10 each. Larger components of the satellites may also be sponsored with contribution acknowledgements ranging to a plaque carrying your name aboard the satellites. Call or write us for the opportunities available.

<u>Your</u> membership in AMSAT is important to the satellite program, and will give AMSAT a stronger voice in regulatory matters concerned with satellites. At $10 per year or $100 for life, you will be making a most significant contribution to the satellite program and the future of amateur radio. You will also receive the quarterly AMSAT newsletter.

Clip the AMSAT PHASE III coupon below and send your support today, or call 202-488-8649 and charge your contribution to your BankAmericard (VISA) or Master Charge card.

The publisher has donated this space to AMSAT in support of AMSAT and the PHASE III program.

Build A Double Bazooka

-- give your signal a blast

William Vissers K4KI
1245 S. Orlando Ave.
Cocoa Beach FL 32931

An interesting fourteen page mathematical analysis of why the coaxial dipole antenna doesn't work for the average amateur appeared in the August 1976 issue of *Ham Radio.* I did a double take when I first read it. About a year ago, after having been off the air since 1935, I decided to get back on. My bright and new Yaesu FT-101-B worked fine, but a simple broadband antenna was needed for the 80 meter band. It seemed that a double bazooka, or coaxial dipole as it's also called, would be just the thing.

Before I built one, I did a bit of thinking as to just what made a double bazooka work. I realized that a very simple change would make it work a lot better than any of the ones previously described in the literature I had read. After reading the referenced article, I decided to repeat my previous experimental work and also delve a bit deeper into why my double bazooka worked so well when the theoretical analysis proved the coaxial dipole wouldn't work.

Being an old-time ham, ex-W3RN (1928), possessed of more low cunning than high math, I want to say that I won't write a long mathematical treatise as to why my antenna works as well as it does. The mathematics of the referenced article are absolutely correct, so anyone reading the referenced article can go to it and repeat any or all of the math he likes.

Instead of analyzing a theoretical thin wire dipole in free space, we'll analyze a dipole antenna that more closely represents the characteristics of one built by the average amateur. Then we'll add the coaxial stub sections and see what happens. At the same time we'll observe the improvement in lowering swr by using my new parallel connection technique as opposed to the series method previously used.

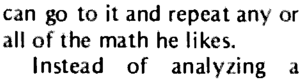

Fig. 1. Basic dipole antenna.

This analysis will be theoretically calculated and the resulting curves shown. The curves will show the antenna without any stubs connected, then with the series method, then with the parallel method just developed. And, finally, I'll show the same kind of curves as actually measured at my coax line feeding the antenna from the transmitter. This will allow each amateur to make his own decision as to whether a coaxial dipole has any reason for being.

But one of the most compelling reasons for not going through pages of math is quite practical. Most average hams like myself are more interested in seeing actual results. Besides, anyone can check the math for himself from the referenced article. And now, as an example, I'll pull some figures and values out of a hat in midair and show some results. Later I'll explain just why I chose the figures I did. This way we can show the results first and figure out the whys and whereofs later on. I guarantee it will be a lot easier that way. Lastly I'll add a few general comments when I compare a double bazooka to other antennas designed for broadband usage.

Some Basic Theory

First, to refresh our memories and see exactly what we are going to explain, let's think about a simple dipole antenna as shown in Fig. 1. It is a wire an electrical half wavelength long with an insulator in the center where our feedline will attach at points A and B. And we know that for practical purposes our antenna at resonance can be represented by the simple series circuit of Fig. 2. R_a is the antenna resistance. X_l is the inductive reactance, and X_c is the capacititive reactance in Ohms. Also at resonance, X_l is equal to X_c numerically, but of opposite sign. And so at resonance our impedance is simply R_a. The Q of the antenna is X_l/R_a. Z_c is the impedance of the feedline we will use, and for our purposes it will be 50 Ohms, as that's what is generally available and used by the average amateur. And also at resonance, the swr is Z_c/R_a when Z_c is larger than R_a, and the swr is R_a/Z_c when Z_c is smaller than R_a. And if we were really lucky and had an antenna with a resonant resistance of 50 Ohms, our swr would be simply R_a/R_c or 50/50 or 1:1, and you can't improve on that.

There is not only one fly in the ointment, but at least three big ones and a few smaller ones buzzing around, as I'm sure you have already guessed. First, our antenna resistance is not always 50 Ohms. It can be either higher or lower. Second, and more importantly, is what happens when we tune our transmitter

Fig. 2. Basic dipole antenna resonant at 3.75 MHz. Q = 10, swr = 1.25:1.

Fig. 3. Basic antenna dipole equivalent circuit at 3.5 MHz. Swr = 3.27:1.

to some frequency away from resonance. Then there is the third fly of basic antenna Q, which will have an important effect on how well our double bazooka antenna works.

But let's first stick with our basics a bit longer and see what happens, for example, when our antenna has a Q of 10 and a resonant resistance of 40 Ohms. We'll assume, and for practical purposes we won't be too far off, that our basic antenna dipole resistance will stay at 40 Ohms over the entire 80 meter band. Let's also assume our resonant frequency is in the middle of the band at 3.75 MHz. Our X_1 will numerically be equal to X_c and will be equal to X_1 = (Q) (R_a) = (10)(40) = 400 Ohms. And our swr at resonance will be Z_c/R_a = 50/40 = 1.25:1 at 3.75 MHz.

Now let's look and see what the antenna looks like at 3.5 MHz. Our inductive reactance will decrease to (400)(3.5 MHz)/(3.75 MHz) = 373.33 Ohms. Our capacitive reactance will increase to (400)(3.75 MHz)/3.5 MHz) = 428.57 Ohms. The difference will be 428.57 minus 373.33 which is equal to 55.24 Ohms. So at 3.5 MHz our antenna no longer looks like a pure resistance of 40 Ohms, but looks like a 40 Ohm resistance in series with a capacitive reactance of 55.24 Ohms, as shown in Fig. 3. And the calculations for the swr of our antenna at 3.5 MHz with the 50 Ohm coax feeder tied on turns out to be 3.27:1. As I mentioned earlier, the basic mathematics of the referenced article go into the details of how to calculate swr, and, as we didn't want to make this article too mathematical, we'll let it go at that. However, I'll do some more math calculations myself and just show the curves. It will save us all a lot of time and effort.

Well now that we've seen that our basic dipole has an swr of 3.27:1 at 3.5 MHz, we wonder if there is any way that we can reduce the swr to a lower value. Here is where the double bazooka comes in.

But before going directly to the antenna, let's see just what we are actually going to do. If we look at the characteristics of a parallel resonant circuit and compare it to the series circuit of our basic dipole, we will find some interesting things. Let us just arbitrarily take a condenser of 3600 pF and an inductance of .5 uH and connect them as a parallel circuit. It just happens that this circuit will resonate at 3.75 MHz. If we assume a perfect coil and condenser, the parallel impedance at resonance will be infinity. So if we were to place this parallel resonant circuit across the insulator of our basic dipole, nothing would happen at a frequency of 3.75 MHz.

But what happens to our parallel circuit by itself if we tune the transmitter to 3.5 MHz? With a bit of basic circuit theory, we find the parallel tuned circuit will be equivalent to an inductive reactance of 85.3 Ohms. And we already know that our antenna by itself at 3.5 MHz showed a capacitive reactance of 55.24 Ohms in addition to its resistance value of 40 Ohms. This tells us that when we look at Figs. 4 and 5, that the inductive reactance of the tuned parallel circuit at 3.5 MHz could be used in some manner to cancel all or part of the capacitive reactance of the antenna at this frequency.

Another interesting thing is that the equivalent antenna resistance will no longer look like 40 Ohms but will be at some higher value. Fig. 5 shows the total equivalent circuit impedance of the combined system. The equivalent resistance is now 116 Ohms and the capacitive reactance has dropped to the extremely low figure of 2 Ohms. So we have seen that by picking the right kind of parallel tuned circuit, we can practically eliminate the reactive component at the band edge of 3.5 MHz.

A similar action would take place if we left things as they were and tuned the transmitter to 4 MHz. And now if we were to calculate the swr of the combined circuit at 3.5 MHz, shown in Fig. 5, we would find that the swr has been reduced to a value of 2.33:1. And, as our original swr without compensation was 3.27:1, we see that there is a way to reduce swr in an antenna.

It might be reasonably asked at this point, if we can theoretically reduce the swr of an antenna system with a simple parallel resonant circuit, why go to the double bazooka system? There are two basic reasons. First, we notice that the value of capacity required is very high and that the inductance is only .5 uH. To properly tune and build such a network tuned exactly to 3.75 MHz and install it across your antenna insulator would be quite a job. Second, it would be hard to build such a system using practical components and still obtain a high Q. Since we want the Q of the parallel circuit to be as high as possible for best results, this means we want the losses to be as low as possible.

Fortunately, a shorted quarter wavelength of coaxial cable will act like a high Q parallel tuned circuit. At the same time, the quarter wave sections will also act like a portion of the antenna radiating system. As a matter of passing interest, as it does have some bearing on our further discussion, we could in this example replace our parallel tuned circuit with a quarter wave piece of coaxial cable cut for 3.75 MHz. However, this piece of cable would have to have a characteristic impedance of nine Ohms. To my knowledge, there is no such kind of coaxial cable of this low impedance on the market available to the average amateur.

We know that our antenna will have two quarter wavelength stubs, one on each side of the center insulator. If we plan to use 50 Ohm coaxial cable, we can readily see that if we were to parallel the two stubs, we would get down to 25 Ohms. However, the double bazooka antennas used up to this time have all showed the two stubs connected a series, which gives a characteristic impedance of 100 Ohms. And we know that 25 Ohms is a lot closer to 9 Ohms than the

Fig. 4. Parallel tuned circuit.

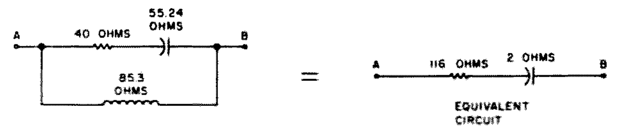

Fig. 5. Basic dipole antenna with parallel tuned circuit connected in at 3.5 MHz.

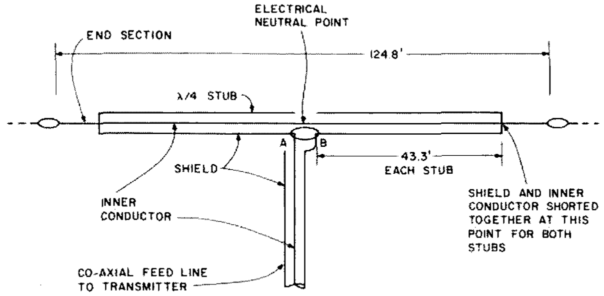

Fig. 6. Coaxial dipole series connected.

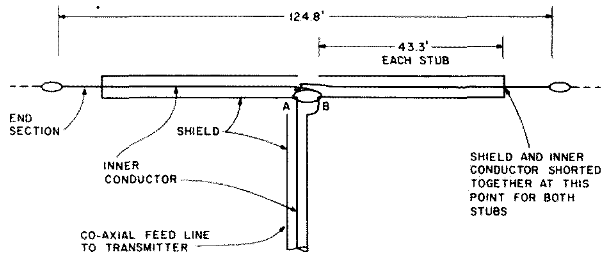

Fig. 7. Coaxial dipole parallel connected.

previously used series connection of 100 Ohms. The stub improvement ratio is a factor of four to one, which is nothing to be sneezed at in any antenna system. So if anyone already has a series double bazooka antenna up, all he has to do is to change over to the new parallel configuration and notice the marked reduction in swr. The series and parallel stub configurations are shown in Figs. 6 and 7.

The original coaxial stub antenna was designed by the staff of MIT for radar use. Their design shows a series stub system. Actually when you start from an original design and are not limited like we are to the use of 50 Ohm coaxial cable for feedline and stubs, the antenna system could be optimized using either a series or a parallel stub system. Naturally the feedline and stub impedances would be different for the two different types of antennas.

The series stub system was apparently used for a very good and simple practical reason. In the series stub system, there is an electrical neutral point where the center conductors of the coaxial stubs join, while the parallel stub system does not have such an electrical neutral. And the electrically neutral point of the series system was used as a mechanical support point. In this way the radar antenna could be easily mechanically physically supported without an expensive electrical insulating system being required. One would have been needed if the parallel stub method had been used.

Apparently, whoever first adopted the concept of a double stub antenna for amateur use just went ahead using the series stub connection without realizing that a parallel stub system is quite superior when using 50 Ohm coaxial line. But that's why I can't help but feel that basic concepts are sometimes better than high mathematics where you can easily lose sight of the basic objective which, to me, is to build an antenna with the lowest possible swr. And that's what this article is really all about.

Antenna Characteristics

Although we mentioned that the referenced theoretical mathematical analysis of a thin wire in free space was correct, there are a few things that should be further considered. There is no disagreement that the free space thin wire coaxial dipole will not work well in the series configuration using a 50 Ohm feedline and 50 Ohm stubs. But, and this is a very big but, the average antenna put up by the average amateur differs markedly from an antenna in free space. An analysis of a coaxial dipole using thin wire implies that there is such a thing as thin wire coaxial cable to be used for the stubs. There is no such thing. The very fact that coaxial cable has a finite thickness would lower the Q of the free space thin wire antenna. And we will find that the lower the Q, the better the stub sections will work.

But more important than the previous technical point is that the resonant resistance of an average amateur antenna is considerably lower than that of an antenna in free space. For a horizontal antenna to have a resistance of 73 Ohms, which is the same as free space resistance, the antenna height has to be at least a quarter wavelength high. And this, for our resonant frequency of 3.75 MHz, turns out to be 65.5 feet high. And in all honesty, how many average amateurs can boast of a pair of poles that high supporting a horizontal antenna 125 feet long? There are none in my acquaintance. Usually our average amateur is lucky if he can get up an inverted V with the center pole about 35 to 40 feet above the ground, with the ends sloping downward. Antenna resistance drops rapidly as the antenna height is decreased. Also, when an antenna is formed into a V, the resonant resistance decreases. Combining these factors and actual antenna resistance measurements, I have found that a good conservative value of antenna resistance will work out to be about 40 Ohms. And that, oddly enough, is the value we have used in our basic dipole calculations. This value is opposed to the theoretical free space value of 73 Ohms. And that is a big difference.

The other important factor is actual antenna Q. An antenna in free space does not have any losses except its radiation to free space, if we want to term it as such. Thus for a theoretical thin wire, its Q is high. However, for an antenna nearer the ground, there are a number of additional but unavoidable losses. These losses are ground losses, losses due to local buildings and bushes, and actual losses in the antenna system itself. My own measurements on amateur antenna systems have confirmed that such combined losses will have a marked effect on reducing the basic antenna Q. And after much thought, a Q value of 10 was chosen. And, as we mentioned earlier, a low Q of our basic antenna system will make the stubs relatively more effective. This fact has been known for some time in the construction of coaxial dipole antennas. Some amateurs even make the end sections of their coaxial dipoles out of open wire transmission line to reduce the Q. A very good example of this is shown in the 1975 ARRL *Amateur Handbook* in the description of a broadband dipole popularized by W8TV. He used open wire line for his end sections, and reported measured values of swr of 1.7:1 at 3.5 MHz and 1.9:1 at 4.0 MHz. But every amateur will have to make his own trade-offs in determining just how he wants to build his own antenna. In my case, I didn't use any open wire line for the end sections, but just extended the coaxial cable. And my own measured swr was a bit higher than obtained by W8TV.

Theoretical and Actual Measured Swr Curves

In the final analysis of any theoretical calculation, the best proof is correlating experimental data. The curves of Fig. 8 are the theoretical calculations of swr based upon an antenna that we had

assumed approached the characteristics of that put up by the average amateur. Curve A is the antenna without any stubs connected. Curve B is the same antenna with the quarter wave 50 Ohm stubs connected in series. And lastly, curve C shows what happens when the stubs are connected in parallel. It is very obvious that the parallel stub system is quite superior to that of the series connected system. And, as we had previously indicated, these calculations did not take into account feedline losses.

Fig. 9 is the proof of the pudding. The curve nomenclature is the same as Fig. 8. These measurements were made directly at the transmitter using two four inch Swan WM-1500 wattmeters capable of reading forward and reverse power. The meter accuracy is 10 percent at full scale. Swr calculations were made from the forward and reverse power measured. It was interesting to note that the actual measured data showed a better swr improvement than what the theoretical calculations had predicted. But the measured data clearly shows that a broadband coaxial dipole is an actual reality and not a mathematical impossibility. My own advice is, "Try one, you'll like it."

Final Observations

The final question that should be thought of is, are there any better simple broadband antennas for 80 meters than the coaxial dipole? In my personal knowledge, I don't know of any. The writer of the referenced article mentions such things as a multiwire fan shaped bow tie dipole invented by P.S. Carter of RCA and used since 1937 to obtain the bandwidth necessary for television. This is correct, but when we magnify such an antenna to the proportions needed for an 80 meter antenna, I would suspect that just the mechanical construction would be a bit formidable. He also mentions the work done by Dwight Borton W9VMQ titled, "80 Meter Bow Tie Antenna," *Ham Radio,* May, 1975. This is an extremely interesting article to read. However, from the curves shown by W9VMQ, the double bazooka antenna shows a lower swr than a bow tie antenna made of regular copper wire. It is only when the bow tie antenna was constructed out of galvanized wire, rather than regular copper wire, that the swr of the bow tie was lower than that of the coaxial dipole. Unfortunately, this fact was not brought out by the writer of the first referenced article. It should be quite apparent that the swr of any antenna system can be lowered by using wire with a higher electrical resistance than regular copper wire. But why intentionally introduce losses that are not necessary? That's a trade-off that every amateur will have to decide for himself. My final advice is to "keep your bazookas up and your swr down!"

Antenna Length Calculations

The following information is used in calculating the lengths of the stubs and also the overall length of the antenna. Calculations are shown for an antenna that is resonant at 3.75 MHz. All dimensions are in feet.

$$\text{Stub length} = \frac{(246)(\text{Velocity factor of coaxial cable})}{\text{Frequency in MHz}}$$

And, assuming we use RG-58/A, we look up in the antenna handbook and find it has a velocity factor of .66.

$$\text{Length of each stub} = \frac{(246)(.66)}{3.75} = 43.3 \text{ feet}$$

The antenna overall length is calculated using the equation:

$$\text{Length} = \frac{468}{\text{Frequency in MHz}}$$

$$= \frac{468}{3.75} = 124.8 \text{ feet.}$$

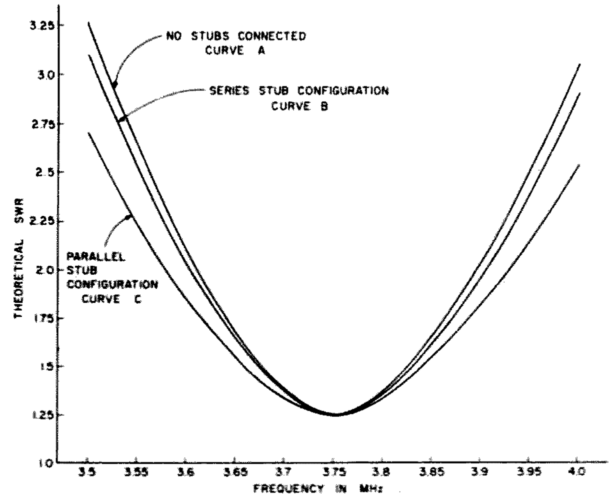

Fig. 8. Theoretical calculations for dipole antenna. R_A = 40 Ohms, Q = 10, resonant frequency at 3.75 MHz.

If it is desired to make experimental measurements to see what the swr of your antenna is without the stubs connected, it can easily be done as follows. Just connect the center conductor of each coaxial stub to its own shield. Leave the feeder connections as they were.

In Figs. 6 and 7 I've shown the feeder line of coax cable connected directly to the antenna without the use of a balun. My own antenna seems to work fine without a bulun, although a balun may make your antenna more electrically balanced.

It may be necessary to trim and adjust the overall length of the antenna to compensate for end effects and the presence of nearby objects. In my own case, I notice measurable changes in both antenna resonant frequency and swr when I even trim the hedge near the ends of my inverted V coaxial dipole. The ends are about twelve feet above the ground.

And, as previously mentioned, if you use something like an open wire line for your end sections, you will probably further reduce your overall Q and your band edge swr values. The swr you get is a function of several variables, and you'll find that experimentation is both fun and truly instructive, as it has been in my own case. ■

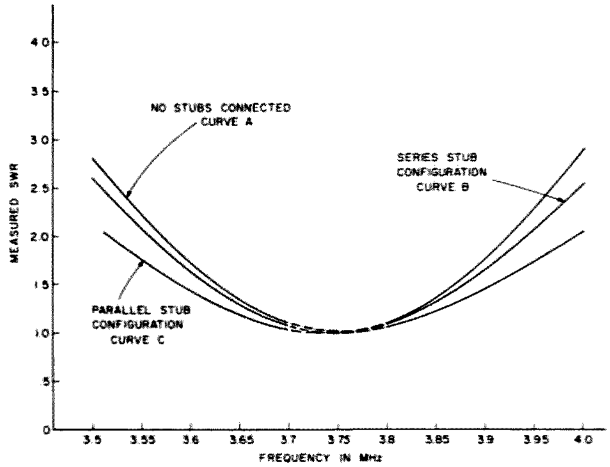

Fig. 9. Actual measured values of swr for inverted V coaxial dipole.

Dirt Cheap Directional Array

-- for the serious DX hound

Daniel P. Shaver WA4BKQ
7523 Todd Pl.
Manassas VA 22110

In my endeavors to achieve a halfway decent and readable signal for some rare DX station to pick me out of a pileup of California kilowatts and TH6s, I contemplated running up a $1000 bill and installing an antenna system that would give me armchair QSOs with FB8s. Other things made my early ham life as a two-bit DXer difficult and embarrassing: I am a high school student, and I have little spare cash. When I first joined PVRC, I was using a DX-60B and a vertical antenna ("What's your setup, Dan? . . ." "Well, uh . . ."). Finally, most hams would probably consider my ideas discrete at best. I thought I had a GOOD idea, though.

Well, all you other 16 year old hams who are cheap, lazy (but zealous), and with Extra class licenses but Novice minds, here's an antenna system that should cost you about one-tenth of the abovementioned price – that's including a 40 ft. self-supporting structure, antenna, and all the other junk you're going to need on the way. (Of course, this construction article is no different from the rest, so I might add here that you should adjust this liberal figure to about 1.3-1.5 times the abovementioned price if you are a conservative.)

The supporting structure (a complicated name for a utility pole) is of primary importance. I managed to give the guy down at the local electric company a combination sob story and snow job resulting in a 42 foot pole (used, of course) at 25¢ per foot. Yep, that's $10.50 for a self-supporting tower. Great, huh? With a little bit of luck, one should be able to swindle a used jobby from a local utility company for less than twice that price.

I then simply gave a construction contractor a call and had the pole installed in my backyard for $35. This was also a fervid attempt to get my money's worth. Most anyone should be able to do the same for only a few bucks more. (Optimistic, aren't I?) The gigantic tarred dowel was sunk into the ground about six feet; however, considering that my father didn't feel like having a sunlight in his roof on windy days, I made sure the pole would not decide to fall. The foreman assured me it would not . . . Whew! My parents now consider the pole an eyesore, my neighbors consider it an attraction, I consider it a status symbol, and my fellow hams consider me an idiot.

As for the antenna . . . beams are way too expensive, and a vertical would be downright stupid; I therefore decided on a quad. I managed to find a really good deal on a two element boomless – William's Antenna Company* sells a complete tri-band quad kit with everything (bracket, copperweld, insulators, gamma matches, clamps, etc.) except the bamboo spreaders for $25. It's a darn good deal.

The bamboo can be obtained by two methods. One is by going down to your friendly carpet dealer and picking up any surplus he has lying around, or one can go a la naturale as I did. I drove through a neighboring town last fall and found a whole patch full of strong, 15-20 foot high bamboo stalks. I knocked on the fellow's door, and within twenty minutes I had 15 nice straight, immaculate poles. The city slicker or northerner might find this method of obtaining bamboo spreaders difficult; on the other hand, this method is easy and practicable for those throughout the South. Bamboo is a grass and therefore sprouts quickly. If need be, you can even grow it in a wet place near your home. I don't, however, suggest this method for the supporting structure unless you have great patience. The bamboo is simply given two coats of good enamel paint, and they're ready to go.

Instructions in the WAC quad kit are extremely simple to follow, almost like Heathkit. Depending on what you want, though, one may decide to up the cost and buy a quad or beam or even down the cost by building one. I obviously preferred the compromise route and am thoroughly pleased.

Tuning comes next. I found that the easiest way of tuning the gamma matches on my quad was to mount it on a regular TV type bracket at a height of 10-12 feet up the side of the utility pole. This allows the stubs to be reached from ground level. (You ten meter buffs will probably have to use a ladder, but the effort is still a lot less than hanging off the side of the tower.) Remember that the resonant frequency of the antenna will rise three to five kHz for every foot the radiator is erected above ground, so tune your center frequency accordingly.

One feedline is all that is necessary if one uses the gamma match system. A tolerable swr can be obtained with direct feed, but cropping the wires is introduced. (This is more difficult than it seems, since there is quite a bit of tension introduced by the spreaders on the wires.) With either method, a suitable swr can be tuned in using a bridge in line at the input of the antenna. Another advantage of the quad, by the way, is that it is very broad banded and when tuned correctly, an swr of less than 1.9:1 can be expected plus or minus 250 kHz from a center frequency.

*404 Sanders Rd., S.W., Huntsville, Alabama 35802.

Finally, the hard part comes ... getting that 2500 cubic foot thing on top of that pole. Well, there's some good news and some bad news. First the good: The quad, especially if made out of bamboo, is a lot lighter than you might expect. The utility pole approach provides a strong and steadfast structure that will support the heaviest of hams. With a man on the ground and a man near the top, the antenna can be hoisted to its apogee with a simple pulley or gin pole arrangement. Now for the bad news: Climbing a wooden pole is more easily said than done. By all means, watch your step if you decide to use hooks. I, for one, though, prefer having the steel spike type steps on the tower. They make climbing easier and more sure. Don't make the mistake I did: Have those steps bolted in *before* the pole goes up; putting them in after is not impossible, but is considerably more difficult. Either way, always use a safety belt!

At last, the antenna is erected. A TV chimney mount was used in this case along with small wooden blocks (Fig. 1). A pipe or short mast is bolted to the mount so that 12-18 inches protrude from the top of the pole ... and the rotor's connected to the pipe, and the antenna's connected to the rotor.

All that's needed now is to run your coaxial lines and rotor cable to your shack. By the way, an el cheapo used TV type rotator will suffice for the quad. I must emphasize again that the weight of the antenna is extremely small. (Just don't put a 20 foot mast on the antenna ... keep the length of the mast between the quad bracket and the rotator as short as possible.)

Of course, there are many variations to this antenna scheme (e.g., a beam instead of a quad), but if the preceding information is closely followed, the whole thing can be built and erected for less than or around $100. Let's recap what has been spent...

Utility Pole	$10.50
Installation	35.00
Quad	25.00
Rotator (used)	15.00
Coax and Cables	11.00
Mounting Bracket	2.75
TOTAL	$99.25

Not bad for a truly *complete* 20-15-10 meter, 7 dB, rotatable antenna system, eh? If the price backfires, you can use this article at least for some ideas.

Performance

Even when the quad was on the ground for tuning, it exhibited exceptional gain. I made many first shot QSOs with several Soviet and European hams with mostly 58-59 plus signal reports. My rig is a barefoot HW-101, so I'm not using anything extravagant. The whole system really amazes me, and I'm sure it will amaze those who decide to try it.

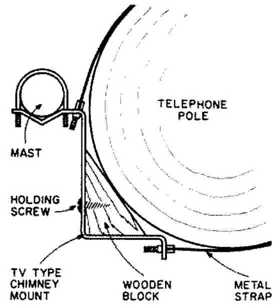

Fig. 1.

So there you have it, cheap, conniving, fervid hams of all ages. You won't be an armchair DXer right away, but give yourself some time (and the antenna a chance). Even dirt cheap directivity makes all the difference in the world. Good luck (you'll need it), and I'd be interested in hearing how your antenna party goes.

Special thanks go to WB4DHW who helped materialize the initial part of the project, to WB4TBO and W4WRJ for their technical assistance, and to my family for putting up with me. ■

Instant PS Regulation

-- a quickie

Need an additional regulated supply in a hurry, perhaps to finish up some project which requires a special voltage, or perhaps the regular supply is just overloaded? If you have a source of dc voltage higher than the voltage you need, you can make the regulator by adding only two components, a transistor and a battery. The circuit is shown in Fig. 1 for both positive and negative output supplies. As you see, the battery supplies base current to the pass transistor, which acts as a variable dropping resistor. The battery drain is equal to the current supplied divided by the transistor gain. The output voltage is equal to the battery voltage minus the base-emitter drop.

If closer control of the output voltage is needed, it can be obtained by adding series diodes as shown in Fig. 2. Also, if better regulation is needed, it can be obtained by using a pair of transistors in the Darlington connection, as shown in Fig. 3. This connection is also worthwhile if the supply is to be operated for any length of time, since the battery drain becomes very small.

Suitable sources for the unregulated voltage are a battery charger, a car battery, or an old filament or bell transformer with a series rectifier. In many cases, the charger or transformer-rectifier does not even need a shunt capacitor to reduce ripple. ■

Take Cover!

-- how to prevent antenna wind damage

I had worked for five years gathering the parts for my antenna system, and two years ago I finally got it in the air. It withstood winds of 70 miles per hour last summer. But then, with winds the weather bureau said were gusting to only 45 miles per hour, the antenna system came down.

The tower was 60 feet of Rohn 25G mounted by four 3/8" stainless steel bolts to the Rohn tilt-over base plate. This hinged base plate was fastened with two bolts forming the hinge. The other two held the plate from unwanted hinging, or, one might say, they held the hinge-plate from opening away from the base plate. The base plate was fastened to a four foot by four foot by five foot deep concrete block with ½" steel bolts. The tower was guyed at the thirty foot and forty foot levels with 1/8" stranded steel wire, plus additional 1/8" steel guys to the ends of two 10 foot side mounted arms. One side arm carried a TV antenna and the other a Hy-Gain Model 341 two meter beam.

The Ham-M rotator was mounted inside the tower at the 50 foot level, with a 1½" galvanized pipe mast extending through the top section bearing. Extending upward from this mast was a 10 foot mast with a Ringo-Ranger two meter vertical antenna on top. The TA-33 triband beam was mounted just above the top of the tower. At the 40 foot level on the tower was attached an inverted vee dipole of aluminum coated steel wire for 80 meters. This inverted vee was used as part of the guying system. Just above this antenna was a 19" side arm with a two meter 19" spike ground plane antenna used with my scanner.

The top set of guys on one side was attached to the chimney at about 45° from the tower. The other two guys went to screw type ground anchors, also at 45° from the vertical. The three sets of guys were spaced equidistant around the tower (120° from one another). All guys were broken into appropriate segments with egg insulators. Each segment of guy wire was secured by making two half hitches and then a tight wrap for 3-4 inches, with the loose end secured to the guy with a cable clamp.

The system was theoretically designed for 100 mile per hour winds. However, plans were that, if winds in excess of 60 miles per hour were predicted, the tower and antenna assembly could be lowered to ground level with a block and tackle mechanism attached at the thirty and fifty foot levels with a bow of ¼" aluminum and steel wire.

In designing the antenna system I had to keep in mind two major environmental factors: 1) We are close to the Gulf of Mexico (about 13 miles) and we get considerable salt in the air, which makes the air quite corrosive; and 2) this part of the Texas gulf coast is subject to hurricanes.

The postmortem examination of the antenna system suggested, but did not establish beyond a shadow of a doubt, several possible causes for the system to fail.

Several amateurs viewing the twisted wreckage were of the opinion that only a tornado, or similar twister, could have done the damage. They speculate that the twister came low enough to strike the top of the tower, but not the house. An alternative explanation was the harmonic effect of repeated gusts of wind, each amplifying the effects of the previous gust. No one thought a straight wind could have caused the damage.

This raises a question of wind effects we do not usually consider when designing an antenna system, namely the reinforcement of wind pressure by harmonic gusts. Similarly, reflections of a blast wave, if reflected in the proper phase, can at least double the effect of the blast. You may recall a few years ago a suspension bridge in the Northwest succumbed to the effects of harmonic vibration of the wind.

Observation number one: *When designing an antenna system, consider both straight winds and harmonic vibration, and design the guying system to prevent or dampen harmonic vibration.*

This can be done by proper attention to guying and control of any side arms on the tower to prevent the wind from catching the side arms and starting them vibrating.

On a guyed tower, the use of three guys at each level, each guy at 120° points on the tower with the guy running to a ground anchor (distant from the base of the tower equal to 60 to 80 percent of the height of the tower), is more stable than the use of four guys at each level. The levels at which a tower is guyed depend upon the height of the tower and whether or not a house-bracket is used. I prefer to place the first set of guys at twenty feet above the ground or twenty feet above the house bracket, whichever is higher. Some amateurs prefer the first set of guys to be at the 30 foot level. The second and subsequent sets of guys should be placed at twenty foot intervals.

What type of guy wire should be used? In the past I have used nylon rope, sisal rope, glass rope, and 1/8" and ¼" stranded steel wire. In our area, the various ropes, including glass, are rapidly destroyed by the effect of the sun and the salt air. I have used these ropes as halyards for longwire and dipole antennas and find the rope disintegrates in two years or less. Also one must consider stretch when using ropes. Nylon is particularly bad in this respect.

Steel wire corrodes rapidly in the coastal area, particularly where two dissimilar metals join (corrosion due to electrolytic effect). I have found plastic coated stranded steel to last longer and to be more effective than other guy wires. However, although 1/8" stranded steel wire may hold telescoping masts, or hold towers in other areas of the country, the lesson I have now learned is to not trust anything less than 3/16" to ¼" noncorrosive steel wires in the Texas gulf coast.

What about aluminum wire or copper coated steel wire? Aluminum is too soft, stretches and breaks easily. Copper coated steel may be satisfactory, but I have had no experience with it and therefore cannot recommend it.

Observation number two: *Fastening of guy wires should not be sharply kinked nor pull out easily.*

A double set of properly applied cable clamps would be the most desirable method of securing guy wires. Second choice would be to take 10-12 tight wraps of the free end around the guy and then clamp the remaining free end. There should be no sharp bends in the guy wire where any strain is applied. If you get a kink in your guy wire, don't put that section up. Cut it at the site of the kink and splice with an egg insulator.

Any side arms stretching more than three feet from the tower should be separately guyed from the end of the arm in at least two opposite directions.

Observation number three: *Prevent the tower from twisting due to wind or torque of the rotator.*

Several rotators have a braking action that applies considerable torque to the tower when they stop a rotating beam. A number of years ago the idea was proposed of using a heavy spring in the mast between the rotator and the beam. This heavy spring absorbs the torque. (I apologize to the author of the idea, as I do not remember his name nor the journal in which the article appeared.) Caution should be shown in selection of the spring; it cannot be too limber nor too heavy.

A method for preventing twist in a tower uses two guys to each point of the top level of guys and separates the top end of each set of two guys by about one to two feet with an angle iron or similar strong brace. Each end of the brace should extend beyond the edge of the tower by at least six inches. A guy is fastened to each end of the brace.

Observation number four: *Do not use dissimilar metals in contact that are exposed to the effects of moist air or rain.*

I have observed that even when protected by RTV or other sealant, dissimilar metals will corrode quite rapidly. This is particularly true of coax connectors.

One way to eliminate this corrosion is to thoroughly clean both coaxial connectors and then apply silicone grease to keep out the water. (Make sure that the electrical contact is not broken by the grease.) Wrap the connection with electrical tape and spray the tape with acrylic. Cover this joint with stretchable rubber tape and cover the rubber tape with another layer of electrical tape. (The rubber tape, when applied, should be stretched to about ½ its resting width.) Again spray the electrical tape with acrylic and cover the whole joint with RTV.

Of course, there are some junctions where this method cannot be used. On these, do the best you can with alternating layers of electrical and rubber tape (as above) and coat the whole thing with generous amounts of a compound like RTV.

Where joints cannot be adequately weatherproofed such as mast clamps and tower bolts, use weatherproof hardware, and stay away from dissimilar metals.

Observation number five: *Torque and shear pressures can be tremendous at hinges and other areas where a short and long arm around a fulcrum are involved.*

I was unable to measure shear pressures on the tower, but did calculate that when the tower was lying over at a 45° angle that there were at least ten tons of pressure at the end of the hinge plate. When my tower went over, it bent the base plate and two of the ½" steel bolts holding the plate to the concrete block. It also stretched and sheared two of the 3/8" stainless steel bolts, cracked three welds (two on the hinge plate and one on the base plate) and broke one of the tower stubs which had been welded to the hinge plate.

Observation number six: *Design your tower and antenna system to fall away from the house and power lines.*

I was successful in this part of the design. The tower, in falling, fell away from the house and power lines, striking and destroying only one small tree on the way down.

When placing your tower, be sure that it is more than the height of the tower from the nearest property line or electric power lines. The guys should be placed so that if a set of guys on one side breaks, the other two sets will pull the tower away from the house or power lines.

Observation number seven: *Read your insurance policy carefully.*

When I put up the antenna system, I had a special rider put into my homeowner's policy. Since I had over $500 in the system, I thought I insured it totally with a $100 deductible policy. After the tower fell, I contacted my insurance agency and found to my surprise it was not a $100 deductible, but a $100 maximum that the agent had written.

What can be salvaged from such twisted wreckage? It was surprising to us how much we could salvage in various innovative ways. The TA-33 looked like a pretzel, and one of the traps was broken internally. It appeared that most of the twisting of the aluminum elements was the result of the wind rather than the fall. Except for the aluminum support of the driven element, five of the six traps, and a couple of tip elements, I was unable to salvage any of the beam. However, it will probably be less expensive to replace the aluminum elements and the one trap, than to buy an entire new beam.

The two meter beam had three broken insulators, all elements bent and a bent boom. This aluminum can probably be straightened, and with three new insulators will probably work as well as new. The TV antenna sheared two bolts, but otherwise appears unharmed.

At first I thought I could salvage only four sections of tower and thus have only forty feet of tower. But here is where innovation came in. The 40'-50' section of tower was broken one foot from the lower end, and the mounting stubs on the base were broken. I cut off the broken end of the tower section and the stubs from the base plate, straightened the base plate and welded the shortened section of tower to the base hinge plate. A second section of tower was only bent and can probably be straightened, but I am not sure I would trust it. if this can be accomplished, I anticipate I will lose only about three feet of tower.

I hope that this recitation of my problems with this antenna system will help other hams to design and add more safety features to their antenna systems. I have not covered safety points such as wind loading, climbing towers, and others covered in the ARRL publications and the series of articles in *73*. I would encourage you to read them before you next erect a tower or antenna system. ■

Introducing the Intenna

-- new concept for mobile ops

The Intenna, produced by Microwave Filter Company, Inc. (6743 Kinne St., E. Syracuse NY 13057), uses the old principle of a coaxially fed slot in a metal groundplane. While the concept is not new, the application of this principle to low band communications is almost revolutionary.

Figs. 1 through 4 show the evolution of the Intenna from theory to practice. The distortion introduced by the shape of the auto body does not adversely affect the performance of the antenna. On the contrary, such distortion makes the antenna effective in the directions most favored by motorists – fore and aft.

The Intenna is quite directional. The major lobes of radiation are obvious when a vehicle equipped with an Intenna and a CB or 10 meter unit is turned in a circle while receiving a base station or other fixed transmitter. When the sides of the vehicle are toward the other station, the received (or transmitted) signals fall off sharply. Continuing the turn until the front or rear of the vehicle is aimed at the fixed station causes a dramatic increase in signal strength. As mentioned previously, this characteristic of the Intenna is hardly a disadvantage for most motorists. The vehicles behind or ahead of the operator are usually the ones that he is most concerned with.

Fig. 1.

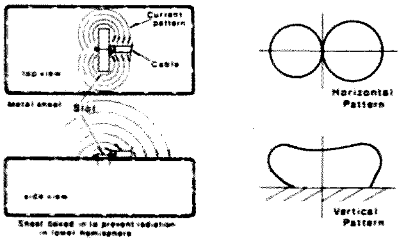

Fig. 2.

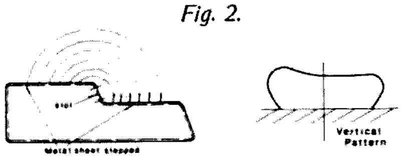

Fig. 3.

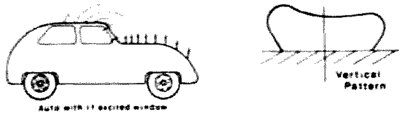

Fig. 4.

When I first heard about the Intenna, I said that there was no way that any antenna only 24 inches long could work as well as the flyer said that it could. My fellow workers agreed with me, but just for fun we decided to try one.

When I contacted Microwave Filter and expressed a skeptical interest, Glyn Bostick, President of Microwave Filter Co., promptly sent me two for evaluation. Even after seeing the Intenna and reading the poop sheet, I still didn't think that it could work any better than, say, a "shorty" gutter mount antenna. Boy, was I surprised!

It took me about an hour to install the Intenna. My 1973 Buick had no metal on the dash at the bottom of the windshield – the end of the wire which makes up the Intenna must be well-grounded if it is to work.

However, that was a detail which had been anticipated by the manufacturer. Included in the kit is a pointed brass rod with an eyelet on one end. I followed the instructions and pushed the rod through the rubber seal at the bottom of the windshield and, lo and behold, I had easy access to the rod on the outside of the car (just under the edge of the hood).

I trimmed the wire which comes down the windshield from the tiny tuner (which mounts at the top of the windshield under one of the screws fastening the inside molding to the body), and attached it to the rod as per instructions. As soon as I was certain that both ends were properly grounded, I connected the 8-foot piece of coax supplied with the kit to the tuner.

Also included in the kit are four self-sticking cable clips. These make it simple to route the coax around the inner windshield molding to the radio itself.

Now, according to the instructions, I was ready to begin tuning the tuner box for minimum vswr. Here was where I ran into trouble for the first time. I simply could not make the tuner do its thing. After running carefully through the instructions several times, I decided to call the factory and see what might be wrong.

On the front cover of the dealer package sent to us is a number to call collect – that's right, collect – if problems are encountered with tuning. When I called at about noon on a Saturday, I was given an "800" number (inward WATS) to call. The technician who came on the line was quite courteous and sincerely interested in helping. He asked me a few questions, offered a few suggestions, and told me to call him back and let him know how I came out. He also told me that if I couldn't get it working, he would try to arrange to come down and tune it himself.

When I asked whether I was being put on or not about him traveling over 1000 miles to tune an antenna, he assured me that his job was doing just that. I later talked with Glyn Bostick

about this. Glyn told me that he was doing whatever was necessary to see that all Intenna customers were happy. He said that he felt that early adverse publicity would be much more expensive in the long run than would be an all-out customer relations program. (I was reminded of the policy of a few manufacturers of much more expensive items — fly a man around the world if you have to, but make him happy.)

After talking with the technician (Mr. Tuner, he is called), I went back to my tuning. I found that the best adjustment was obtained with one of the tuning screws backed all the way out. I decided that perhaps my particular automobile has characteristics which need less capacitance than the minimum provided by the tuner. Experimentally, I removed one of the tuning screws and reinstalled the tuner. This time the vswr went down to zilch at the center of the band and to about 1.2:1 on either end.

I put it on the air and found that performance in the fore and aft directions was roughly equivalent to that which I had been getting from a 3.5 foot base-loaded trunk mount antenna. Best of all, I now had no external advertising of the CB in the car. From 20 feet, the small black wire running from the top to the bottom of the windshield is almost impossible to see.

Does it work? You bet. Is the Intenna the answer to everyone's 10 meter or CB needs? Hardly. Does it have any drawbacks? A couple.

The manufacturers of more traditional antennas need have little fear that everyone will throw away his longer antennas in favor of the Intenna. The Intenna will never set any records for long-range communications. It will never take the place of co-phased dual CB antennas for many heavy-duty truckers. But for the guy who only uses his CB on the road talking to other drivers a few hundred yards ahead or behind him, the Intenna is excellent.

For the person who wants CB or 10 meter communications but doesn't want to let every thief within eyeball distance know about it, the Intenna is well worth considering.

The drawbacks are few, but should also be mentioned. Aside from relatively short range and sharp directivity, the amount of rf energy in the car is a minor problem, particularly when there is a windshield antenna for the car's AM/FM radio.

The energy level is nowhere near high enough to be a health hazard, but it does tend to cause interference on the AM/FM radio when you are listening to music and key the mike. In some cases, you get a feedback squeal; in others, only a squelching of the AM/FM unit. Glyn admits that this is common, but also mentioned that most people turn off one radio when using the other.

The last drawback is that the Intenna should be professionally installed. If your dealer has installation facilities, this is no drawback at all. The Intenna is simple to install, but the tuning is a little critical. However, with the "Mr. Tuner" backup and the well-written instructions, any competent technician should be able to handle the job. In any event, any sale of the Intenna should be topped off by a warning to either have the Intenna professionally installed or to read the instructions very carefully. For example, the instructions state that any other *antenna* installed on the car should be removed before tuning. I found the effect on tuning nil, but the performance of the Intenna is definitely better without another antenna installed. ■

The Zeppy Vertical

-- a perfect 2m antenna

Believe it or not, a CBer came up with this antenna. Electrically it looks like a ½ wave endfed Zepp antenna with a ¼ wave section of open wire line to obtain a match to 50 Ohms.

After a couple of days I realized that here was the perfect 2 meter antenna. The main 57" element can be directly bolted to a car frame, be the top of a flagpole, or be a piece of wire directly bolted to the rig. It is better than a 5/8 wave antenna because it doesn't require a ground but has about the same gain.

I built a 57" stinger on a PL-259 plug and found that waving around the mike or touching the radio didn't affect the swr or received signal strength. A 19" piece of wire performed miserably when compared with this antenna. It's also easy to build and easy on the pocketbook. ■

A Cure for Antenna Self-Destruct

- - a mod for your Ham M

Robert H. Johnson W9TKR
505 South Elmwood
Waukegan IL 60085

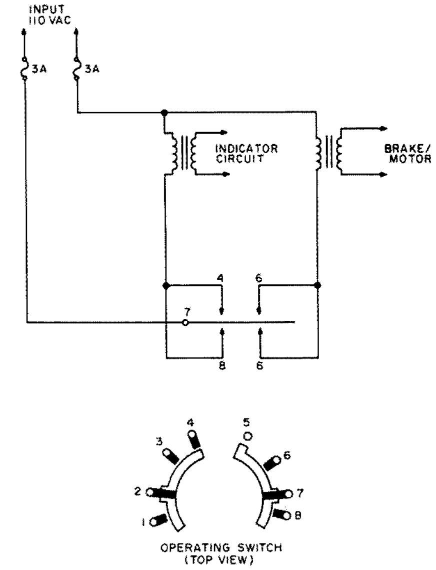

Fig. 1. Original circuit with diagram of operating lever switch as viewed from the top.

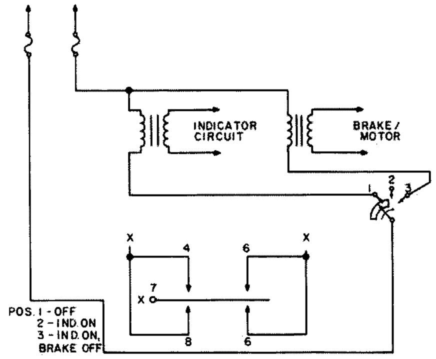

Fig. 2. Modified circuit using 3 position progressive shorting type rotary switch. Original connections are removed from lever switch at points designated by X.

During the 1971 annual meeting of W9DXCC in Chicago, there was a discussion concerning the problems involved in "instantaneous" braking of antenna arrays. This discussion was quite an eye-opener, and provided much food for thought, and no little worry, as the figures mentioned concerning the stresses involved when a rotating antenna is suddenly brought to an abrupt stop by a mechanical brake were really quite astounding. This sudden strain can be damaging to the rotator, mast, antenna, and not least, the tower itself.

This article will present a simple modification to the Ham M rotor control box which provides manual control of the brake position, and also allows indication of antenna direction, with or without rotation.

All that is needed to complete the modification is a switch and the rerouting of three wires, with no external circuitry outside of the control box required.

The three position switch provides:

1. Off: No primary power to control box.
2. Indicator meter and lights on: Provides continuous indication of antenna direction without rotation, and with brake applied.
3. Brake disengaged, meter and lights on, ready to rotate using normal lever switch.

It must be mentioned here that the transformer which supplies power to the indicator and the lamp circuits is rated for continuous duty, while the transformer which supplies the rotor motor and brake solenoid has a duty cycle of only 10%. This means that it is important that, after watching your antenna coast to a nice smooth stop, you return the switch to position 2 for continuous indication with brake applied, or to position 1, power off. A spring return switch might be useful here, but not absolutely necessary. If you like, a small neon indicator lamp with a 100k series resistor could be wired from position 3 of the added switch to the other side of the ac line to indicate that the brake is disengaged, and to remind you to return the switch to position 1 or 2.

Fig. 1 shows a portion of the original circuit, while Fig. 2 shows the modified circuit, using a rotary three position progressive shorting type switch. Fig. 2(a) is an option, if you prefer using a 2 pole three position rotary. A DPDT toggle switch, with center off position and a long mounting bushing, could also be used.

Modification is done as follows:

Unplug the ac power cord to the control box and remove the multiconductor cable from the terminal board at the rear of the unit. As you remove the conductors from the terminal screws, make a note of the colors and the corresponding terminal numbers, for ease of replacement later.

Remove the screws in the four mounting feet, and lift off the control box cover. Note that there are two blank holes provided just below and to either side of the meter. You will use the right hand hole, viewed from the front.

The switch you use will mount in this hole, and must be small enough to maintain

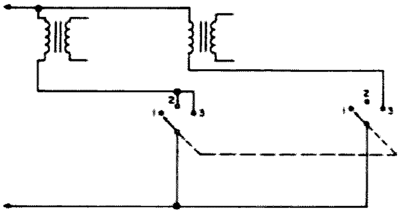

Fig. 2(a). Modified circuit using a 2 pole three position rotary switch.

good clearance between the switch terminals and surrounding metal parts and components. A hole must be drilled in the cover to clear the switch shaft. Be sure to drill this hole in line with the existing hole.

Refer to Fig. 1 for a diagram of the existing lever switch. Remove the wire from terminal 7, and connect to the center arm of the new switch. Remove the wire from terminal 8, and connect to position 2 of the new switch. Remove the wire from terminal 6, and connect to position 3 of the new switch.

That's all there is to it, unless you wish to use the indicator lamp mentioned earlier. You can now watch your antenna coast to a smooth stop, instead of coming to a jarring, metal-shearing, abrupt halt. You will soon learn to anticipate the amount of coast after you release the rotate lever, in order to reach the desired direction. The amount of coast or "gear down" will depend on factors such as the size and weight of your antenna, and the wind velocity.

Remember to switch the brake back on to "stow" the antenna when you are not rotating it. ■

Quick Antenna Insulators

-- when DX won't wait

Recently, while I was building antennas, my supply of insulators ran out. As Murphy's Law would have it, none could be found in town. The result was that I could order replacement insulators, overpay, and be delayed several weeks, or I could figure out another alternative. Since I was anxious to get on 20 meter CW as quickly as possible, I decided to build some myself. This resulted in a method for using plexiglas to fabricate insulators quickly and cheaply.

Thanks go to Larry K8ZSQ, who donated a strip of plexiglas 10' x 1" x ¼". The plexiglas was cut and drilled according to the dimensions given in Fig. 1. Sections A and B were joined using epoxy cement. After the epoxy had been allowed to cure, the dipole elements were added and soldered. The RG-58/U was added and joined to the elements beyond the point where the elements joined the center insulator in an effort to reduce strain on this connection and, hopefully, to prevent it from breaking.

Finally, the entire center insulator was weatherproofed with bathtub caulk and taped well.

To date, three such dipole antennas have been built on the HF bands and perform well. ■

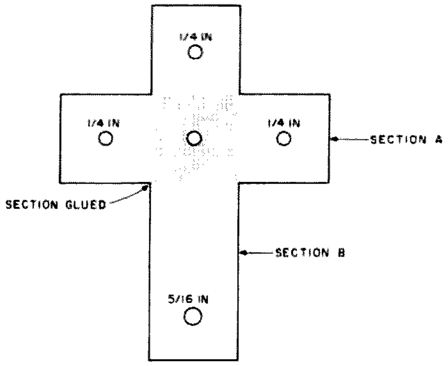

Fig. 2. Completed center insulator.

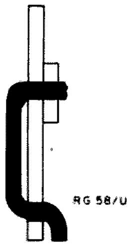

Fig. 3. Side view showing RG-58/U inserted in the insulator.

Raising A Tower?

- - don't forget zoning!

As amateurs, most of us have zoning problems only when we try to put up our antennas. While the FCC regulates our indoor activities, local land use controls affect antenna sites outdoors. We have all heard horror stories about former DX chasers reduced to the 2 meter ranks after moving to an area which prohibits towers, or expensive towers staying up only long enough for the neighbors to complain to local officials. Such disasters don't have to occur and, with a little knowledge of zoning, you can avoid similar problems.

Your best opportunity to deal with zoning regulations is when you are moving to a new home. In such cases, you have the opportunity to choose the regulations you would like to live with. The first step is to familiarize yourself with the zoning ordinance for the new area. Visit the local planning department, which is usually located in or near the city hall, and explain your situation. Tell the planner you talk to that you are moving into their jurisdiction and describe your antenna installation to him. The planner should be glad to talk to you; it is always easier for him to explain the regulations to somebody before they have their tower up in the wrong zone. Ask which zones towers are permitted in and where they are not. The planning department will have a map which shows the zoning district boundaries. Look the map over and get an idea where you can locate. You might want to mark a few zoning districts on a city map to take with you when you look for a house.

You will probably find the ordinance treats towers in the following ways, depending on the particular zone in which they are to be located: 1. permits them outright; 2. permits them with conditions; 3. permits them only with a special permit; or 4. prohibits towers.

The first situation is obviously the best. Simply go to the building department, get your building permit (the Uniform Building Code requires a permit for towers or poles), and put up your tower. Don't forget the building permit; it's your insurance policy. If your neighbors complain or the laws are changed, your tower is safe only if you have the permit.

Not many people will have the ideal situation. Most jurisdictions permit towers only when certain conditions are met. For example, I recently moved from a city where towers were allowed only when located at least 20 feet from my property lines. Where I live now, towers are permitted only after the building department has reviewed the tower plans to be sure the structure is safe. Some zones have height limitations on structures, including towers. The list of possible conditions is long, but the important point is to be sure your particular installation can meet the requirements. If so, go get your permit and consider yourself almost as lucky as those whose towers are permitted outright.

The other zones, those where special permits are required or where towers are prohibited, should be avoided. However, I suppose an unfavorable zoning restriction is like TVI; sometimes it's there, so you have to deal with it.

Overcoming an unfavorable zoning obstacle is generally done in one of three ways: with a variance, a conditional use permit, or a rezone. Each remedy is useful for certain types of problems. Usually, variance provisions are only established to provide flexibility from dimensional regulations in special situations. In other words, setback or height restrictions can sometimes be eased through the variance process. Don't ask for a variance to build a tower in a zone where it isn't permitted, because a variance is the wrong tool for that situation (it's like trying to measure current with a voltmeter). If you think you might be a candidate for a variance, ask the planning department if there are special conditions which have to be demonstrated before the variance can be issued. Realistically evaluate the standards and if you still feel you qualify, apply for the variance.

Conditional use permit provisions are sometimes in zoning ordinances for an interesting reason. When the city council first considered adopting the zoning ordinance, there was a group of citizens vehemently opposed to allowing a certain use (such as towers) as a matter of right in a particular zone. Another group was equally outspoken in its desire to have the towers allowed. The council, in its wisdom (it was

probably an election year), didn't want to make either group angry, so they voted to allow towers in that district only after a public hearing for each proposed tower.

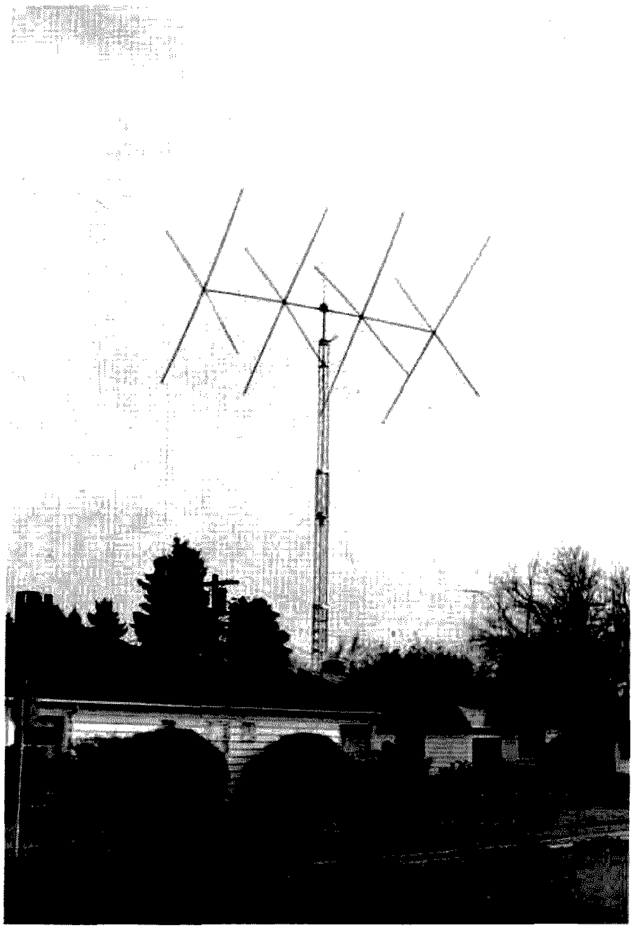
Try to assess your chances for a conditional use permit before you apply. Ask the planners if others have obtained permits in similar situations. Also, look around in the neighborhood for antennas. It may help you obtain a permit if there are other antennas in the same area. Last, talk to the neighbors, explain what you want to do, and see how they react. If you are lucky, the neighbors may sign letters indicating support for your project. If your chances for a permit look good, apply.

Remember, your odds for success are helped by favorable testimony at the hearing and by your ability to design your particular tower installation so that it is compatible with the neighborhood. You should be prepared for the hearing with pictures of your tower and antenna at similar installations. If necessary, offer to keep the tower cranked down behind the garage or to limit the size of the antenna array. If you can anticipate the arguments of those opposed to your tower, you can defuse much negative testimony before it occurs. For example, most neighbors are concerned about possible TVI. Be sure to tell the hearing board early that the FCC regulates and monitors your activities to prevent interference with other services.

Rezones are generally a last resort, to be applied for only if towers are prohibited outright or after you have tried and failed to obtain a variance or conditional use permit. Simply, the object of a rezone is to have your property placed in a different zone, one which permits towers. However, a zone which permits towers may also permit undesirable uses that would prevent the rezone. Generally, unless you are immediately adjacent to an existing zone which you would like to extend to your property, chances for a rezone are small. Ask the local planners or your attorney for advice before you apply for a rezone.

There is one other tool which is often overlooked. If your attempt for a rezone fails, it is sometimes possible to amend the ordinance provisions for the zone in which you are located. Possibly, a prohibition in the ordinance could be changed to a requirement that all towers be less than 50 feet high. Talk to the local planners about the procedures to follow in initiation of a proposed zoning ordinance amendment. Often, it is easier to change the ordinance then it is to obtain a rezone.

There are a few final points to remember. First, zoning regulations are not the only restrictions on land use; often subdivisions have restrictive covenants placed on the lots. These restrictions can be found on file with the county auditor and you should read them carefully, because restrictive covenants can be very powerful and hard to change. Second, if you have found a house you want to buy and don't have time to check the restrictions, you can make an offer subject to the ability to obtain a building permit for your tower and to locate a tower within the subdivision. Last, good luck, and remember that most zoning ordinances are easier to read than you think, especially when compared to the FCC's regulations. ■



The author's recently erected tower and antenna. An inquiring neighbor was told by the local building department, "He has a building permit; it's perfectly legal."

Remote Rain Gauge

- - for gauging remote rain

Richard A. Little K9EEH
407 15th Ave.
Sterling IL 61081

For those of you who have a rain gauge, and would like to know how much rain fell without going out and checking, build this simple indicator for use inside the house.

Drill very small holes at whatever markings you want on your gauge. Use stiff copper wire and epoxy. Use about a 100 Ohm resistor for current limiting to the LEDs.

Make up any type of indicator panel for use inside the house with the LEDs. Label next to each LED the same reading as on the rain gauge so when that light comes on that will be how much rain you have in the rain gauge. ■

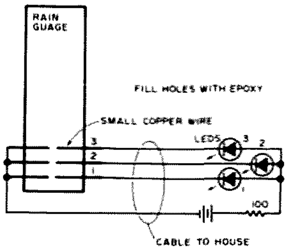


Fig. 1. When the water gets up to the first marking, water will short across wire and turn on LED #1 inside the house.

Super Loop Antenna

- - great for apartment dwellers

To the urban amateur or apartment dweller, operation on the 80 and 40 meter bands often is out of the question. The main problem is where to put the antenna. Various schemes, some of them ingenious, have been tried with varying degrees of success. Each has had its drawbacks. In preparing a book on amateur antennas, I felt that there was a need for a simple indoor antenna that the average Novice could build economically, that would produce the results needed to encourage the neophyte further into the hobby. The worst problem exists on 80 meters, and it was there that this experiment centered.

After trying numerous configurations, it was decided that a closed loop offered the best hope. Loop antennas are often treated as a specialized class. Little has been written on them, in comparison to the volumes written on other configurations, so little is known of them by the average amateur. Except that they can be a bit tricky to tune, there is no rational reason – it's just a class of antennas that has never been fully explored.

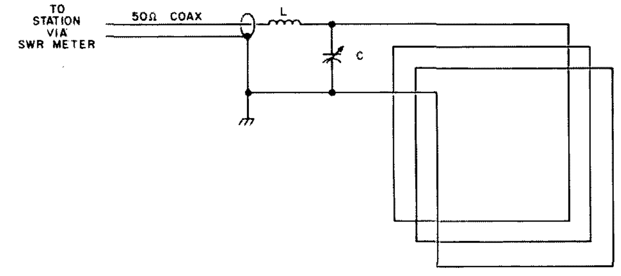

Fig. 1. 130' wound in 3 turns 2" apart. L – 7 uH, 24 turns, 3/4" diameter, 1-1/8" long. C – 365 uF.

One thing that is known, however, is that a loop can be a very efficient radiator *if* it is properly matched to the transmitter. There is where the big hole is; few loops are matched to their associated equipment, and the consequent poor results quickly discourage the user.

In spite of its apparently large size, the loop described here is in the class known as small loops. A small loop is one in which the total length of the wire used is small compared to a wavelength. Current in a small loop is all in one direction, and is fairly uniform in magnitude. This loop uses a full 130 feet of wire – just ½ wavelength. It is consequently about as big as you can get and still have a small loop.

Small loops behave as large inductors. They can be tuned to any frequency at which they're still small loops with the appropriate capacitor. Their radiation is polarized perpendicular to the plane of the loop, and nearly omnidirectional in the plane of the loop, with virtually no radiation in the directions perpendicular to the plane of the loop. This may seem a contradiction to the next statement because of the polarization. A small loop is considered in engineering circles to be a magnetic dipole. That is, it does with the magnetic component of the wave what a dipole does to the electric component. Being primarily magnetic in its behavior, it is relatively insensitive, when receiving, to lightning and man-made static.

The Super Loop, then, is the largest possible small loop, positioned horizontally, and matched to the transmitter with a simple L network. It is made with common doorbell wire, since it is used indoors. Doorbell wire comes in standard lengths of 65 feet, so two rolls make a nice half-wave antenna. It was wound around the wall of the room near the ceiling, the turns spaced about two inches apart. Where the ends came together, the L network was mounted, and 50 Ohm coax fed down to the equipment.

The L network consisted of a 365 uF "broadcast" variety variable capacitor, one of the few parts still easily obtained, and a 7 microhenry inductor. The inductor was made by winding 24 turns of #18 wire on a scrap of ½ inch PVC pipe, also easy to obtain (½ inch pipe has an *outside* diameter of ¾ inch). When close wound with #18 wire, the length of the winding is 1-1/8 inches. If other wire size is used, it should be space wound to fill the specified

length.

The initial tune-up of Super Loop can be a stinker, and a reflected power meter is recommended. Set the antenna tuning capacitor to about 2/3 of its full capacity. With your transmitter set for reduced drive, tune it up as you would a conventional installation. Then set the reduced power meter for swr and tune the antenna capacity for a dip in swr. Finally, repeak the plate tuning capacitor of the transmitter. Because of the relatively small impedance transformation, the output tuning capacitor (sometimes called the load capacitor) of the transmitter can interact considerably with the antenna tuning capacitor. It is here that things can get sticky. The trick is to find that point where the two seem to produce minimum swr. Once that point is found, the loop can be relatively easy to use.

The first experiments with the loop brought almost fantastic results until it was discovered that the loop was proximity-coupling into my outside wire. When the outside wire was taken down, results seemed more rational. Good signal reports were obtained with satisfactory QSOs as far as 1000 miles or more. The worst results came from just over the horizon, which is to be expected, since the loop is a low radiation angle device because of its horizontal position.

Swr averaged around 1.4 throughout the band, thanks to the L network. I have good reason to suspect that the dimensions of the loop have some tolerance, since it has the variable capacitor across it. There being no "ends" in the wire, the so-called end effect does not apply, and the loop dimensions are governed by the wavelength in space. As long as there is a fairly small side-to-end ratio, the form factor isn't too important. Simply adjust it so that the half wavelength of wire makes three full turns.

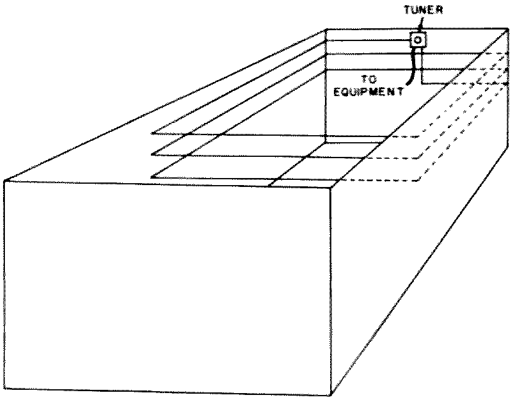

Fig. 2. The loop is wound three times around the room near the ceiling. It's nice if it just fills the room, but it doesn't have to. Also there's no reason why it cannot be mounted on the roof.

I have good reason to suspect that the behavior of the loop will vary somewhat from one location to another, since there is no way of predicting what length of conductor will be within its field to affect it. Nonetheless, based on the reports I've had, I think I might be on to something. The only truly valid test is its use in many different locations, and while I have several amateurs working on loops, it will be quite a while before the results can be fully evaluated. Based on the results to date, I feel it safe to at least offer the amateur world what I've done so far and hope that those who use this antenna will feed back their results. ■

Wright-Patterson AFB OH 45433

Rock Bottom 2m Antenna

- - uses converted CB components

Surprisingly good results can be had in low power 2 meter mobile work by using a 5/8 wave whip as the radiator rather than the standard ¼ wave whip, as is generally well-known. In practice, I've found that actual on-the-air results are much more favorable to the 5/8 wave whip than the roughly 3.4 dB theoretical gain improvement would suggest, to say the least!

Home brewing a 5/8 wave mobile antenna is a simple proposition, but presents a few mechanical problems as well as occasional difficulty in getting a good match to 52 Ohm coax, so most fellows tend to purchase the antenna as a complete package from one of the major mobile antenna manufacturers. Costing $25-40 or more, these units do an outstanding job of upgrading that mobile signal, but a very professional-looking, good-performing 2 meter antenna can easily be fabricated for a few dollars, particularly if use is made of some low cost CB-type antenna fittings and components.

The antenna described in this article consists of a standard CB-type, "no-holes" trunk lip mount, a modified CB loading coil, and a 47" stainless steel whip. In my case, the entire installation was completed for $11, using a budget-priced CB antenna ($10 at Olson Radio) and a 47" whip obtained for $1 at a local hamfest.

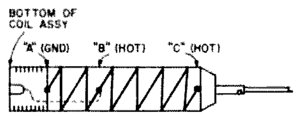

Fig. 1. Point A-B: impedance-matching shunt coil (at dc ground); point B-C: loading coil. Although "hot" for rf, note that the coil is at dc ground, since the shunt, connected to B, is at ground dc potential. Note: "Hot" center pin of coil assembly is factory connected to point B internally.

To modify and install the antenna, first carefully follow the CB antenna manufacturer's instructions for installation of the trunk lip mount. The optimum antenna location (other than roof-mounting) is usually on the forward trunk lid, at the center of the vehicle. The RG-58/U coax can be brought forward through the rear deck to the operating position. Be sure to inspect the coax carefully — some CB antenna manufacturers furnish a very inferior product. If the braid appears thin and the inner conductor can be seen through it, discard the coax and replace it with a 16-18 foot length of high quality RG-58/U. Also, ensure that the set screws in the mount make a good dc contact with the trunk lip, and that the coax isn't pinched as it emerges from the mount. Check the mount and coax for continuity and shorting.

Next, discard the short CB whip furnished with the antenna package. (In the case of the Pace CB antenna I used, the very short 34" whip included was cut down to 19" to make a ¼ wave handie-talkie antenna for improved performance over the usual "rubber ducky," or it can be base loaded to form a ½ wave HT whip as described by K3VNR in July's *73 Magazine.*)

In any case, replace the short CB-type whip with a 47" stainless steel whip of the type usually available for a dollar or so at hamfests, flea markets, and various surplus outlets. Be sure to obtain a whip that will slip into the stud provided with the CB antenna; a collapsible rigid whip is not recommended.

The next step is to disassemble the loading coil. When the plastic cover is slid off, you will find two coil windings, a small shunt-wound impedance-matching portion at the base, and a dozen or so turns of #14-16 wire which constitutes the loading coil proper, as shown in Fig. 1. Both windings must be removed. Once this is done, wind five (5) turns of #14 or #16 PE wire around the coil form between points "B" and "C" as shown in Fig. 2. An impedance-matching shunt coil isn't required for the 2 meter antenna.

The antenna is tuned using a good VHF-type swr bridge at the transceiver, adjusting the coil spacing slightly and/or the antenna length using the set screw adjustment in the stud at the top of the loading coil. In my case, 5 minutes worth of simple "tweaking" adjustments produced a very nearly "flat" 1:1 vswr over 146-148 MHz. Once adjustment is completed, the plastic coil cover can be slid into place, swr rechecked, and the coil cover cemented and sealed for weather protection.

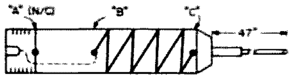
At W8FX/m, the inexpensive Pace CB antenna kit used did not use a spring;

actually, a spring is unnecessary and may in fact cause some radiation efficiency loss at 2 meters if used. However, the installation could be varied to include the spring and, if the CB whip used were a relatively long one (some are 39-41"), the added spring length could obviate the need for acquiring a new whip. If a spring and slightly shorter whip are used, then some experimentation with the number of loading coil turns would be required (try 7 turns for starters).

This article points out a specific mobile antenna design, but it also serves to highlight the "gold mine" of antenna fittings and parts which have been mass-produced for the CBer but which can, with some ingenuity, be readily "appropriated" for ham use. Similar construction possibilities exist with respect to 10, 6, 1¼, and ¾ meter antennas. For example, a turn or two off the original CB coil will resonate the antenna nicely within the 10 meter band; a few turns on a cannibalized loading coil will turn the same 47" whip into a dandy ¼ wave 6 meter mobile antenna, merely requiring interchange of the loading coil itself. And, a mag-mount, mirror mount, or gutter clip-on might be just right for your van or VW installation instead of the trunk lid mount. But consider that the overall effectiveness of the antenna depends to a great extent on getting a good ground to the auto body and getting a good, fairly symmetrical ground plane under the antenna. For these reasons I'm leery of using these other types of mounts.

A real boost for this kind of project comes from the fact that mobile CB antenna kits are now available in discount stores for as little as $10-15, making cannibalization painless, and both Olson and Radio Shack (among other distributors) are now selling individual replacement CB antenna parts (coils, mounts, whips, studs, springs, etc.). Another source of CB antenna components is the local CB dealer who may have lying around "junked" antenna coils, springs, mounts, etc., available at a bargain price, and which may be "rehabilitated" for your purposes. Of course, if you already have a CB mount installed, and who doesn't these days, all that is required for this 2 meter antenna is an extra coil and 47" whip.

Fig. 2. Note: Shunt winding between points A and B is removed, as is original loading coil between points B and C. A new coil of 5 turns of #14-16 PE wire is substituted from B to C. Coil and antenna rod are now "hot" and no longer at dc ground.



As with any antenna project, the "proof is in the working," and work it does. I use this antenna with a Wilson HT at 2.5 Watts output, consistently working several Dayton area and out-of-town repeaters out to distances of 40-50 miles. Side-by-side comparisons using a ¼ wave whip on the same vehicle invariably favor the 5/8 wave antenna, both on receive and transmit. Gratifying results have also been obtained in simplex work.

In addition, the installation has, as a bonus, the feature that fittings are compatible with regular CB antennas; at W8FX, the same mount doubles as a base for the ol' CB antenna, with a 2 position coax switch on the dash switching the antenna lead from the 2 meter rig to the CB set. Future plans call for making similar interchangeable antennas for 6 and 1¼ meters, using the same mount and coax lead-in.

Who says CB hasn't produced some good side benefits for hams? ■

Antenna Gain Facts

-- don't be misled

This will be a short article to discuss the gain of antennas. I always get confused when someone quotes me a gain of a particular antenna. The confusion arises because I don't know what baseline or reference point he is using. Normally, in measuring HF antenna gain, the figures are referenced to those obtained by using a horizontal dipole (halfwave). In the FM communications field, the reference for gain is still a halfwave dipole, but mounted in the vertical plane. As far as the FCC rules are concerned, antenna gain is based on a halfwave dipole as a reference. This can be important because many antenna manufacturers use an isotropic source as a reference for listing the gain of their antennas. A common antenna (and the simplest) is the 1/4 wavelength whip perpendicular to ground plane. By comparison to an isotropic source, this antenna shows a gain of .3 dB. Additionally, the 1/2 wavelength antenna shows a gain of 2.1 dB over isotropic or 1.8 dB gain over a 1/4 wavelength antenna. The common 5/8 wavelength antenna, that we see so often on the mobiles, has a gain of 1.2 dB over the 1/2 wavelength or 3.3 dB over isotropic. Higher omnidirectional gain is usually accomplished by using stacked halfwave dipoles. As an example, four stacked halfwave dipoles on 146 MHz can provide approximately 6 dB gain. Usually the maximum number of halfwave elements stacked vertically will be eight (8), which should provide an omnidirectional gain of about 9 dB. ■

Antenna Type	Gain
Isotropic	.0
1/4 wave	.3
1/2 wave	2.1
5/8 wave	3.3
Collinear	6.0

The 8JK Array Revisited

-- inexpensive and effective

Tim Soxman W3ZVT/4
P.O. Box 375
Shaw AFB SC 29152

Being an antenna nut and cheap also makes one look for inexpensive and effective antennas capable of getting the most out of the rig. A good example of such an antenna is the "8JK". Various articles in the past have treated this type of antenna as a rotary beam on the higher bands (20, 15, and 10), but very little material has been available for the lower frequencies. Since the estimated gain of such an antenna is 3-4 dB, it becomes an attractive alternate to running higher power. I shall attempt to examine various configurations of such an antenna and provide some insight into possible uses. The *ARRL Antenna Handbook* devotes some space to the 8JK (p. 207). The spacing outlined in the handbook is .1 wavelength, which in the case of the handbook antenna is used to reduce the antenna feedpoint resistance. It should also be noted that the radiating elements are cut as a driven element/reflector combination. This may be fine when such an array can be rotated, but the idea of building such an antenna for the lower bands soon leads to problems. The thing that isn't too readily realized is that the directivity of such an antenna, if both radiating elements are of equal length, is governed primarily by the antenna feed phasing. When this premise is understood, one can then see that a 3-4 dB 80 or 40 meter bidirectional beam can be readily constructed. See Fig. 1.

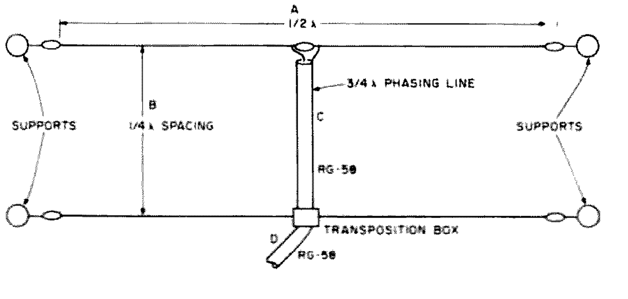

*Fig. 1. A = 468/fMHz; B = 234/fMHz; C = (702/fMHz)(V); D = (468/fMHz)(V). V = line velocity factor. Values for a 3.9 MHz: A = 120'; B = 60'; *C = 118.8'; *D = 79.2'. *Based on a .66 velocity factor.*

The thought of sinking four poles and cluttering up the landscape probably won't enchant too many people, so let's look at a less painful way of achieving the same result. How about just two poles (trees, etc.)? Okay, how about a bidirectional inverted V beam? Would you believe just two 30 foot poles? The normal inverted V with a 90° apex angle has predominantly a vertical angle of radiation, so let's use a 120° apex angle to enhance the horizontal radiation characteristic. On 80 meters, this means the support for the antenna apex will be approximately 30 feet tall. This would be easily handled by TV masting, since the antenna elements can be used as guys. See Fig. 2.

The inverted V arrangement also provides a plus in that trimming of the antenna to resonance is facilitated due to the accessibility of the element ends.

The key to this antenna is the transposition box. This little jewel provides the necessary phasing line transposition to change the directivity

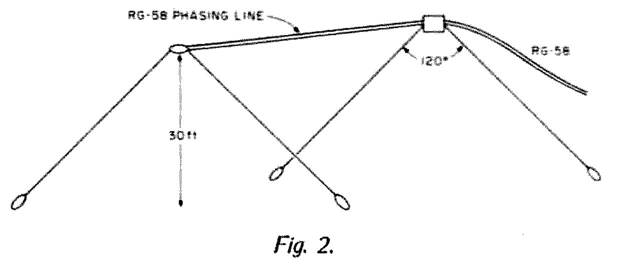

Fig. 2.

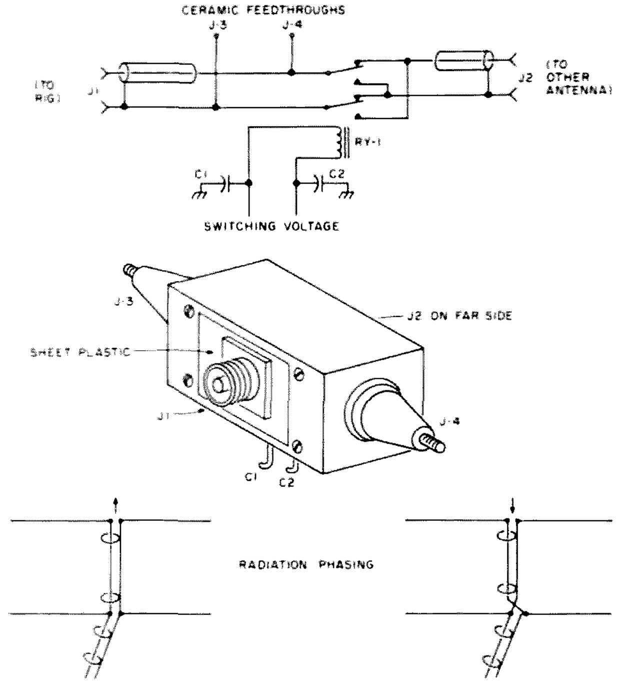

Fig. 3. RY-1 – latching relay; C1, C2 – .001 uF feedthrough. Note: J1 and J2 must be mounted on insulated bracket or plastic wall in minibox.

of the beam. Fig. 3 details the construction and wiring of the box.

The dimensions outlined are for 75 meters, but may be adjusted for other bands. The antenna feedline should be in multiples of an electrical half wave (don't forget the velocity factor). The 3/4 wave phasing line length must be computed using the same techniques.

The same approach may be used vertically with line transposition providing the directional capability. Of course, if you really want to get wild, the addition of a coaxial relay and an additional antenna along with its attendant 3/4 wave phasing line will enable you to punch up 3-4 dB gain in the north/south or east/west directions. See Fig. 4. ■

Tower Installation Techniques

-- using rope guys!

Many self-supported towers and beam antennas are blown over and lost each year unnecessarily, causing insurance rates to escalate for all tower owners. Those who lose towers are frequently at fault because of excessive top loading, excessive mast height, or lack of indicated guying. Inexpensive rope guys can save costly replacement of towers and beams in almost all cases, and it is very satisfying to be worry-free during windstorms.

Many years ago a guy wire untwisted at an egg insulator on a rooftop tower, and a new Telrex beam was lost when it dove into an oak tree. A 60' Easy-Way tower, crank-up, tilt-over type, was installed next at ground level with a ground post support. The tower seemed rather flimsy to hold a beam without guying, so at the suggestion of another amateur, WB4QPH, who already had a similar tower, ¼" polypropylene rope, from Sears mail order, was installed in six directions at the top of the tower.

These original rope guys are still in service after about eight years, but two more rope guys were added in the NW, W, and SW wind directions and one additional guy added in the NE, E, and SE. The additional guys were added after the tower was nearly lost when a guy rope was inadvertently cut at the rotator mounting plate during a windstorm. Also, the tower was increased to 70 feet when an Easy-Way top section and a 10/15 Duobander beam were added, a tribander beam was changed to a 204BA monobander, and a 2 meter 8 element beam was added on top of the mast.

The top section, including the 10 foot extension, was bent roughly 15°, just above the second section, when the rope guy was cut at the rotator plate. The top section could not be lowered, and there was no room to tilt the tower over because of trees. However, it was possible to lower the second section inside the lowest section, so the bent tower point was only about 20 feet above ground. All of the guy ropes were brought around to the proper position, and the tower was carefully brought back to plumb after several sitings vertically along the tower. The top section could then be lowered and still is in use. This shows that with guy ropes, a tower can be straightened sometimes, without dismantling. But extra guy ropes should be immediately installed.

A few years later, a 100' Heights tilt-over aluminum tower was obtained from an amateur who moved away. While this tower was of heavy duty construction, with the topmost section spaced wider than the lowest section of the Easy-Way tower, six x ½" polypropylene rope guys were installed for added safety. One of the reasons was the questionable reliability of the 5' high tilting arrangement with its small boat winch and quadruple pulley. The boat winch was immediately replaced by a two speed Gold winch. One of the guy ropes was over the top of a 70' oak tree, and this was used to ease the tower down initially and hold it if anything happened to the tilting arrangement. Then, when the tower was tilted about 45°, it was eased down with a rope sling between two trees, for added safety in the position of greatest torque on the tilting device.

After about a year and a half, the ½" rope guys on the 100 foot tower completely disintegrated, probably from the sun's rays. However, a full refund was obtained from Sears when the ropes were returned. These polypropylene ropes had blue and yellow strands, while the original ropes, still in use, have black and white strands. It was then urgent to obtain new guy rope because I was in the midst of the 80 meter part of 5BDXCC on two-way SSB. A heavy 80 meter beam was on the 100' tower, consisting of tunable 80 meter cliffdweller driven elements, spaced 32'.

Fortunately, through a nautically inclined amateur, WA9NUQ, I obtained a catalog from West Products, 161 Prescott St., East Boston MA 02128. This firm offered a utility grade ¼" nylon rope at a very reasonable price, and I ordered 2000 feet, with an explanation of the intended use. The order was quickly filled as requested, but with ¼" Dacron rope, at only slightly increased cost, and the suggestion that this was much better for the application. In view of the increased rating and less stretching of this rope, I installed only 6 guy ropes on the 100' tower, along with pulleys for various antennas

on the 70' and 100' towers.

Since then, two other amateurs have benefitted from the extra rope I ordered. We are all very satisfied with Dacron rope for tower guying because it is stronger, has less stretch, the knots don't slip as with polypropylene, and, finally, it is softer and much easier on the hands. It can be coiled up without gloves, when a tower is dropped.

There are several advantages with rope guys, other than keeping towers up in windstorms, which may not be realized. Perhaps the most important, and possibly most controversial, is complete freedom from guy wire reradiation effects and any loss of front-to-back signal ratio, as well as front-to-side ratio. Regardless of the use of insulators in guy wires, various resonances occur, and these can be verified with a grid dip meter along each guy wire. It is difficult to prevent reradiation effects from guy wires over all amateur bands.

Rope guys also eliminate even closer coupling effects between wire guys and 40 or 80 meter "slopper dipoles," inverted V antennas, quads and delta loops. Another advantage with rope guys is the protection against lightning discharges following down a guy wire and jumping to a house. Recently, in a neighboring town, an amateur's house and contents, including a large station, were badly damaged by a fire caused by a guy wire conducted lightning discharge. And, of course, guy wires are hazardous near power lines, and especially with crank-up towers.

Finally, the cost of rope guys is minimal considering all of their advantages and the added safety factor in preventing loss of towers and antennas from wind damage. But liability and property damage insurance is still needed for coverage of unexpected, catastrophic losses. ■

An Ultimate Invisible Antenna

-- works well when it's not raining

The arrival of the first transmitter at the home QTH raised two problems. How would the neighbors react? How does one get an antenna away from trees? The trees were too close together for a dipole on 80 meters and too tall for an inverted vee anywhere near the transmitter. As a joke, one student suggested using the downspout and gutter.

From 1972 through 1976 this was the only antenna I used. It put out enough signal to work both coasts on 40 meters and work several foreign countries on other bands with a very limited home operating schedule.

The antenna is quite simple. The gutter is nailed to the eaves of the house in the normal manner. A drainspout runs down the side of the house from the eave trough to a tile in the ground. The drainspout was cut off just above the tile and a hole drilled in it for a self-tapping metal screw. A single feed wire was run from the rig in the basement to the downspout and was attached with the self-tapping screw. As a Novice, I was limited to 75 Watts. Fortunately, feeding the wire directly from an SB-102 resulted in no ill effects to the finals. The move up to Advanced allowed me more power, so I used a home brew ultimate transmatch to lower the swr.

At the present cost of parts for a transmatch, the beginning ham might use a tuned feeder. Tuning is done by taking a long piece of wire (maybe 10 feet more than necessary) and cutting short sections off the wire until the antenna loads on the desired band with a low swr. If more than one band is desired, another lead-in wire can be used. One lead wire may be necessary for each band desired, but sometimes one is lucky, and one lead-in might serve 2 or more bands. The lead-in wire used here is solid copper insulated wire.

Allband operation can be achieved by using tuned feeders for each desired band and connecting them to the output of a rotary switch. The transmitter is connected to the switch (which should be in a well grounded metal box) by a piece of coaxial cable. The operator selects the band simply by moving the switch.

I took the time and effort to tune a feeder for 40 meters and have an swr of 1:1 at 7.15 MHz and an swr of 3:1 at the band edge.

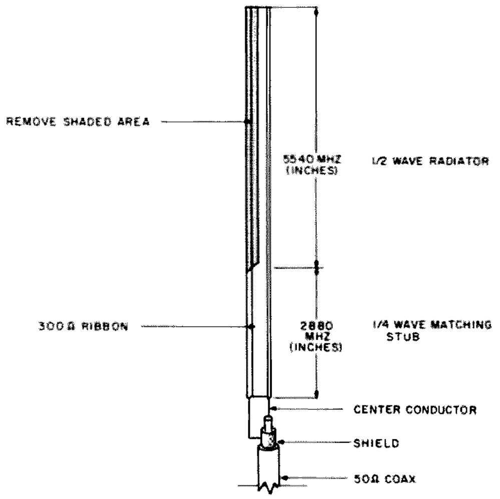
I have a continuous aluminum gutter and have not tried this on a gutter made in sections. The sections may cause some TVI, but there has been no problem here except on channels 2 and 5. My well-tuned dipoles cause the same amount of problem. The transmitter should be well grounded when using this antenna. Otherwise, rf builds up on the case and can lead to serious shocks. ■

Mountaintop Special Antenna

-- fits in a backpack

C. O. Klawitter W9VZR
4627 North Bartlett Avenue
Milwaukee WI 53211

If you like to camp, mountaintop, operate portable on vacation, participate in Field Day activities, or possibly need a quick temporary antenna at a new location, the antenna described in this article will be just what you are looking for. Although this antenna was designed for ten meters, it can easily be adapted for six and two meter use by adjusting the length according to the table which accompanies the diagram.



J-pole antenna.

The antenna is the good old standby – the J-pole. It was selected because it has a half wave radiator, nice low angle of radiation, could be constructed of inexpensive 300 Ohm ribbon, has its own simple, built-in quarter wave matching stub, can be directly fed with 50 Ohm coax, has a low vswr over a large bandwidth, and can be rolled up into a light small package. How can you go wrong with all those advantages? It's almost like perpetual motion.

The diagram shows its general construction. Use either a knife or heavy shears to split or cut the 300 Ohm ribbon down to the matching stub, and then carefully remove the unwanted portion. The coax is simply soldered to the end of the 300 Ohm ribbon, weatherproofed with a plastic spray, and then wrapped with black plastic tape for additional weatherproofing and strength. RG-58/U cable was used to keep down the weight and should be satisfactory for lengths of thirty feet or less. The top end of the matching stub and the half wave radiator were also sprayed and taped. To mount the antenna, I tape twenty-five feet of nylon rope onto the end of the antenna. A nylon cord could be passed through the dielectric at the top of the antenna for its suspension.

When trees are available, tie a rock around the rope and use a strong arm to get the antenna mounted. This may take a little practice. From personal experience, I would make these suggestions: Watch out for windows, wear a football helmet, make the points on the antenna where you have added tape as smooth as possible, and try to stay a quarter wavelength away from large pieces of metal. I think those suggestions are self-explanatory. Even after I had taken all of these precautions, the rock came loose from the rope, fell on the 300 Ohm ribbon, and cut the antenna in half.

Well, I still think it is a good idea, and it has proved successful. I have also included a table determining the antenna length for those of us who flunked fifth grade math. ■

Frequency (MHz)	28.0	28.5	29.0	50.0	51.0	52.0	144	145	146	147

Fiery Endfed

-- keep antennas ice-free!

The winter of 1977, so I've been told, was the worst in over 100 years, at least for the Midwest and the East Coast. Coming from California where the weather is always warm, I was led to think that the simple endfed random length wire was the ideal solution to the problems of operating in a dorm room or apartment. But moving out to the snowy, icy chill of New England left my ideals in a frozen heap of wired snow, collapsed ignobly on the ground. The results were a badly mismatched transmitter and disastrous signal reports.

Every place in which I've had the fortune to dwell always has had at least one window looking out toward a tree, pole, or other building. With a little bit of nighttime or early morning rock-throwing, arrow shooting, or flycasting, I've been able to secure a nylon line to that remote support. Then, a wire is slinked out, made fast, and a primitive but effective matching network employed to fool my poor FT-101B into thinking that a 37 foot piece of copper is a 50 Ohm dummy load.

This works great until you find out that snow, a funny white stuff which apparently falls freely all winter everywhere except California, is made out of water. Water weighs over 8 pounds per gallon — it doesn't take much snow to accumulate on a skinny piece of wire and make it *very* heavy. After a particularly nasty storm blew its way into Boston in our wonderful winter of '77, guess what happened? My lovely wire antenna snapped under its unwanted icy-white burden, leaving the transceiver in grave doubts as to whether its pi-network would ever be duped again by coils, capacitors and random copper.

There are three solutions to this problem. One is to move back to California as any sane person would do. However, in my case at least, the phenomenon known as graduate school prevents me from being counted among the sane. The second is to do what the power company, Ma Bell and the rapid transit people do — use enormously thick and strong cables with reinforced supports so that even if the frozen Charles River were encased around the wire, it wouldn't give a bit. But thick copper wire can get very expensive and cumbersome and also violates the ideal of having as invisible an antenna as possible, so that the RFI complaints get directed elsewhere.

The third way is to take advantage of the slightly higher resistance of thin copper wires over the big fat ones. I ran a twisted pair of #24 insulated wires out to my support with the ends soldered together at the far end. When I use the twisted pair as an antenna, I merely connect the two ends together at my end and feed the whole mess as a single wire. But come the ires of Mother Nature and buildup of ice on the line, I disconnect and separate the two wires at my end and feed some current (dc or 60 cycle, not rf) into the resultant loop to make it toasty warm. The ice melts, and the strain is off the antenna. This heated antenna idea really does work. All you need is a variac and a hefty filament transformer (whatever is handy), and you can power the thing up. Once the ice is off, relatively little current (wires not even warm to the touch) is needed to keep the antenna clean of white stuff.

Use a copper wire table to determine the resistance of the wire and be sure to double the figure for the measured length of the antenna, since it's a loop out and back. Don't get carried away with the heating juice, or you'll burn up your snowbound antenna and really be the victim of fiery irony!

Some excessively clever soul will no doubt come up with a tension-actuated switch which would automatically disconnect the antenna, separate the two ends of the loop, and feed in the heating current once the pull of the line increases with snow buildup.

The light weight of the #24 twisted pair and its ability to shrug off snow at the turn of the knob result in an antenna which is durable and resistant to wind and storms. It even serves to radiate rf power quite effectively from its associated transmitter, heating up the ether and, on occasion, the coldest winter in a long time. ■

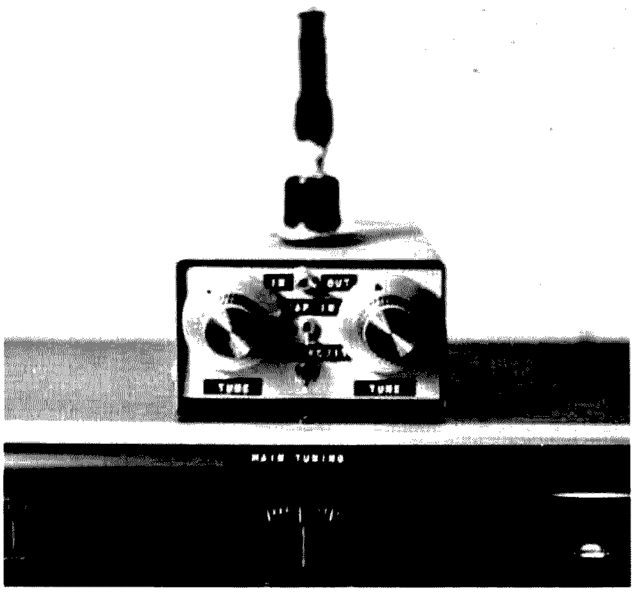
Build A Vacation Special

-- portable antenna systems

Frequent moves and periods of extended travel associated with Air Force duty bring to focus the need for a compact combination receiving antenna and rf preamplifier system.



The circuit shown in Fig. 1 combines the requirements of compactness, portability, and low cost in a unit that can be built for roughly $10-$15, using mostly junk box parts. The unit, housed in an attractive aluminum and gray mini-cabinet, makes a handsome and very professional-appearing adjunct to any general coverage receiver.

Transistors Q1 and Q2 may be substituted for. If an RCA 40468 FET is substituted for Q1, a fourth lead (a shield wire) will be found coming from the body of the transistor. This should be connected to ground. Other component values are not critical. The three mini-toggles are relatively expensive, but often can be found at local surplus outlets or at swapfests for as little as 35¢. The 47" stainless steel whip was obtained at a local hamfest for a dollar.

Though solid state, the unit is probably most easily constructed using conventional wiring techniques, using the switches and a couple of multiple terminal strips as convenient mounting points. Most of the components are mounted in the area formed by the "U" shape of the lower portions of the mini-box. The rf input coil and tap selector switch are conveniently mounted on top of the cabinet, as is the type F, BNC or SO-239 chassis mount antenna connector – use whichever type you prefer.

The whip selected can be inserted into the cable connector selected and epoxied into it – at W8FX, type F connectors are used, so that the 47" whip doubles as a 5/8 wave 2 meter antenna for high performance work with a Wilson handie-talkie.

A single pole, 20 position rotary switch is used to select the optimum tap on the input coil. While a switch having fewer or more positions could be substituted, the 20 available tap positions allow good continuous coverage with the 47" whip from 160 to 10 meters, including the SWL and utility bands in between. The coil is wound on a 1/2" wooden dowel with about 150 turns of #28 PE magnet wire, tapped at 3, 7, 12, 18, 25, and then about every 10-11 turns. After connection to the rotary selector switch, the coil can be epoxied into place.

A short length of RG-58C/U coax terminated in a PL-259 connects the unit to the receiver. The only internal adjustment required is setting the optimum value of R1, the 2k Ohm potentiometer. This is done by turning the unit on, peaking the antenna switch for maximum received signal strength, and then peaking R1 for maximum gain. Check all bands to see if any oscillation is encountered – if so, back off R1 slightly until it

disappears. The setting of R1 can then be left alone.

L1, C1, and C2 form a pi network input circuit, while S1 allows the capacitors to be switched out of the circuit if desired. (C1 and C2 are not strictly necessary and may be omitted if desired, with little performance degradation. S1 would then be omitted.)

Transistor Q1 is a MOSFET type with very high gain, which is protected against excessive gate voltage caused by nearby transmitters; Q2 serves as an emitter follower to match the medium output of the MOSFET (Q1) to the low input impedance of most receivers.

One caution in construction is to exercise care in the handling of Q1. Its gate is quite sensitive to static charges, and therefore it should be handled with a short circuit across its leads until just before power is applied to the circuit. Also, don't apply a soldering iron to Q1's leads unless they are shorted to one another.

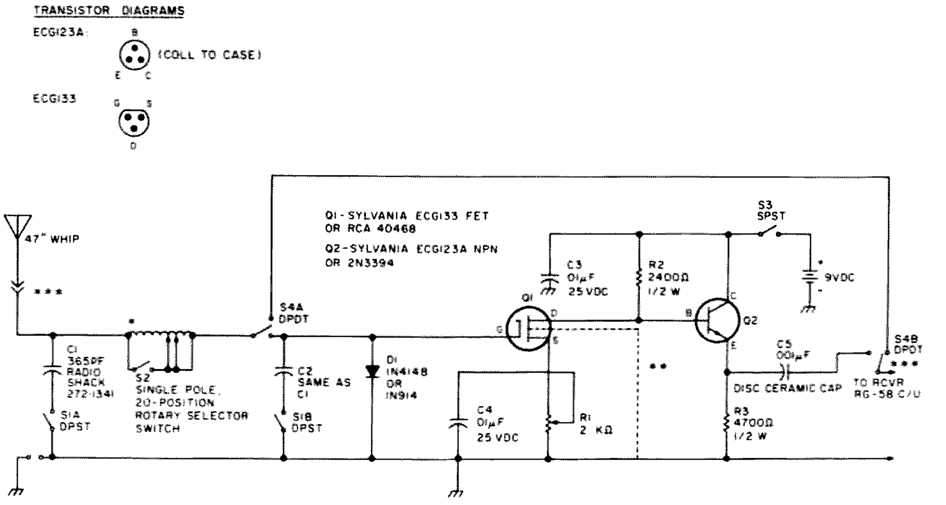


*Fig. 1. *150 turns #28 PE (see text). **Shield wire if RCA 40468 is used. ***See text for type connectors.*

A standard 9 volt transistor radio battery powers the preamp. A source of 9-12 V dc could be obtained from the receiver, but current drain is so small that this is unnecessary.

The overall result is a super sensitive, versatile receiving system featuring an overall gain of more than 30 dB. It has been used with good results on several communications receivers, such as the Yaesu FRG-7 and Allied/Radio Shack SX-190. In fact, results seem to equal those obtained from the 20-50 foot random wire usually strung out for casual portable listening. Of course, the unit can double as an allband preamp used in conjunction with the regular station antenna, although cross modulation and overloading effects may be troublesome unless an rf attenuator is used ahead of the FET input. ■

Brooklyn NY 11224

Apartment Antenna Specials

-- next, hide your Mod 19

All you apartment dwellers – get ready. Here are a bunch of ideas for how to hide antennas, run cables and set up a shack. (The nosy body on the fifth floor will never know you're there.)

The biggest problem for apartment dwellers is usually how to put up an antenna. Actually, we apartment owners have it made – in my case I have an antenna height of 190 feet. Not bad, eh?

To start off, if you have access to the roof, that's great! But, of course, we all know that most apartment owners are not even allowed to put any protruding objects outside of their windows. "Protruding objects" means antennas. One of the best ideas for an apartment owner is a long wire or dipole. With that there's only one problem – how to put it up. Stringing the antenna between two buildings would be ideal. If that's not possible, the next best thing, and probably most common, is a wire antenna strung along the apartment windows. To start with, there is absolutely no way you can have an apartment shack without a transmatch.

When you are putting an antenna up try to keep the antenna from touching the building. If this happens chances are it will short out. Also, always get as much wire out as possible. Use the thinnest, most durable and least likely to be seen wire that you can find. If possible, paint the wire the same color as the building. Try to get the antenna at least four or more feet away from any obstructions. Any antenna you can get outside is better than an antenna inside. Don't let the antenna dangle; always pull it tight.

One of the best ways I know of to support the antenna is to put 1" x 1" x 4' strips of wood on the window. Put screw eyes in these strips to attach the antenna to, but don't tie the antenna directly to the screw eye. There should be an insulator between the antenna and the screw eye. Galvanized wire going from the tip of the strip to the top of the window helps to support the antenna. Don't hesitate to pay for a good support. A well constructed antenna won't come down until you take it down.

Now, I have a word to say about coax. Try to keep coax runs shorter than 15 to 20 feet. If you must make a run longer than this use RG-8/U. Usually when you string an antenna around an apartment you use RG-58/U since it is much more flexible than 8/U. If you have to go around corners with coax, use 58/U and try as much as possible not to put sharp bends in it.

If you are putting up a dipole, have the coax come straight out of the bottom of the antenna. Try to insulate the center of the dipole. (A Plexiglas™ block is ideal for this purpose.)

Let's get off the subject of antennas before we get dizzy from the height. A lot of people ask how to get a good ground in an apartment. To tell the truth there is no really good ground. The best thing to use if you can't knock a ground rod a couple of feet into the ground is a water pipe. If your shack isn't in the bathroom then you probably don't have a handy water pipe. The next best thing is a radiator pipe. For a good connection to the pipe, scrape away all the paint. The best thing to use to connect the wire to the pipe is a hose clamp.

When you set up your shack always try to put up shelves above the desk. Try also to get all your equipment within reach without having to get up. Standard connectors throughout the shack are absolutely necessary. Don't bolt your paddles or key directly to the desk. And, as for a desk, just about anything will do except a collapsible table. They usually can't hold the weight.

Your shack should be close to a window and water pipe of some kind. Try not to have your entire shack plugged into one outlet or . . . "Standby OM, the circuit breaker just went!" Don't put any wires under carpets. Don't even think about not getting lightning protection devices. When possible try to keep your power output as low as possible.

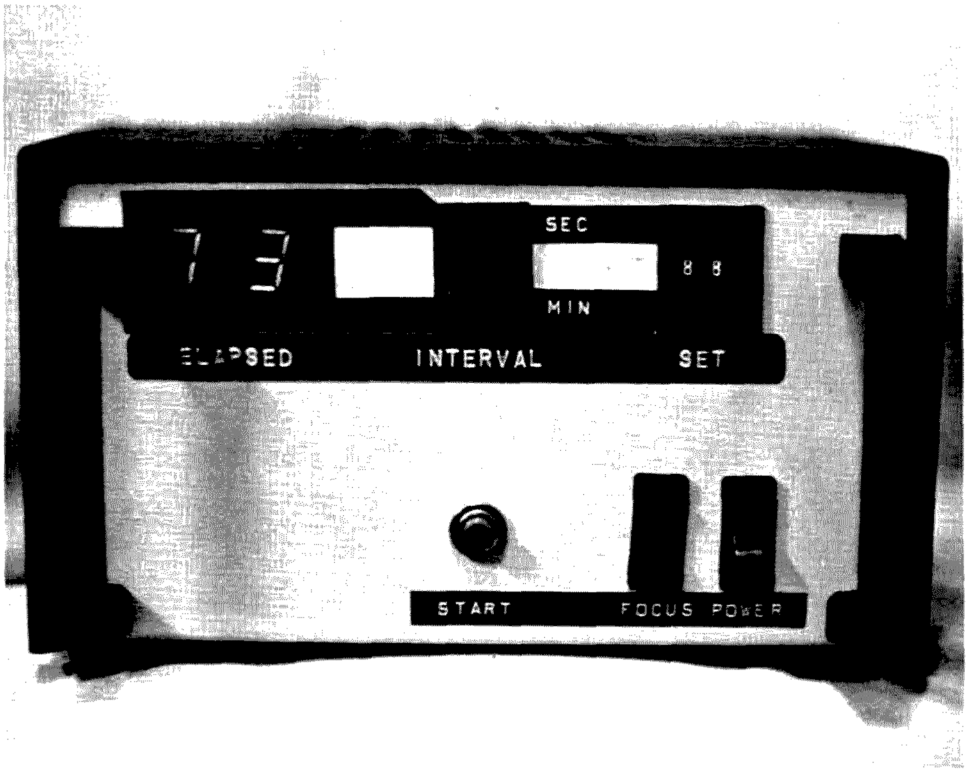
At all times do everything in your power to prevent TVI. The fewer people who know you're a ham, the fewer people there are to blame you for TVI. Stay away from 6 meters.

To sum it all up, it isn't so bad living in an apartment. Just try to use every bit of space you have. I hope you are able to use some of these ideas to help you put up a better antenna and enjoy amateur radio. And, if you have any ideas or inventions for apartment dwellers, please send them to me. ■

Build A Unique Timer

-- for the ham photographer

Front view of unit.



Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

The need for electronic timers must be ubiquitous. One certainly gets this impression from the number of timer articles published in the various electronic magazines. There are repeater timers, identification timers, phone call timers, Polaroid timers, and egg timers. One even suspects there are timers that are intended for uses which could not be discussed in a family magazine. Many have been suggested for photographic work; however, each of these has certain defects which prevent it from being an ideal enlarging timer. The ideal timer for darkroom use must accomplish several tasks:

1. Timing in seconds to at least one minute for routine exposures;
2. Timing in minutes to at least 15 minutes for mural or special work;
3. A rapid, foolproof way of entering time interval desired;
4. Indication that the time cycle is progressing, and elapsed time;
5. Automatically extinguish safelight when enlarger is on;
6. Allow for "focus" or non-timed on state;
7. Allow interval to be interrupted for "burn-

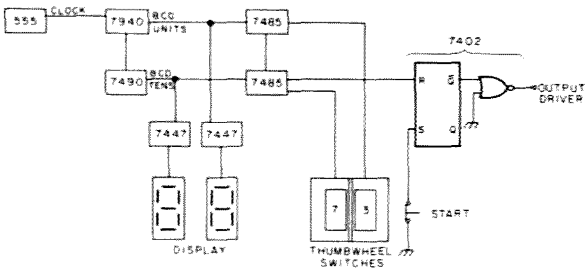


Fig. 1. Block diagram.

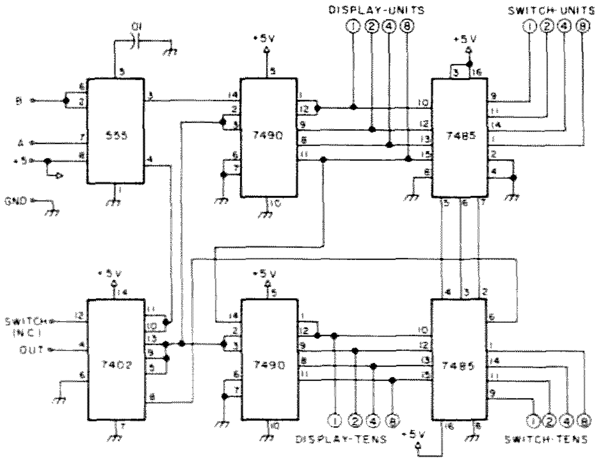

Fig. 2. Main board schematic.

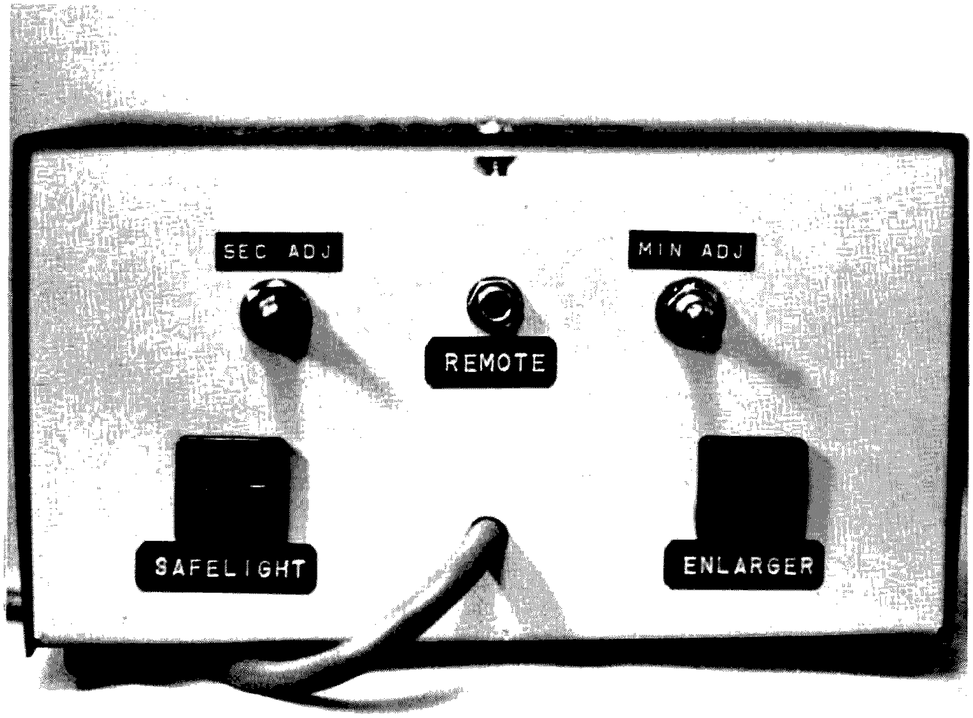
ing-in."

By an amazing coincidence, the timer described in this article does just these things!

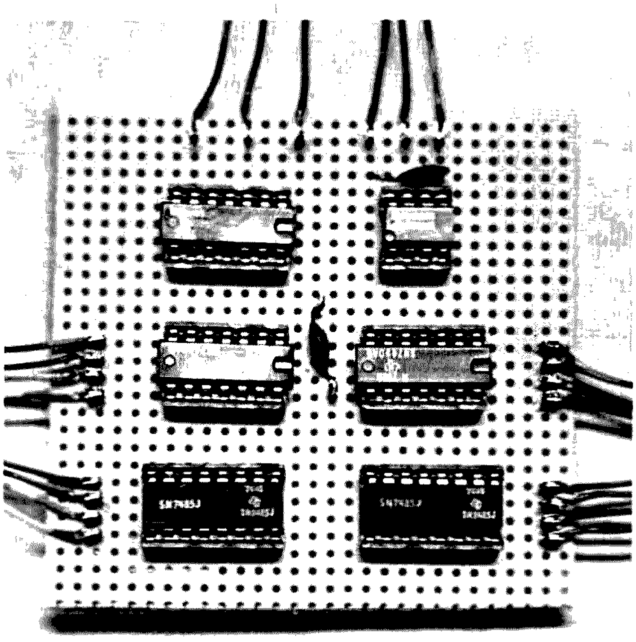
A glance at the completed unit will illustrate the major features of the timer. Time desired is entered through two binary coded decimal (BCD) thumbwheel switches on the upper right corner of the front panel. A two digit, seven segment light emitting diode (LED) readout, located in the upper left corner, begins at "0" and counts up to the time preset, then automatically resets to zero. A large rocker switch in the upper center of the panel selects an interval of seconds or minutes. A "center off" position stops the count, to allow for a "hold" in the timing interval. Timing itself is started by depressing a momentary contact push-button in the center of the panel. A second rocker switch, located next to the power switch, activates the timer output, to energize the enlarger socket and extinguish the safelight *without* disturbing the timing interval, for as long as needed for focusing and composition. On the rear panel, grounded ac



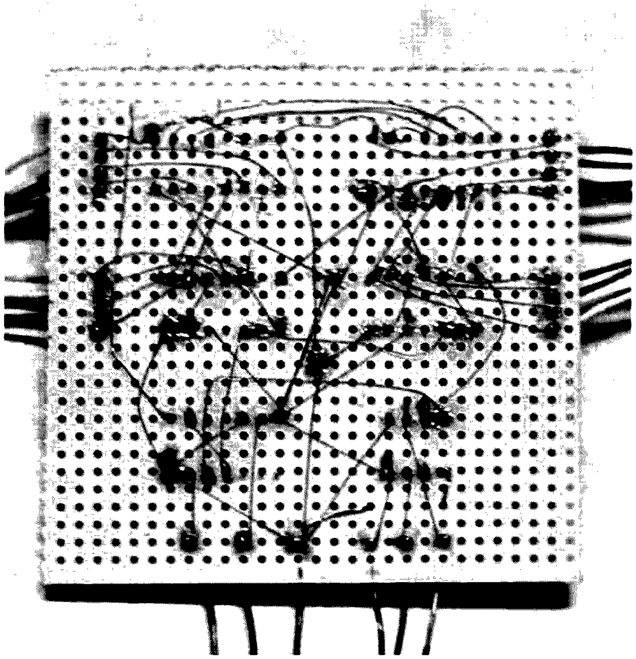
Rear view of unit.

sockets are provided for ENLARGER (*on* during timing interval) and SAFELIGHT (*off* during timing interval). Additionally, a phone jack is provided for footswitch or remote triggering of the timer operation. Potentiometers adjusting second and minute intervals are also located at the rear panel.

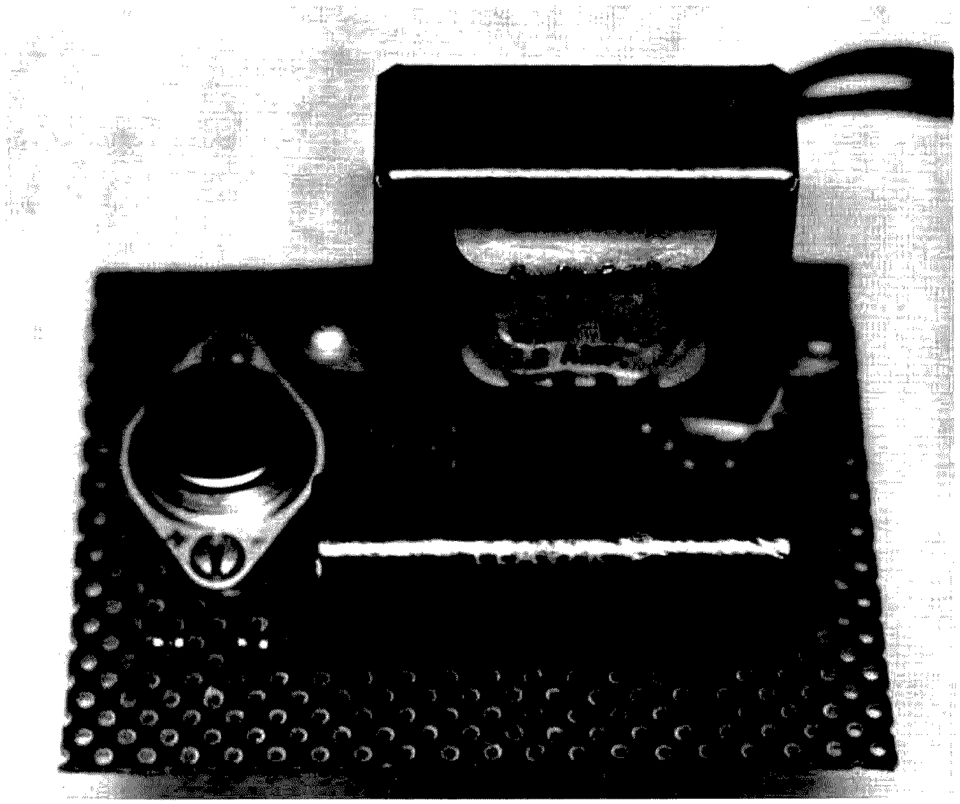
The timer is designed in a modular format, with separate circuit boards for each subunit. The power supply, main timer board, display, output, and complement generating sections are individual perfboards in the prototype. This allows flexibility in construction, and ease of modification or updating in the future. Printed circuit layouts for the



Main timer board, component side.



Main timer board, underside, showing wiring done with Vector wiring pencil.



Power supply board.

major boards are included for readers who wish to duplicate this method of construction.

A look into the circuitry of this unit is interesting, and provides a practical lesson in TTL logic devices. The versatile 555 timer chip sets the pulse for this circuit. Either 1 Hz (one pulse per second) or 1/60 Hz (one pulse per minute) is derived from suitable components in the astable mode. This clock output then goes to a pair of 7490 decade counters, connected in cascade. The BCD output of the 7490s is available at the board edge for coupling to the display board. Internally, the output of each 7490 is routed to the A input of a 7485. This chip, which has seen little use in amateur publications, is a four-bit binary comparator. Taking two four-bit binary "words," and BCD is just such a "word," it will give a "1" output if the four bits at the A input are identical to the four bits at the B input. Alternately, "greater than" or "less than" outputs may be selected so that the output is high with A greater than or less than B, respectively. Cascade inputs and outputs are available, and are used here, so that output from a

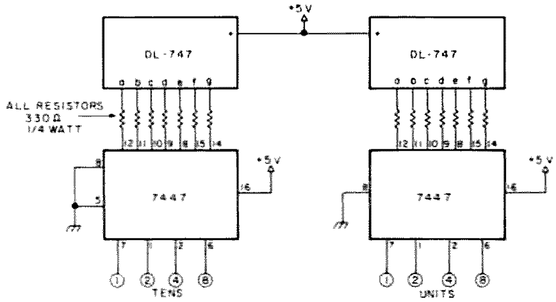


Fig. 3. Display board schematic.

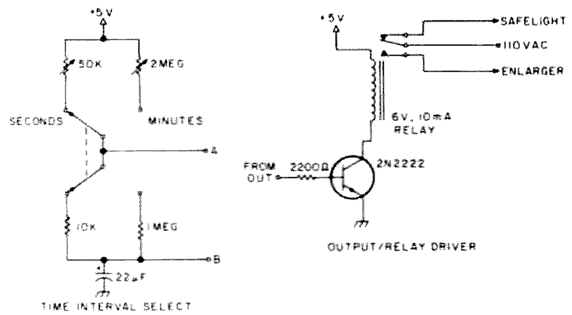

Fig. 4. Peripherals.

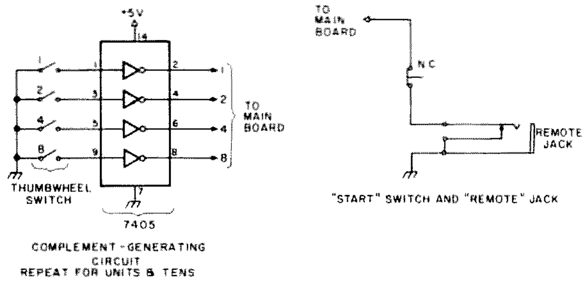

Fig. 5. Options.

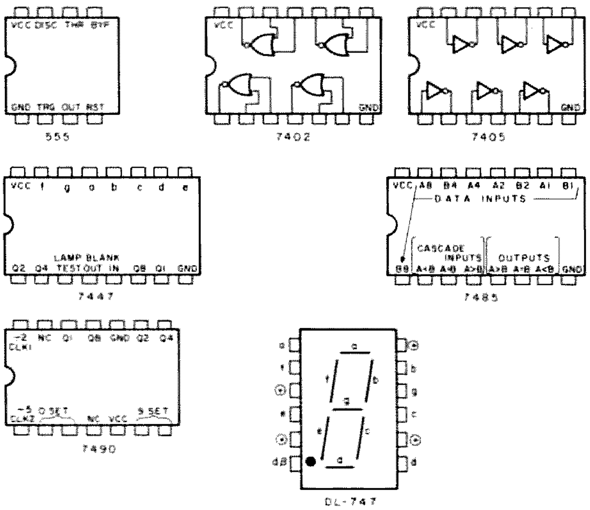

Fig. 6. IC and device basing diagrams (top view).

given chip is dependent on the next chip up the line. Here, the "1" from the "tens" (most significant) A=B output is only available when *both* the "tens" and "units" (least significant) A and B inputs are equal. The B input to each 7485 is provided by user-defined selector switches located on the front panel, and is connected through contacts along the edge of the main board. Interface with the outside world is provided by a 7402, which has two of its NOR gates connected as an RS type flip-flop. Lifting the ground on the S input raises the 555 reset line to logic 1 (high) and starts the clock. The logic 1 output of the 7485, when the BCD count from the 7490 agrees with the preset count, triggers the R input of the flip-flop, grounding the reset line to the 555, stopping the count, and clearing the 7490s to zero. An output state is then available, which is inverted with another NOR gate in the same chip, and presented for triggering outside equipment. The condition at the connector is "0" when not counting and "1" while counting.

Display is provided by a conventional seven segment LED display, with 7447 decoder-drivers. Observant readers might note the ICs on the prototype are marked SN38841. These are pin for pin equivalents of the specified 7447s. The "tens" digit is hard wired to zero blank to improve display legibility and lower current drain. Although large 0.6 inch type 747 displays were used in the prototype, any common anode display could be used. In fact, any readout capable of presenting the BCD data could be built, from four LEDs to nixies. The display could even be omitted entirely if not desired.

The B input to the 7485 requires BCD complement. Although complement mode thumbwheel switches are obtainable, only straight BCD switches were available to this writer. A small board with two 7405 hex inverters was put together to generate the complement of the number selected. If complement switches are used, omit this board entirely, and connect the switch directly to the main circuit board.

The driver/relay circuit is straightforward tradition. A 2200 Ohm resistor couples the output from the 7402 to the base of a 2N2222. The emitter is grounded, and a 10 mA, 6 V dc relay is connected from +Vcc to the collector. The power supply is also an unadorned five volt regulated supply, and no special comments are warranted. The experimenter is invited to use my circuit, or any favorite of his own.

Construction may be by any technique desired. While perfboard wired with a wiring pencil was used on the prototype, printed circuits are certainly more convenient, and layouts are included for those desiring same. Standard TTL precautions of lead dress and bypassing should be followed. Particular care should be taken in wiring the ac sockets on the rear skirt. Cabinet, placement of controls,

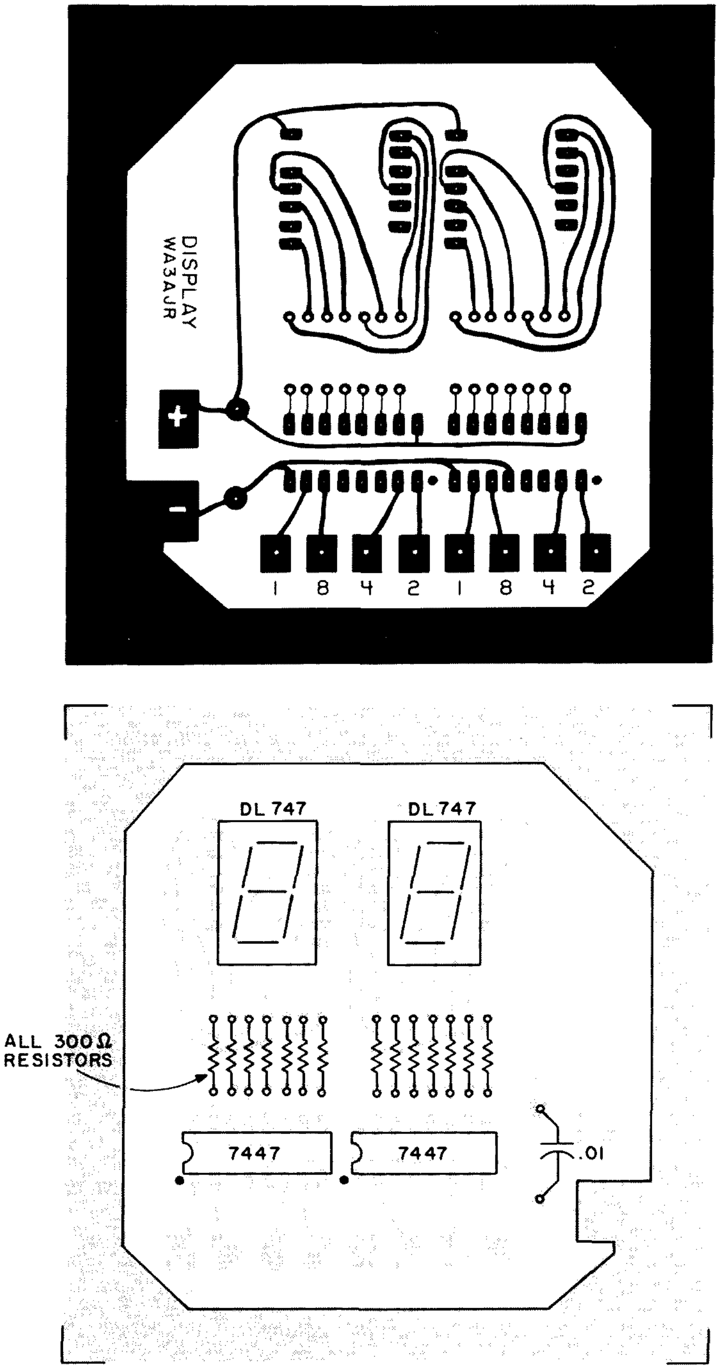

Fig. 7. PC layout, timer board.

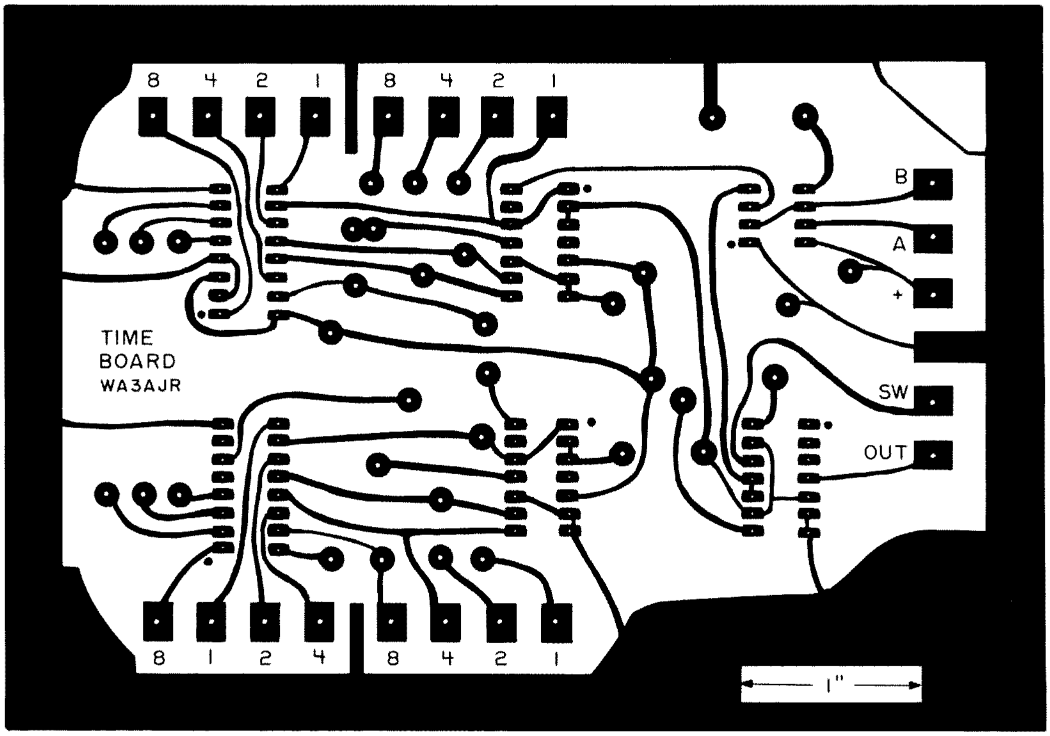

painting, etc., are left to the whims of the individual.

Once completed, the only task remaining is calibration of the timer. With the unit turned on, and the interval set to "SECONDS," plug an electric clock with a sweep second hand into the "ENLARGER" socket. Set the time to ninety seconds, and push the "START" button. Adjust the "SECONDS ADJUST" potentiometer to accurately time the 1½ minute interval. Similarly, with the timer interval set to "MINUTES," adjust the appropriate potentiometer to the correct number of minutes indicated. This does, by necessity, take a bit longer! It is important to note that, because of peculiarities inherent in the 555 timing circuit, the *first* interval will be somewhat longer than all succeeding ones. In the prototype, the difference is about 33%. Thus, the first second is really 1.33 seconds, with each

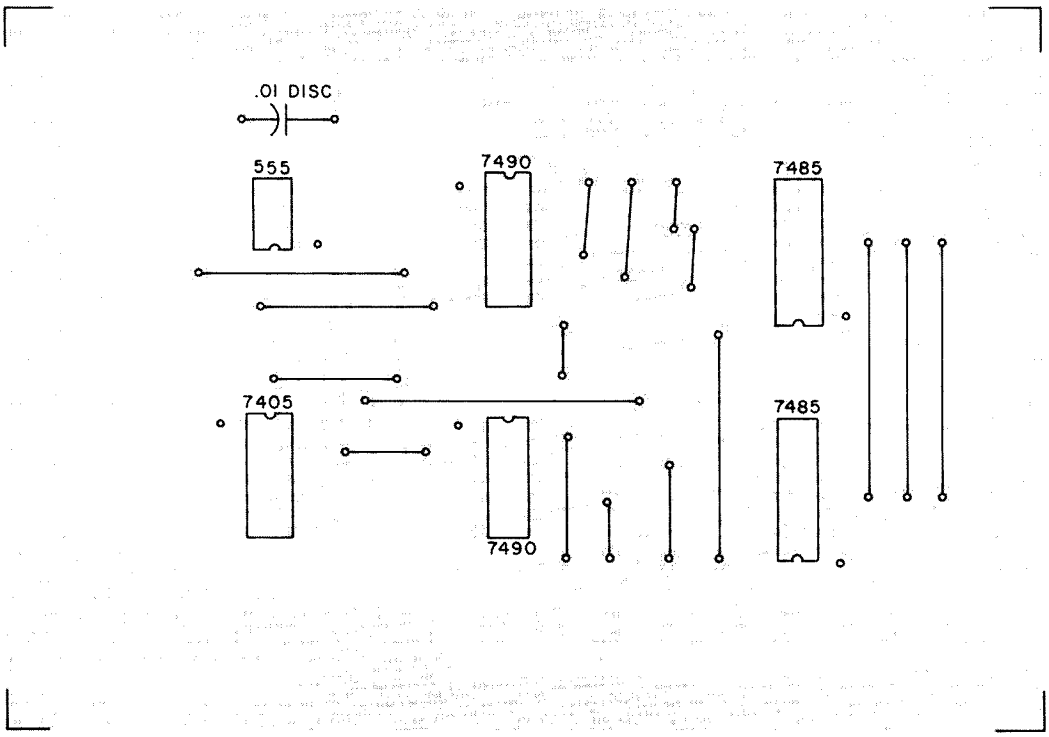

Fig. 8. PC layout, display board.

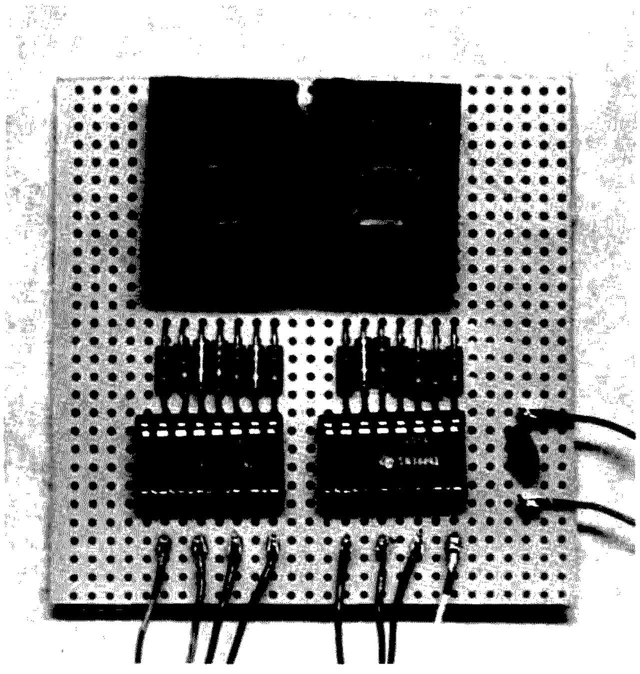
succeeding second 1.0 second. In the minutes mode, the first interval is 80 seconds (1.3 minutes) with each succeeding minute 60 seconds. For all but the most critical applications, this error, once acknowledged, is acceptable. Further, remember that the stated accuracy of a 555 is 3%, or within about two seconds per minute.

All right, already, "I've built the timer," you say, "now how do I use it?" Well, that all depends on what you plan to do with it! Let me assume, for the moment, that darkroom use, for enlarger control, is desired. Plug it in and turn it on; look at the display, where a single "0" should be evident. Connect the enlarger to the ENLARGER socket and the safelight to the (you guessed it) SAFELIGHT socket. Note that with the relay specified, not more than 100 Watts should be drawn from either socket. After going through the appropriate photographic manipulations to determine correct exposure time, set the desired interval on the thumbwheel switches. Interval selection would normally be SECONDS. The FOCUS mode may be used for composition and focusing as desired. When all is ready, making sure the FOCUS mode is off, hit the pushbutton and sit back to watch the numbers flash by. As the enlarger is on, the safelight should be off. At the completion of the timing interval, this situation should reverse itself.

But what else can you do with it? Set the timer to ninety minutes and plug your television (under 100 Watts, please) into the ENLARGER socket and fall asleep to Johnny Carson. Or plug a bell into the SAFELIGHT socket and let your wife use it for an expensive (although not very) cooking timer. Who knows what you might do with it? This thing is so useful, you can let your mind run wild!



Display circuit board.

So go have a ball with this darkroom and every room accessory. If you have any questions, or just want to let me know that you built one, or like the article, feel free to write. But *please*, if you want a reply, enclose an SASE. (And maybe a picture?) ■

Cooling Your Relays

-- for peace of mind

Some of my wire antennas have relay direction switching. Consequently, the relay holding times may be up to a couple of hours or so! Plus, the thought of those relays baking in the afternoon sun tends to give me nervous jitters.

I borrowed this circuit from my model railroading hobby. The basics are used to operate track switching machines. With a change in values of R and C, I found that my antenna relays operated normally, but were drawing less current, while being held open — therefore, cooler running.

Most dc relays will remain fully operated at one-half to three-fourths of the rated coil voltage. The problem is to still get the relay to snap-close under full rated coil voltage, and then shortly after, have this voltage automatically reduce to about three-fourths, to give a reduction in holding current.

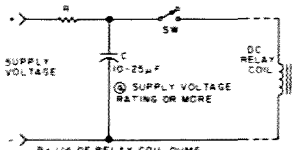

Fig. 1.

When your dc relay supply is on, and relay control switch SW is open, capacitor C will charge to full supply voltage. When SW is closed to operate the relay, the charge in C will *operate* the relay normally. However, when C's full charge is reduced by the relay coil, further full charging is prevented by the current being drawn by the coil through R. Now, the relay - coil is receiving a reduced voltage and current to hold it operated in its fully closed position.

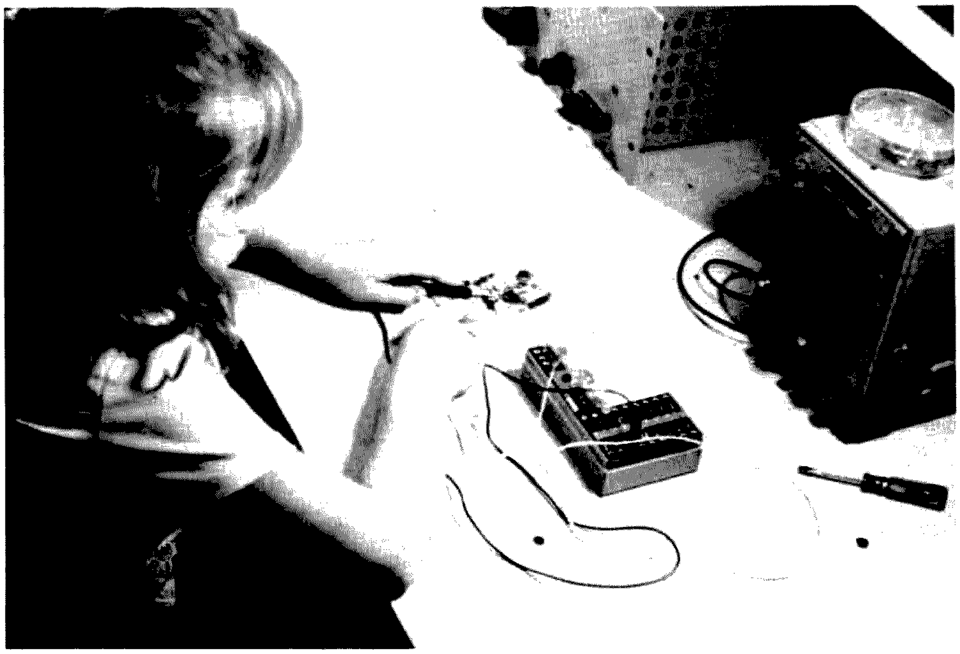
A couple of extra components are certainly worth a little peace of mind. ■

A Look At Soviet Test Gear

-- what you're missing

Sam Kelly W6JTT
12811 Owen Street
Garden Grove CA 92641

One of the more enjoyable benefits of being an electronic engineer is the opportunity to meet engineers from other countries, many of whom are hams. While working on an international program, I met engineers and trade specialists from the Soviet Union. They are anxious to improve trade relations with our country to help with their balance of payment problem. So far, the bulk of trade has been in raw materials and commodities, very dull stuff to the electronics enthusiast. Not knowing much about their equipment, I was very curious about its design, the type of semiconductors used, how good it is, and the prices. They have a state monopoly on all manufacturing industries, so all electronic equipment is sold through state trading organizations. Test equipment (VOMs, counters, scopes, etc.) is sold by Mashpriborintorg, electronic components by Elektronorgteknica, and communications equipment by Sudioimport. This approach results in a high degree of standardization throughout their country. It also results in fewer innovative designs by their engineers.



The simple panel layout and absence of switching make the U-4323 ideal for the younger experimenter.

From my contacts, I received two pieces of test equipment for evaluation. Both of them had useful features not found in instruments currently on our market. The first was a small multimeter, the U-4323. It is designed for the hobbyist and ham radio operator. It is similar in appearance and outward construction to many Japanese import instruments in its price class. Range selection is done by plugging the test prods into the appropriate tip jacks. Unpacking the instrument, I discovered a small package with spare diodes and a spare meter fuse. A comprehensive operating handbook — in English — complete with circuit diagrams and maintenance data was included.

A quick glance at the panel revealed that in addition to being a conventional VOM, it contained an audio oscillator and signal generator! The output of the audio oscillator is a 1000 Hz square wave. The rf output was fixed

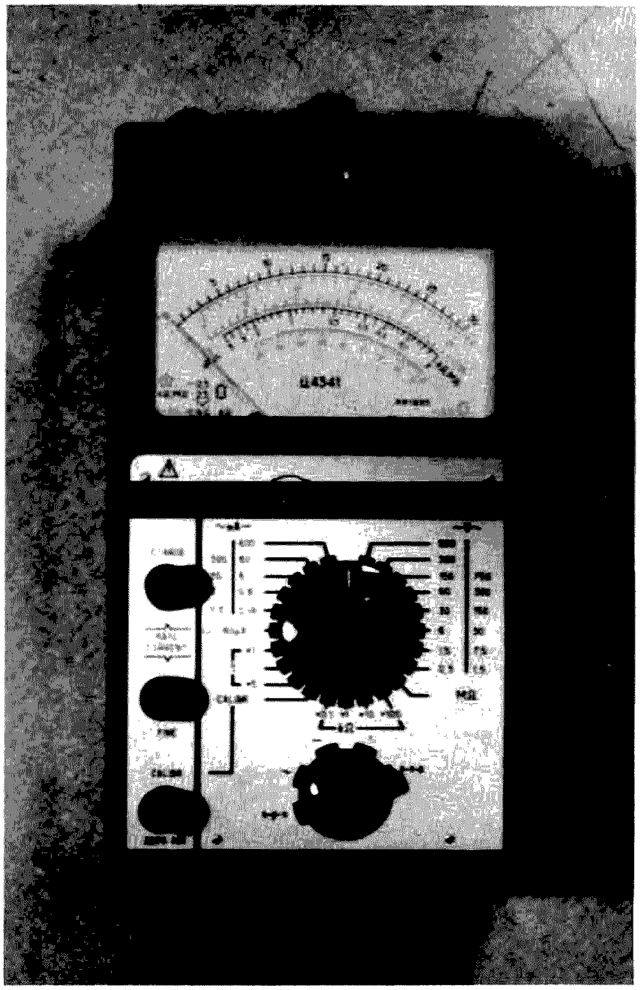
at 465 kHz, the standard i-f for their country. It was modulated by the 1000 Hz square wave. A quick check with my communications receiver revealed that the harmonic content was quite rich. It was usable as an alignment source to well above 30 MHz. The output level of each of the outputs was a good solid 0.5 volts. The circuit is quite clever, using three germanium PNP transistors. Two are used for the 1 kHz multivibrator, the third is an L-C controlled oscillator which is base modulated by the multivibrator. The packaging of the transistors was quite distinctive, being a combination of the T0-5 style and the old "top hat." All components appeared to be very well made, particularly the meter movement, which is a rugged taut band type of construction. Diode protection is also provided.

The little handbook is quite comprehensive, going into the theory of operation for the oscillator circuit. The 40 microamp meter movement is described in such detail as to permit field repair and rewinding of the meter coil. A section is devoted to the variation of readings due to changes in ambient temperature, battery voltage, meter position, and the frequency of ac voltages. All measurements are illustrated by simple one function drawings. It was evident that the manufacturer realizes his instruments will be used in a wide range of climates by people who may not be too well trained.

The U-4341 is a combination instrument that incorporates a transistor tester with a high quality conventional VOM. It is a quality instrument that would be classed as a bench test instrument adequate for commercial service work. It is housed in a black plastic case designed for tabletop use. Rated accuracy is 2.5% for dc and 4% for ac ranges. Ac frequency response is from 45 Hz to 20 kHz. Both ac and dc currents are measurable. The instruction book is very comprehensive and, like the one for the U-4323, provides a lot of information for the user working in out-of-the-way places.

Another nice feature is the inclusion of special low range scales. The lowest ac current range is 300 microamps, dc is 60 microamps. The lowest dc voltage range is 300 millivolts full scale. The most interesting feature is the built-in transistor testing circuit. The meter will measure Icb, Ieb, and Ici (defined as initial collector current as measured in the common emitter configuration with zero emitter-base voltage) with an accuracy of ± 2.5%.

The quality of the instruments is quite good when the price class is considered. Both instruments are well sealed against dust and moisture. Battery replacement is accomplished by removing the back plates. All instruments have manufacturing seals placed by their quality control department to reveal any tampering that might void the warranty. A separate certificate of inspection giving the performance specifications and quality assurance signoff is packed with each instrument.



The U-4341 has a neat straightforward panel layout. Note the universal transistor socket at the top.

Reading the manufacturer's literature provided insight into the type of equipment available to the Soviet ham. There appears to be no production of strictly amateur radio equipment in the Soviet Union at this time. This means that the Soviet ham has to build his own or modify military surplus equipment. This is made available to him through DOSAFF, an organization that has no American equivalent. It is a civilian auxiliary for supporting the armed forces, and would be roughly analagous to having MARS, civil defense, the National Rifle Association, sport parachuting, and other paramilitary activities rolled into one super organization. Soviet defense policy places significant emphasis on having a trained cadre of civilian radio operators available to assist the military in the event of war, so they supply individuals and clubs with equipment much in the manner that our MARS program is supposed to operate.

In browsing through their equipment catalogs, I came across a number of test instruments that would be of interest to hams in this country. Among these was a neat little 3 inch scope. It had a calibrated triggered sweep, 10 MHz bandwidth, built-in calibration, and a number of other desirable features. Again, there was a design twist — this scope was designed for the hobbyist with limited facilities to maintain his test equipment. Although of recent design, it was designed around a series of high reliability vacuum tubes to minimize the number of components.

If and when these products appear on our market will depend on the political situation. One of the major stumbling blocks is the lack of a "most favored nation" treaty with the Soviet Union. Lack of such a treaty results in drastically higher import duties that would price the products out of the market. There has been a great improvement in relations between our two countries in the past few years. Hopefully this will continue so that we will avoid blasting each other off the face of the earth! With the ever-increasing prices of Japanese electronics, we may see a day when the USSR will be a major supplier of popular electronic equipment. ■

Surplus Goodies Are Still Around

- - what to look for

Almost everyone in electronics makes liberal use of surplus material, not only because of the price advantage, but also because there are a number of surplus items which aren't generally available in ordinary stores. In the past, most surplus outlets dealt primarily in radio equipment, with a certain amount of radar components and maybe an occasional computer unit turning up. In those amazingly remote days before solid state electronics and computer technology, the surplus buyer could identify just about anything he might run across, and if he couldn't, the man who ran the place could look it up.

All that has changed, for better or worse. Browse around a surplus store today and you'll be lucky to recognize half the stock; even the store's owner will often throw up his hands in a "you've got me" gesture. The new space age technologies have spawned a flood of incomprehensible components that tend to pile up in the back room simply because nobody really knows what they are.

It's a real shame that more people don't know, or don't care, about these unknowns, because they're *good*. For one thing, they are often a step ahead of state-of-the-art, utilizing principles that commercial products haven't gotten around to yet. Microwave technology in particular has entered the twenty-first century, and much aerospace surplus involves microwaves. They are generally built to incredibly high standards, especially if they come from NASA; some of those components make the proverbial Swiss watch look like a dime-store can opener. Finally, and most importantly, they are cheap compared to the usual surplus fare. A few cautious purchases can yield a small fortune in cannibalized parts alone, and if luck is with you, you might walk away with a fine UHF amplifier for the price of a bag of capacitors.

So how do you figure out what is good, or even what something is? While there isn't any cut-and-dried method, there are a few rules of thumb that can help turn surplus shopping into a real treasure hunt.

Suppose you have, while browsing through your local surplus emporium, come upon a whatsit that looks interesting. After checking it for identifying marks and finding none, you take it up to the cash register, where the man says he doesn't have any idea what it is, but you can have it for five bucks. Should you get it? After all, five dollars in these days is rich food for a junk box stuffer.

The first thing to look at is the provision for input and output. This might likely be in the form of plugs, sockets, or waveguide flanges. The number and type of connectors can tell you a lot about the unit. If there are a good many plug-in contacts and no waveguide, there's a good chance you've got some kind of logic device. If there is one or more BNC connector, expect high frequency circuitry. If there are waveguides but no wires or plugs, don't bother with it unless you like to work with waveguides, because you won't find anything else inside. If there are waveguides and electrical connectors, then you might have an amplifier or oscillator. If there are very small coax connectors, you probably don't want it, since the odds are it is a stripline unit, and that whole field is generally outside the reach of a hobbyist.

Next look for identifiable parts. A sticker reading "Danger, Magnetic Material," or the like will usually be affixed to a magnetron or traveling wave tube. In addition, the latter, of which there are a bewildering variety, are often relatively long and thin metal tubes. If you see waveguide involved with gearing or other mechanical linkages, expect a tunable cavity, which might indicate an oscillator or measuring device. A rotating cylinder or drum with movable pins or tabs might be a programming unit.

If, after examining the device, you decide to buy it, don't forget to make the same checks you would for a conventional component. Look for evidence of water soaking or heat discoloration, not to mention dents and other physical damage. Remember that even the rarest find isn't worth a cent if it's broken.

After you get your treasure home, you'll probably want to delve around in its insides. One word of caution: Some microwave tubes use a very poisonous beryllia ceramic inside. They are usually marked with a warning, but to be on the safe side, don't open anything that looks like a traveling wave tube, even though there may be some very inviting setscrews on the end. Even a few

particles of beryllia can cause cancer if inhaled. There is also a slim but real possibility of radioactives being used in some aerospace equipment. Any component containing even a slight radiation source will be marked with the purple trefoil. If you see it, it might be prudent to return the unit to the store; you certainly won't have a use for it.

The odds are against finding either of those things. Probably you'll uncover some conventional PC boards with conventional, high quality components on them, various waveguide devices, and perhaps some stripline units. These latter will probably be slim metal boxes, anywhere from one to five inches square. Inside the boxes you're likely to find only conductors and junctions. If you're very lucky, you'll recognize the innards of your buy as a whole unit, say an amplifier, and be able to use it as is. If you're very unlucky, you'll find all the circuitry encapsulated in cement, or incomprehensible stripline boxes, or something you still can't identify. In between these extremes, you'll find some good usable parts or some that may be usable someday — junk box stuffers.

If you can find a manufacturer's name and a model number, you might try writing for information. Some manufacturers are very helpful, some are not so helpful, and some are helpful but charge for spec sheets. Remember that an SASE is always called for.

With a little practice, anyone can come up with other rules of thumb, taking into consideration size, materials of construction, and geometry. But if you do buy something that neither examination nor requests can identify, don't feel too bad. Someday you may see that gold-plated, waveguide-studded, epoxy-potted treasure in a catalog for fifty dollars. And if you don't, it will still make a fine bookend. ■

The Touchtone Connection

-- quick mod for the Standard HT

Two years ago I installed an older version Data Signal touchtone pad on a Standard. It was very difficult due to the thick metal I had to cut through in addition to the plastic thickness. It was hard to take out of the carrying case, but the alternative was to cut an opening in the case. This idea I rejected, since I thought it would ruin the appearance of the case. Since convenience is the main purpose of having a handie-talkie, I was pleased to discover that Data Signal's newest touchtone pad (TTP) is only .050 inches thick and made of a mylar-covered mask with stainless steel wells and gold-plated circuits. With this pad there is no need to cut the carrying case at all, giving the project a more professional look. I recently purchased a new Standard HT and installed the new trim TTP. I found that I could operate the new keyboard (KBD) with the HT inside its case. Those who may not be able to or want to do this will be glad to know you can apply a "peel and stick" facsimile of the TTP on the leather case directly over the actual TTP on the HT. I was lucky enough to acquire a "peel and stick" mask of the KBD from Data Signal which is located here in town. Now I will do my best to explain the installation of the TTP and give you some of the reasons I think it is a good idea.

This time I decided to place the TTP very low on the front panel of the HT. I chose this position because all you have to cut through here is plastic, and this placement looks best. Here are some things needed for the project other than the HT: Data Signal TTP kit*; file — very small; electrician's knife; two base, clear epoxy; masking tape; soldering iron and solder.

Remove all knobs and the main PC board from the chassis. Lay the TTP circuit board on the inside front for approximate final placement. Check for fitting and then install the crystal near the top as close as possible to the TTP circuit board. Lay some sort of insulation tape on the metal sub-chassis and then solder the wires to the circuit board. Care should be taken not to get solder in the holes on the bottom of the KBD. Now solder the other wires to the TTP circuit board. Next place tape over the circuit board to insulate it from the HT's main board. The extra wires should be taped down too. Three wires are run to the right side of the HT up to the PL socket where #1 is "ground," #3 is "power on transmit" and #8 is "external audio input." The leads are tinned and stuck in the socket. Also, a 50k helipot is used here to control the audio into the HT. The center wiper arm on the trimpot is the audio input from the encoder, and one lead should go to ground and the other lead to #8 PL socket.

The pad is glued firmly on the HT with epoxy. This must be used sparingly and with much caution not to allow the epoxy to get into the holes on the bottom of the KBD. These are for breathing. Allow the pad to conform to the curvature of the HT as the KBD is flexible. After gluing the KBD on the HT, tape it down with masking tape and let it stand overnight until glue is completely dry.

Try to put the HT into your desk top charger if it fits without pressing on the KBD. If not, take the knife and cut the ribs out of the inside of the charger. Then file this area down to a smooth finish.

I hope others will enjoy this project as much as I did. I think this is by far the easiest TTP arrangement and most professional-looking installation for the Standard HT. ■

Build A Phone Exchange

-- using dial telephones

The telephone is one of the most useful devices available for communicating around the house, farm, or place of business. Unfortunately, most of us are usually forced to either rent equipment from the local telco, which can be rather expensive, or settle for war surplus magneto phones. There is another solution, however – that is, to construct your own dial telephone system.

This may seem to be an awesome project for many; however, the exchange doesn't have to be a ten thousand line crossbar unit with push-button dialing. A simple but efficient switching system can be built at reasonable cost, and with only a few hours work. In order to keep the cost minimal, and the construction simple, we are going to forego some of Ma Bell's luxuries, which are really unnecessary anyway. What we will be left with is a streamlined version of a commercial telephone exchange which will be best suited for private use.

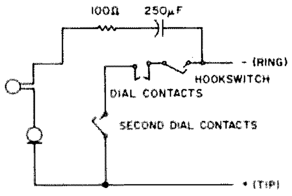

Fig. 1.

The theory behind our exchange is basically the same as with commercial systems, that is, circuits to distinguish between on and off hook conditions, supply talk voltage, count the impulses from the dial and make necessary selections, and provide a way to apply ringing current to the desired bell. In most commercial exchanges, the talk voltage used is 48-50 volts dc, while the ringing current is 90-105 volts ac, at frequencies between 20 and 50 Hz.

Most commercial switching equipment also operates from the talk voltage. In the majority of professional systems, the ringing current is obtained from motor-driven ringing machines, or from static ringing generators. In our exchange, we will use 26 V dc for talk, and steal the 110 V house current for ringing the bells. Most telephone ringers will operate satisfactorily at this higher frequency with only minor adjustments. This is really the easiest method of ringing – as you do not have to change the bells in your phones. We will also make use of the three wire system – that is, three conductors leading to each subset. This alleviates the need for more sophisticated equipment, and saves on expense.

In general, our switching system operates using the following pattern: All telephones in the system are connected to the exchange at the terminal block. There are three conductors per station, which are broken down to color codes red, green, and yellow. The red and green wires of all stations are interconnected in parallel with the dc power supply, with the positive going to red, and the negative to ground. The yellow leads are separated – and given their own terminals. The talk circuit and the dial impulses use pair red-green, while the 110 V ac ringing current goes over conductors yellow (+) and green.

In series with the dc power source is the line relay – which responds to the off-hook condition, and also relays dial impulses to the connector. I chose to have the uniselector powered directly by the 110, although this is not mandatory. The uniselector coil voltage is controlled by the line relay. When a telephone is lifted from its rest, the line relay closes, and provides talk voltage. At the same time, it causes the uniselector to advance one step, which is the "start" position. Additional pulses will drive the stepper until it rests on the desired contacts – causing the 110 V to be applied to the yellow ring line.

Our exchange makes use of the common talk-selective ring principle, which is very economical for low use applications. There is no need for a busy signal in this system, as you can tell immediately upon lifting the handset if the system is being used.

Due to the fact that our system uses a three conductor wiring plan, it may be necessary to alter the connections at the subset. In my exchange, I use imported

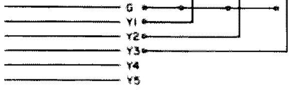

Fig. 2.

Ericsson-type telephones, which are intended for use with either two or three wire systems. No modification is required. Also, the European telephones have high frequency "straight line" ringers which do not need retuning. Other types of telephone sets will operate equally as well, but, as mentioned earlier, it may be necessary to retune the ringer. This may be accomplished simply by adjusting or removing the weighted striker, or experimenting with the screw settings.

If the telephone is of the type which is normally intended for use with standard U.S. two-wire networks, you may have to change around some of the wires on the phone's transmission network, so that the ringer will be connected to both yellow and green. There will be no problem with the talk circuit – just remember that the conductor codes are red and green for this, and that green is shared with ring.

It is also possible to rewire the telephones so that the receiver element will buzz loudly instead of having the bell ring. This would only occur while the telephone was on the hook, and the receiver would be used for regular speech upon being lifted. Fig. 1 gives you a representative schematic for "receiver ringing."

With regard to the types of wire and cable used for connection, I used eight conductor cable leading to the subsets, with three conductor cable tapped into it where needed. In order to save on wire, I used one pair as the talk circuit for all stations, but gave each station its own ringing line. This practice is illustrated in Fig. 2. I would definitely recommend that terminal blocks be used at the subsets, if possible. This is only good wiring practice, and saves a lot of grief. With our mini-exchange, I do not really recommend that this be done, as speech quality is diminished greatly. For best results, use metallic paths on all circuits. Remember that you are using 110 V ac for ringing, and make certain that all wiring is suitable for carrying this.

I should mention that the speech quality of your exchange will depend to a great degree upon the wiring job. That is to say, loose connections and this sort of thing will cause scratchy, almost unintelligible circuits. Also, the type of dc power supply used will play a great part in the speech quality. There will be some noise from the ac parts of the exchange, and the moving parts, but this should not impair conversation.

In my exchange, a ringing signal may be heard in the receiver; this is derived from the 60 Hz hum present on the line when the uniselector is connected with it. As was previously mentioned, there is no need for a busy signal.

Before you start construction of your own exchange, you should plan carefully in order to determine your telephone needs. The basic exchange circuit is intended to take care of ten numbers, or telephones, although with modification more could be used. It would be helpful if you had the telephones which you will use in the system on hand during construction.

Building the exchange is really a "trial and error" process; that is to say, you build a stage, test it, and hook a couple of stages together to see if it will all work properly. As you build your exchange, you may find certain modifications which will better suit your needs. This project is of the type that lends itself to further experimentation.

Now that we have discussed the theory and applications of our exchange, we can venture into the construction end of the project. You will notice that there are but a few parts used in the system, all of which can be obtained without much difficulty. It is important, however, to use a uniselector (stepping switch) which has ten positions, with automatic reset. The counting operations in this exchange are on a decimal basis, and therefore it is important that the counter correspond likewise. There are many different types of steppers available, but I have found that the only one usable in our system is the unit with ten positions.

The inexpensive 25 position uniselectors which flood the market are generally not used as connectors, but are employed in the line-finder stages of commercial exchanges. Other than this note on the counter, components may be as varied as need be. Most of the exchange can be put together from junk box parts.

Construction itself is remarkably simple; just use good wiring techniques, as you would with any project. The components used in the exchange are rugged, and will take lots of abuse. I have never had to replace a single part in the three years since I built the unit. Another thing to remember when assembling the exchange is that the green wire serves as a common ground, and must be connected to all areas requiring low voltage negative. If you have problems with the phones not ringing, I would check the green wire to make sure that it links all stages of the system.

When you are ready to wire the uniselector, choose the station numbers using digits two through ten. This system uses digit one as a starting point, and the line relay automatically sends the connector to this point. Also, if digit one were used, jiggling the hookswitch could accidentally call a station. Fig. 3 gives you the complete schematic for the exchange.

Once you have completed wiring the exchange, you should test it, looking for possible short circuits and connections which might rub against each other. This is especially necessary at the

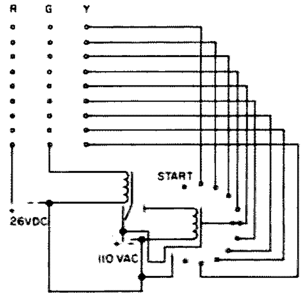

Fig. 3.

uniselector. Make sure that the correct voltages are reaching the subsets – and that the talk circuit uses red-green, and ring has yellow-green. Accidental reversal of these color codes could result in your telephones being damaged.

With the automatic reset, the uniselector should return to the rest position when you hang the phone up. Some adjustment of the stepper may be necessary. Again, trial and error adjustments will be required from each exchange. I have used phones up to a half mile from the exchange without appreciable loss in transmission volume or ringing. This system is quite flexible in its uses, and provides much for very little money.

The characteristics of operation are as follows: On picking up the handset, the line relay closes and a dc hum may be heard in the receiver. The uniselector has also stepped to its first position, and is ready for your instructions. When you dial, the stepping switch moves forward in synchrony with your dial pulses. Immediately at the end of the pulse train, 110 V ac is connected to the bell of the called telephone and it rings. The ringing will continue until the called party answers, or until you hang up your telephone.

This telephone system *should not* be interconnected with any commercial systems, as the dc from your exchange will cause problems for the switching equipment at the telco, and perhaps give you a chance to meet some of Ma Bell's attorneys. ■

Build A Brute Power Supply

-- completely regulated and protected

Tom Lawrence WB4QLW
P.O. Box 3524
Danville VA 24541

Having recently purchased a new solid state 80 through 10 meter transceiver, I couldn't bring myself to lay down some additional long green for a +12 V dc power supply. Check the prices and you will see what I mean. So I got busy and looked through stacks of my ham magazines to find a supply that would suit my purpose. That is, +12 to +15 V dc at about 20 Amps intermittent and 9 to 11 Amps constant current that is well regulated. I had built one such supply last year for my 2 meter amplifier which was good for about 8 Amps. This was an article in *73 Magazine* by Warren MacDowell in the May, 1975, edition. I would suggest to anyone desiring to build this type of power supply to read that article whether or not you are going to build that supply or some other, as it contains some very good technical information laid down at ground level.

While having no problems with the circuit, I did have trouble finding the parts locally. What I ended up with was not as attractive as the one pictured, but it did a great job and still does. All of the parts on the regulator board are very easy to find if you substitute ½ Watt resistors for the ¼ Watt ones. Radio Shack and Lafayette seem to keep an ample supply. The same with the LM723 chip. I could not, however, find the MJ3000 Darlington anywhere locally. Good high current pass transistors will work as well as the Darlington for this purpose, and I might add that that is what we use in our computer power supplies for the most stable operation. The best you can get is the 2N3055 or equivalent, as they are less susceptible to going haywire with some rf feedback. You can drive 4 of these goodies with a single 2N4911 or equivalent and, by putting .3 Ohm resistors on the emitters of the 2N3055s, you can safely draw up to 25 Amps of current at +13.8 V dc intermittent and about 18 Amps continuous (that is, provided you heat sink all 5 transistors, driver and pass).

I used two 15,000 uF capacitors for better regulation, but they don't have to

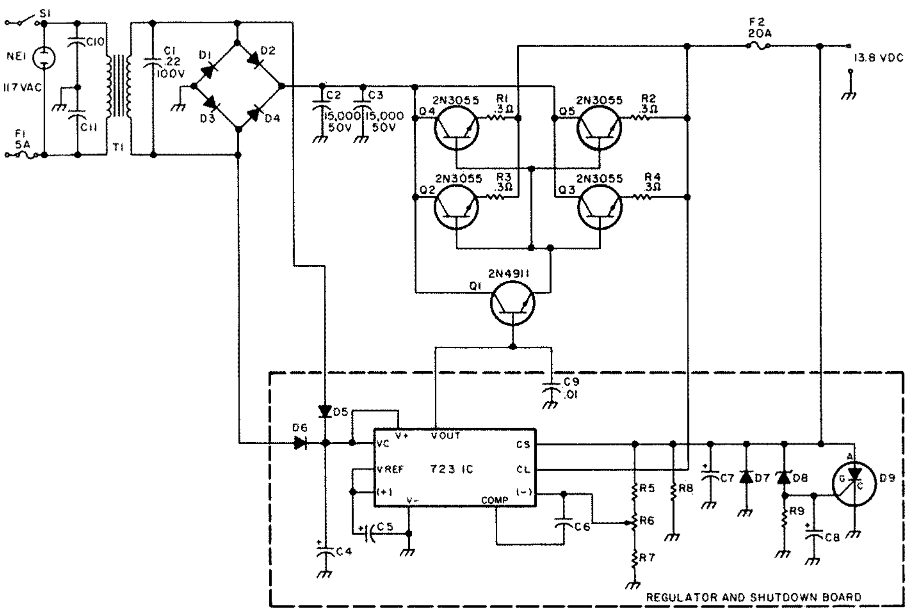

Fig. 1.

be two of that exact value. You can use what you can find and, as long as they total up to between 25k and 30k uF, you will be OK. The voltage ratings should be at least 40 V dc and 50 V dc surge.

I had a couple of old TV transformers around and I put them in series to get about 19 V ac; with a bridge rectifier and all the capacity, I had my 25 V ac for good regulation. One of the transformers had a single 6.3 winding at about 8 Amps and the other had both a 6.3 winding and a 5.0 winding both rated at 7.5 Amps. This works out fine, but I was able to find a single transformer at a hamfest with the secondary rated at 25 V ac at 12 Amps; it works very nicely.

Some other things I did differently were:

(1) Fuse both the input and output of the supply for 100% protection.

(2) Put .01 uF caps across the primary of the transformer to ground for good transient protection.

(3) Put a .22 uF non-electrolytic tubular capacitor rated at 100 volts across the secondary and bridge rectifier to aid in noise and rf.

(4) Put a .01 uF disc capacitor on the output of the voltage regulator terminal Vo to bypass noise that will be passed through the output transistors (incidentally, this shows up as sounding similar to ac hum if you have an FM rig connected to the supply, and it gives you an echo on your voice on SSB peaks).

(5) The last change that I made I feel is by far the best. I have a 15 volt zener diode constantly monitoring the output voltage. If anything happens and the voltage exceeds 15 volts, the zener conducts and fires the SCR and immediately crowbars the supply from the transceiver. It is extremely dangerous to solid state transceivers (any band) for the input voltage to exceed 15 volts. The 5 volt and 8 volt regulators in the rigs will not take it and you will fry one very easily. When the voltage does exceed +15 volts and the crowbar shuts it down, what has probably happened is that the regulator chip and the high speed diodes are blown for some reason, and by not permitting the 2N4911, your pass transistors will be saved. A parts layout is not shown, as it really is a simple circuit that can be etched or point-to-point wired easily, and again you can refer to the past article. ■

Parts List

R1-R4	.3 Ohm 10 Watt
R5	1.8k ½ Watt 10%
R6	2.5k trimpot
R7	2.7k ½ Watt 10%
R8	1.5k ½ Watt 10%
R9	1k ½ Watt 10%
C2-C3	15,000 uF 40 V dc
C1	.22 uF @100 V dc tubular
C4	250 uF @25 V dc
C5-C6	1.2 uF @35 V dc tantalum
C7	220 pF @25 V dc
C8	100 uF @25 V dc
C9-C11	.01 uF @500 volts
D1-D4	1N3492 or equiv. (100 piv @ 18 Amps)
D5-D6	1N4607 or equiv.
D7	1N4002 or equiv.
D8	1N965A or equiv. (15 volt zener)
D9	2N4441 or equiv.
Q1	2N4911 or equiv.
Q2-Q5	2N3055 or equiv.
F1	5 Amp fast blow fuse @ 125 volts
F2	20 Amp fast below fuse @ 125 volts
NE1	115 V ac neon indicator lamp
S1	Switch — single pole, single throw @ 115 V ac

Drake Touchtone Review

-- dial as you drive

One of the most useful accessories for your 2m FM rig is a touchtone™ pad for use while operating mobile. A lot of repeater groups have installed touchtone functions ranging from telephone dialing to direct weather reports. Recently, the Drake Company introduced a new mike with a built-in touchtone pad that should be of considerable interest to many amateurs. The mike is specifically designed for use with the Drake TR-33, but can be used with other gear that is compatible with a 500 Ohm, dynamic microphone.

The feature that makes the Drake mike so interesting is that you can turn it over and tap out a telephone number from your car. What's more, the physical dimensions are only 6.6 x 8.9 x 4.3 cm (2.6" x 3.5" x 1.7"), which makes it just about the same size as a regular microphone.

The Model 1525 specifications are pretty impressive. The frequency response is 300-5000 Hz. The encoder audio level is internally adjustable from 1 mV to 5 mV and is factory adjusted for Drake gear. Finally, the supply voltage requirements are 7.5 to 15 V dc.

After receiving the mike, I had to rewire the panel socket on my Drake TR-22C. The adjustments took about one hour and involved providing the necessary voltage to pin number 4 of the panel jack along with relocating a ground connection. On a TR-33 no rework is required; just plug in and it is ready to go.

On-the-air performance has met all of my expectations. The audio quality has been found to be comparable to the original mike. The tones were tested and found to be on the correct frequency and at the proper level. I had no trouble accessing my local repeater on the first try.

The mike has interested a number of local amateurs who want a microphone and touchtone combination but don't want to build a kit. At $49.95, I think that Drake has a real winner. ■

Marine Radiotelephone Conversion

-- remember the 80-D?

Photos by K8LKC.

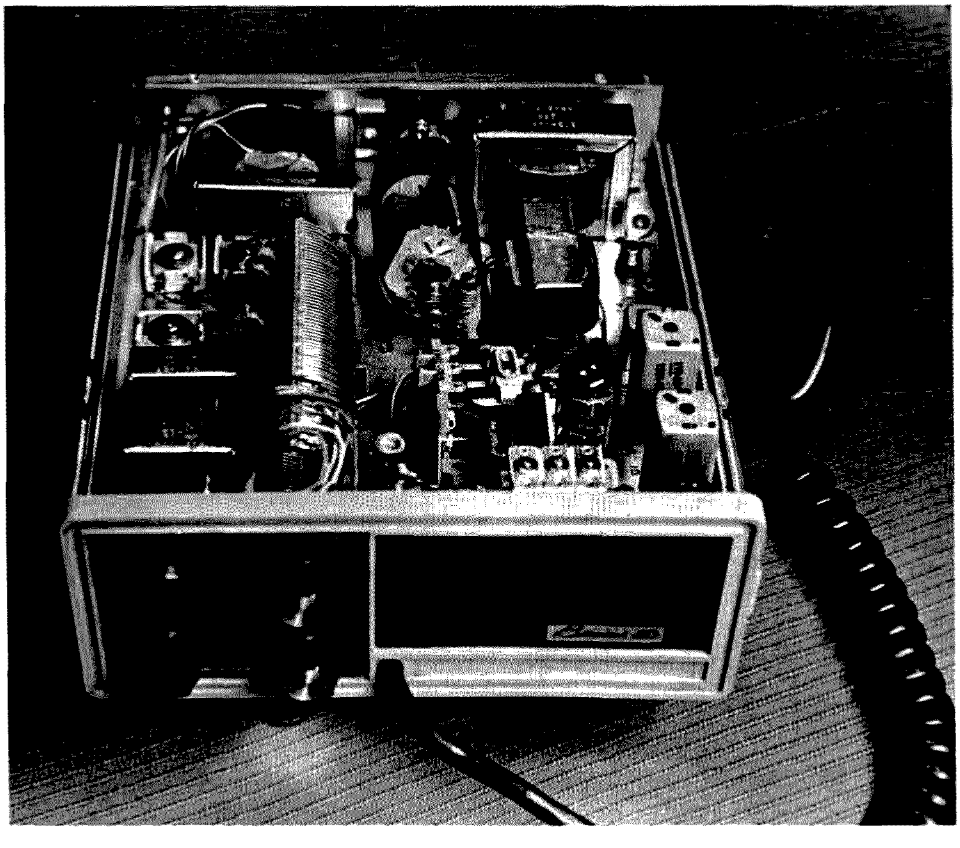

Fig. 1. The author's BIMINI 30 with top cover removed. This 30 Watt three channel model is one of several Pearce-Simpson AM marine radio telephones.

Would you believe a 50 Watt AM transceiver for 160 or 75 meters – or a CW transmitter – or a 12 to 375 V dc solid state inverter – or a dandy collection of parts for your junk box – for $20 more or less? Hard to believe in this age of inflation, but read on . . .

This year marked the end of AM operation on the 2 MHz marine band (which includes that venerable 2182 kHz calling and distress channel) in the U.S., with marine radio shifting to their new VHF FM band. Boat owners now find their AM radio telephones useless and may junk them if a ham doesn't get there first! Some rigs have already been deep sixed, so you had better act fast if you want one.

This article is based on my experience with Pearce-Simpson units used by many pleasure and business boaters on the Great Lakes. They are similar in size to 2m FM transceivers, designed for 12 V dc and draw half an Amp on receive and up to 17 Amps on transmit. The receivers are

olid state except for the f/converter stage which is a ube for protection against tatic picked up by the tall boat antenna. The trans- itters are two tube oscil- ator-power amplifier type sing a 12JB6 final with a olid state modulator and run 5-50 Watts input power with late modulation.

Both transmitter and eceiver are crystal controlled nd FT-243 holders work ine. The receive crystal is 455 kHz above the desired requency. Various models ave three to five channels, nd some include a standard broadcast receiver. A switch llows monitoring with trans- itter filaments off to save power. You may find a carbon push-to-talk micro- phone or telephone type nandset. A pilot lamp ndicates relative rf output ("tune for maximum bril- iance") and a 0.635 cm (¼ nch) phone jack is on the back for checking final cathode current.

The transmitter output circuit is a pi-network plus a arge loading coil in series with the antenna terminal, designed to load short vertical tennas below their resonant requency. (A typical boat tenna is a vertical mast about 6 meters high with at ast its upper half being a helical coil.)

The channel switch not only selects the receive and ansmit crystals, but also elects individual plate tuning capacitors and taps on the plate and loading coils for each channel. Thus all tuning preset. Some models have a front panel rotary switch connected to the first twelve urns of the loading coil for a ine tuning adjustment.

Most of the wiring is point-to-point and easily raced if you can't get a chematic. The channel election wiring to the crystal ockets, tuning capacitors and coil taps is all color coded Ch. 1 is brown, 2 is red, 3 is orange, 4 is yellow ... cognize that code?). Some units have the receiver i-f and

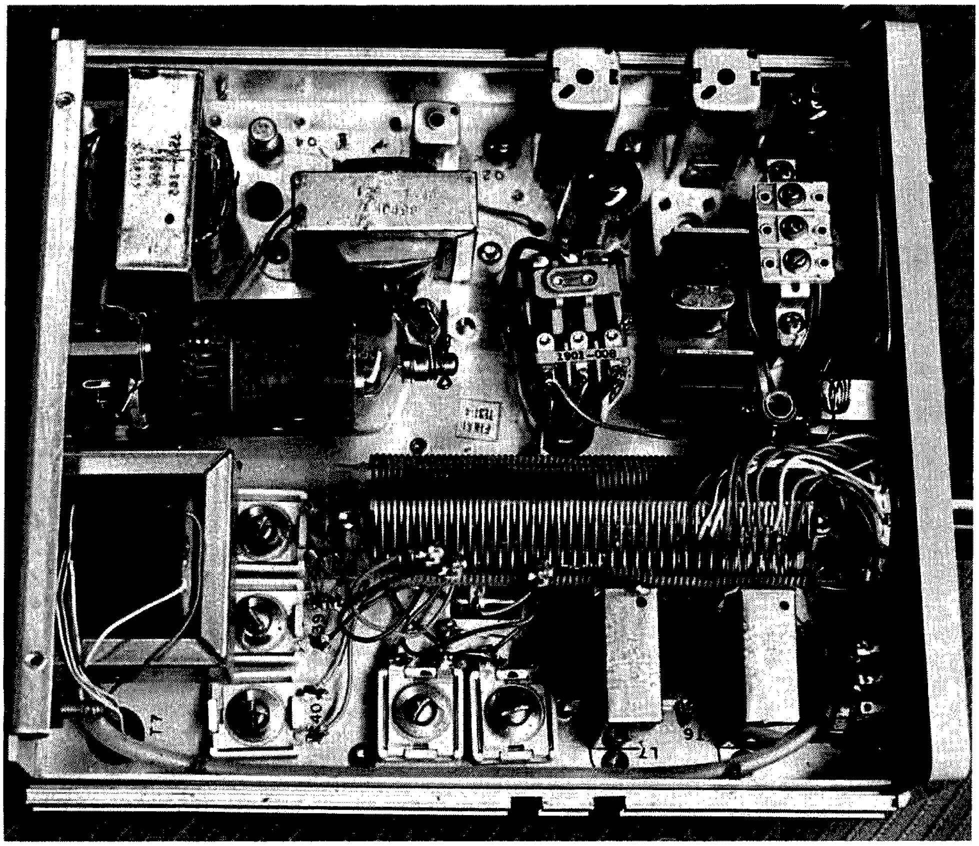

Fig. 2. Top chassis view of the BIMINI 30. The compression capacitors C38, 39 and 40 are the plate tuning capacitors for the three channels. The paralleled antenna loading capacitors are seen at the lower center with the series antenna loading coil above them. A ferrite bar inside the coil increases its inductance. The receiver section is along the top of the picture with the receiver's rf trimmers mounted above the speaker. From left to right across the center of the picture are the 12JB6 final, T-R relay, crystal sockets, receiver converter coil and the rf output indicating lamp assembly.

audio on a circuit board.

No Modification Needed

Now – how can we use these rigs? For openers, just change crystals, retune, and you are all set for 160 meter AM, base or mobile. If you use a car battery for your 2m FM rig in your shack, you are all set for power – just charge it more often! These rigs are great for party line operation with your friends. Here in the Kalamazoo area, we use 1985 kHz and reduce the power to 25 Watts (the maximum nighttime power for this segment in Michigan). Even with modest antennas we can reach several states and have even heard complaints from a tight-knit group in zero-land for using "their" frequency!

Best results will be obtained with a vertical antenna (top or continuously loaded) with plenty of radial ground wires. Check various antenna books for more information. However, a single wire not exceeding one quarter wavelength and run as vertical as possible will load and work over short distances. If your lowband dipole has a parallel conductor feedline, just tie the two conductors together and use it as your antenna. The ground system is very important. Use several ground rods connected together or a water pipe if you have nothing better, and keep the effective ground lead as short as possible. In technical terms, the antenna load must have low resistance and any reactance present must be capacitive to be loaded with the original tuning setup. Other loads would require external tuning devices.

Heat Up Your Soldering Iron

Now for some easy modifications. Like CW? Disconnect the +12 V dc feed to the modulator, short the modulation transformer secondary and plug a key in the meter jack. Remember this old-fashioned cathode keying method puts the B+ on your key when it is up! You can build a simple 455 kHz BFO for the receiver.

How about 80 meter CW? Use a receive crystal 455 kHz below the desired frequency and open the receiver trimmer capacitor. Some of the original receive crystals may be usable here; just add 455 kHz to the crystal frequency and see if it is in the band. Use an 80 meter transmit crystal and tap up on the plate coil.

Don't like crystals? Build a simple vfo.

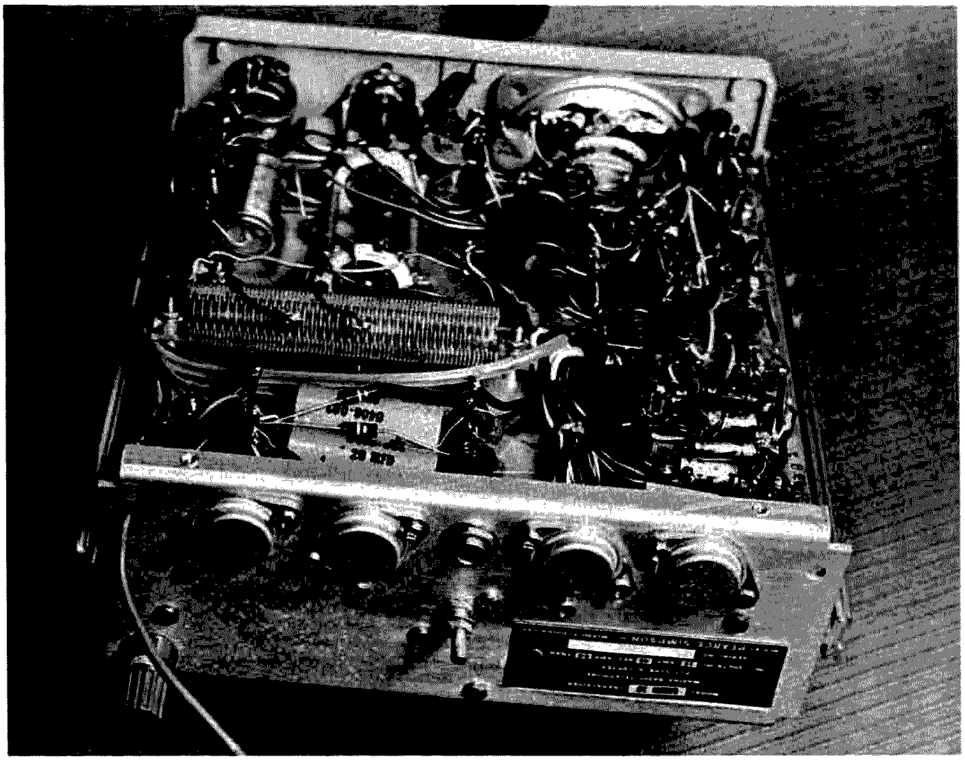

Fig. 3. Rear and bottom view of the BIMINI 30. From left to right across the rear panel are the modulator transistors, meter jack, B+ inverter transistors, 12 V dc lead and the antenna binding post. The final plate coil is seen beneath the chassis across the end of the channel selection switch.

Still not satisfied? Remove everything except the B+ inverter and build whatever you like!

Where To Find Them

See your boating friends or marine radio dealer. While bargaining, remember that AM on the 2 MHz band is of no further use to the boater. While you are at it, try to get the HF boat antenna. It makes a good vertical if you put some ground radials under it. Don't wait, however – these rigs may not be kept by their owners very long.

If you cannot find a rig locally, send an SASE for information on what I have available or know about. A dollar will bring you copies of schematics, tuning procedures and other information. I would also be interested in hearing about your experiences with these little gems. Please mail all requests for information to PO Box 2664, Kalamazoo MI 49003. ■

Solder Soldier

- - sniff your heart out

Here is a handy gadget for picking up solder from a printed circuit board when you are trying to remove a component or excess solder. There are commercial solder removers available for about five dollars that are easier to use, but unless you need one quite often, this one works fine.

The large end is turned on a lathe to fit inside the metal tube on the end of the XYL's vacuum cleaner hose. A bit of plastic electrician's tape will hold it there.

When you are ready to remove the solder, put the tip near the solder and melt it with the iron. Put your finger over the 3/8" hole and the suction will remove most of the solder. If the solder sticks to the inside of the 3/16" hole, you can dislodge it with a nail.

The material was teflon, but you can use any plastic that will not melt if you accidentally touch it with your iron. ■

When the Lights Go Out

-- prepare yourself

There is always a "hurricane season" in the future, so it is never too early to consider proper preparations.

Persons who have experienced severe hurricanes have greater respect for the threat, and more generally comply with warnings and evacuation advisories. A survey immediately following Hurricane Camille (1969) found that those who evacuated comprehended the danger of a storm surge much better than did those who stayed behind.

It is difficult to comprehend the magnitude of a hurricane disaster without having had personal experience with disasters. The "voices with experience" are strangely ignored, and the volumes of statistics and warnings do not "sink in."

As the years increase since the last major hurricane, respect for the storm and the flooding grows more dim. The influx of people into the area who have no personal experience of hurricanes further dilutes the "voice of experience," and warnings now fall on "deaf ears."

More disturbing is an emerging pattern which suggests that our society is fast losing its resilience and its ability to deal with the long-term dislocations and frustrations of a natural catastrophe.

This is demonstrated in the sharp increases in alcoholism, anxiety, depression, and other emotional problems following recent natural disasters across the nation, and around the world. We are facing a mental health crisis.

This spreading pattern of maladaption to disasters, and the ignoring of potential disasters, is spreading like a cancer across the face and mentality of the nation.

What can be done to prepare the community and nation to meet widespread natural disasters? We know natural disasters are on the increase – earthquakes, tornadoes, floods, landslides, blizzards, hurricanes. One of these, as a major disaster, will strike in our community within the next few years.

We are getting better at predicting certain disasters, and hurricanes are the most accurately predicted and followed of any natural disaster. But does this prediction help? If we do not study and understand proper preparation and planning, all the warnings and predictions are useless.

A policy of maximal information, and responsible and visible community leadership, is a top priority item. Without appropriate leadership, our disaster preparations themselves will be a disaster. The role of radio amateurs is generally not that of "leader," but that of "communicator for leaders."

Home preparation must be integrated with community preparation, and community preparation must be coordinated with society as a whole. Mental preparation is even more essential than physical preparation if we are to survive as a society when the next major disaster strikes.

Perhaps the two greatest factors to produce casualties in a disaster are inertia, both individual and governmental, and the mental attitude of "if we ignore it, it will go away," and "it won't happen here."

Disaster planning in its current stage of development to a large extent is based upon civil defense plans for nuclear attack, or a minor modification of these plans. This type of planning, and thinking, is diametrically the opposite of planning for natural disasters.

Plans for nuclear attack preparedness assume that outside help would not be available (because the whole country would be stricken) and evacuation would not be feasible. Natural disasters are rather localized, and outside help would be available if planned for properly; evacuation before and after a natural disaster is feasible if there are places nearby that are not affected by the disaster.

A recent survey (1971) following a natural disaster issued a set of six recommendations for local government agencies. Some of these recommendations could apply to amateur radio, and to us individually.

1. *Local governments should establish emergency operating centers in the event of a serious disaster.* These should not only be established, but also thoroughly tested periodically. Who will man the center? How will the families be cared for if a person is at the center?

2. *Local governments should ensure the existence of emergency communications for any foreseeable emergency.* Without "eyes and ears" to gather information, and without a "voice" to communicate with sources of help, the emergency coordinating center is dead. These lines of communication should also be tested periodically.

3. *Local governments should evaluate and update plans, procedures, and preparedness measures.* An extension of this would be that these plans and procedures should be conveyed to the public in adequate time; don't wait until a disaster strikes before informing the public what to do.

4. *Provisions should be made to improve interjurisdictional coordination in future disasters.* This is a big problem in many areas, with each jealous jurisdiction wanting to do it "his way," or he won't cooperate with the other jurisdictions. We must all work together to help one another, and, with knowledge and forethought, make area plans. A hurricane, for example, does not strike an isolated jurisdiction and stop at the boundaries of that

jurisdiction, but affects a wide area and knows no political boundaries.

5. *Officials should develop a country-wide emergency transportation plan.*

6. *A study should be undertaken to ascertain the best disaster communication system.*

What can we as radio amateurs do to prepare for a disaster, and to aid in a disaster? One of the mandates of amateur radio is to be a source of communications in case of disaster or emergency.

Our area of competency is communications, particularly during and after a disaster. Before a disaster, commercial radio and TV, we assume, adequately communicate with the public, and public service radio is adequate. During and immediately after a disaster, much of the "eyes, ears, and voice" of the community will have been lost. Amateur radio will have to step in with mobile and portable communications to fill this loss of the other services.

What can we as amateurs do to prepare for and meet our obligations? (Incidentally, in making our preparations, we also improve our own mental attitude, which in turn helps the community.)

Two basic areas of preparation must be considered — our communications equipment, and how we are going to live in the disaster area.

We must assume we will have to bring our equipment, including power, and our food and lodging from outside the disaster area into the area. We should be "self-contained" to operate for at least five days. This means all of our own food, water, and lodging, and our equipment — antennas, rigs, power, and spare parts. We should coordinate with local authorities before, during, and after the disaster.

Communications Equipment

Although solid state equipment is more difficult for the average amateur to work on than is tube-type, it is more reliable and requires less power than does the tube-type.

Except in really isolated areas where "long haul" is needed from the disaster area, I would not recommend taking HF equipment into the area. In 1970, this recommendation would have been otherwise, as the nation was not so well covered with VHF capability.

Utilizing a battery, trickle charger, and a well-filtered power generator provides a well-filtered power source and steady power to the rig. The rig should be capable of working off a 12 volt battery. The new "sealed batteries" would provide an excellent source of power, and eliminate the danger of spilling battery acid.

Since disaster areas are rather localized, and we now have a large repeater network, two meters would be the equipment of choice for going to a disaster area. CB clubs all over the country are making preparations for providing communications in a disaster, but I believe in most areas two meters would give better coverage. Although 10 Watts output would probably be adequate, higher power would be better. Using a 40 Watt amplifier would not put too much additional drain on the batteries. At 10 Watts transmit power, and only a 50% duty cycle, a regular or heavy-duty car battery would probably last for several days.

Surrounding the disaster area there should be two meter stations and repeaters operating from commercial power to intercept and relay messages from the mobiles and portables in the disaster area.

Besides requiring less power, two meter equipment does not require as extensive an antenna system as does HF equipment. A Ringo-Ranger, or similar antenna, can provide up to 6 dB gain in a small antenna, and is easily mounted on a high point. Ideally, the shorter the coax run the better, but the loss with 100 feet of RG-8/U is only about 3 dB and this is more than compensated for by the antenna gain and elevation.

Why two meters instead of "220" or "450"? Mainly because there is much more two meter equipment available.

One must also consider that it would be easier to carry a spare VHF rig than it would be to carry necessary repair equipment.

Living Equipment, Supplies, and Transportation

Food, water, and lodging are scarce in disaster areas. If we do not want to be an additional drain on scarce resources, we should enter the disaster area as a self-contained unit. In some areas, officials will not let a unit enter the disaster area unless it is self-contained, or carries its own supplies.

A "high-centered," four-wheel drive, closed truck or van would probably be best for negotiating debris-strewn roads, and could go even where roads are impassable. From the standpoint of creature comfort, the self-contained motor home would be the first choice. Pickup campers and vans would be less desirable and camping trailers and travel trailers least desirable, due to problems with pulling, parking, and navigating.

Whatever your choice of transportation, there are certain basic supplies which you must carry — food, water, cooking utensils, stove, bedding, and first aid equipment.

It is always desirable to have hot food, but this means you also need cooking utensils and a stove. There are many types of camp stoves, using various types of fuel. Remember to carry the proper type of fuel for the stove which you use. Simple cooking utensils are best.

Food is a personal choice, but there are some basics to remember:

1. If you take canned food, be sure to take a can opener.
2. Highly seasoned or salty food requires more drinking water.
3. Certain foods, such as canned tomatoes, are "thirst quenchers" and reduce the amount of drinking water you need to carry.
4. Food should not require refrigeration for preservation, or you will have to worry about power or ice for refrigeration.
5. Don't carry food or water in glass containers; they might get broken.
6. Water for drinking should be not less than one-half gallon per person per day, and one gallon/person/day would be better. ■

Check-off List

—— Transceiver	—— Vehicle
—— Backup transceiver	—— Tow cable
—— Connecting cables	—— Jumper cables
—— Power cable	—— Car tools
—— Amplifier (if desired)	—— Spare tire
—— Power supply (batteries)	—— Jack
—— Power generator	—— Tire tools
—— Trickle charger	—— Spare gas
—— Antenna	—— Water
—— Coax	—— Canned food
—— Antenna mast	—— Bread
—— Mast guy lines	—— Jelly
—— Soldering iron	—— Camping stove
—— Solder	—— Bedding
—— Spare wire	—— Fuel for stove
—— Microphone and spare	—— Toilet articles

Ten-Tec Mods

-- improving a popular transceiver

The Ten-Tec Argonaut has proven itself to be a reliable high performance rig, ideal for portable/emergency as well as fixed station use. Even so, there are several modifications that can make the Argonaut more enjoyable to use.

Relocation of Drive and Mike Gain Controls

One of the major aggravations in operating the Argonaut is the placement of the important drive and mike gain controls on the back panel, while the relatively useless meter sensitivity control is on the front panel. If the drive control were easily reachable so that it could be turned down while the resonate control is peaked, there would be no need to desensitize the meter.

Fortunately, it is a relatively simple modification to move the drive and mike gain controls to the front panel by replacing the meter sensitivity pot with a dual concentric 25k pot. The procedure is as follows:

NOTE: These instructions assume that Ten-Tec has always used the same color coding in the wiring harness. Since this may not be the case, protect yourself by tracing the wiring to R14 and R16 and making notes of the colors and locations of each wire before disconnecting any of them.

View of front panel after modification, showing new dual drive and mike gain control. The main tuning knob with spinner is the one used on the Triton IV and is a direct replacement for the Argonaut knob. The Triton knob is available from Ten-Tec for $1, postpaid.

1. Remove the knobs, top and bottom covers, end pieces, and false front panel.
2. Remove all of the plug-in circuit boards, but before doing so, take a Sanford Sharpie or other fine point, non-watercolor, marks-on-anything marker and put an "F" on each board on the end closest to the front panel to avoid getting them in backwards during reinstallation.
3. Remove the meter sensitivity pot from the front subpanel. Tack solder a small 25k trimpot to the back of the meter switch where the wires from the sensitivity pot attach and discard the old wires.
4. Remove the nuts from the mike and speaker/phone jacks and swing them out of the way. Unsolder the wires from the drive and mike gain pots. Remove the pots from the back panel and fill the holes with 3/8" hole plugs (such as Radio Shack #21-920). Replace the mike and speaker/phone jacks.
5. The wires for the mike gain control all originate on the top of the chassis at the rear socket for the sideband generator/filter board. Pull them through to the top of the chassis and twist them together for identification.
6. The 2 grey and 1 white wire from the drive control should be fed to the top of the chassis through the same grommet that the mike gain wires were just pulled through.
7. The yellow wire that went to the drive pot connects to the bias pin on the socket for the rf power amp board. Remove the yellow wire and solder a new longer one to the bias pin. Feed the new yellow wire up through the space in front of the rf front end box and then route it along with the existing bundle of wires that runs along between the rf front end and VFO and then goes down behind the VFO and under the edge of the TX-RX mixer board.
8. Now that all of the wires for the two pots are in the correct general area, route them next to the chassis between the front sockets for the control board and the sideband generator/filter board and on over to where the pot will mount.
9. Dress the wires, trim them to length, and solder them onto the dual pot. (It is easier to wire the pot before it is mounted on the subpanel.) Refer to Fig. 1 or to the notes you made earlier for correct placement of the wires. Bend the resistor protruding from the side of the meter switch 90° out of the way and mount the dual pot on the subpanel. At this time, the 22k resistor (R15) associated with the drive control

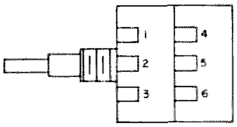

Fig. 1. Wiring the dual pot. Mike gain: 1. Yellow wire from sideband generator rear socket, pin 2; 2. Green wire from sideband generator rear socket, pin 3; 3. Black wire from ground lug near sideband generator rear socket. Drive: 4. 2 grey wires (1 from wiper of S3B, 1 from R13), 1 yellow wire from rf amp, pin 5; 5. White wire from S3B, contacts 2 and 4; 6. R15 to ground.

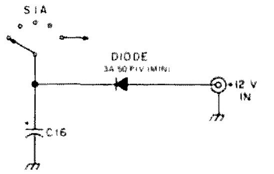
Fig. 2.



can be grounded to the pre-existing lug near the edge of the chassis. The dual pot that I used was a Centralab Fastach® II series snap-together unit consisting of an F1-25K and R1-25K, both taper C-1 (linear taper) and suitable snap-in shafts.

10. Double check your wiring. Replace the circuit boards, being careful to put them in the right way, and fire up the rig to check it out. Ensure that you have the pots wired so that clockwise is the increasing direction. Adjust the meter sensitivity trimpot to give a full scale reading at the rated power output.

11. Replace the covers and knobs. This completes the modification.

Reverse Polarity Protection for the Argonaut

With care, a reverse polarity accident need never happen. However, anyone can have a bad day now and then, and enough Argonaut owners have blown up their rigs with reverse polarity that Ten-Tec has a pre-packaged kit that includes replacements for everything that pops when the Argo is powered up backwards.

There are two approaches to reverse polarity protection. The quick and dirty way is to install a silicon rectifier diode between the center pin of the power jack and the junction of C44 (1000 uF 16 V) and the black wire. The diode should be conservatively rated (3 A 50 piv will do) and installed with the cathode

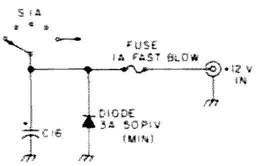


Fig. 3.

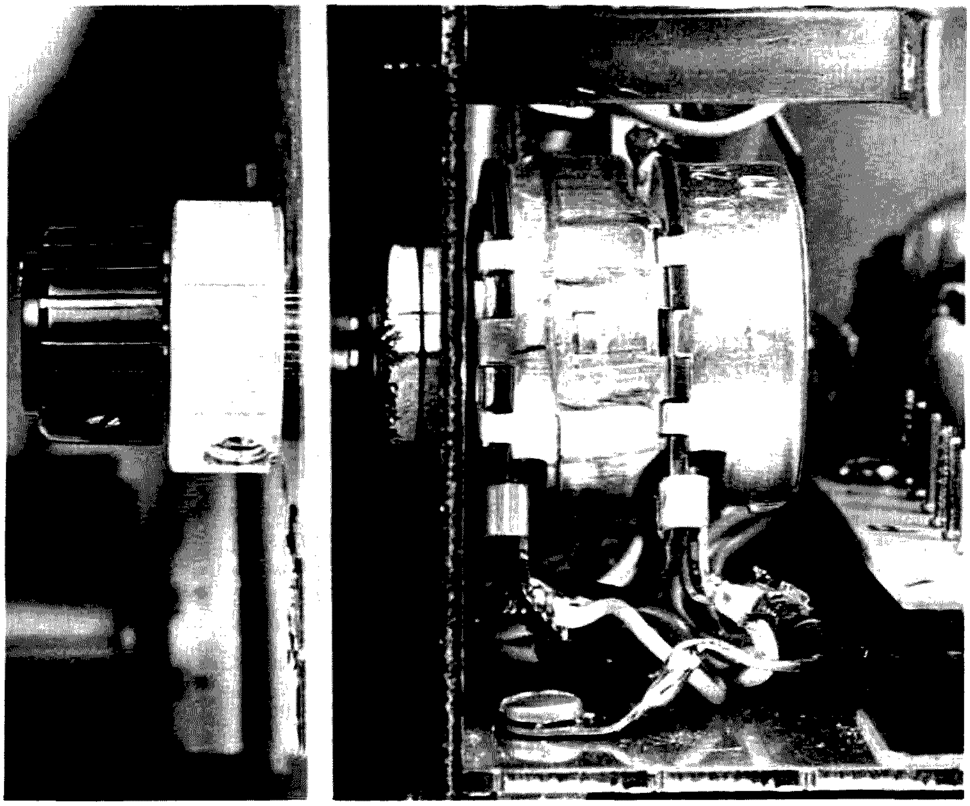
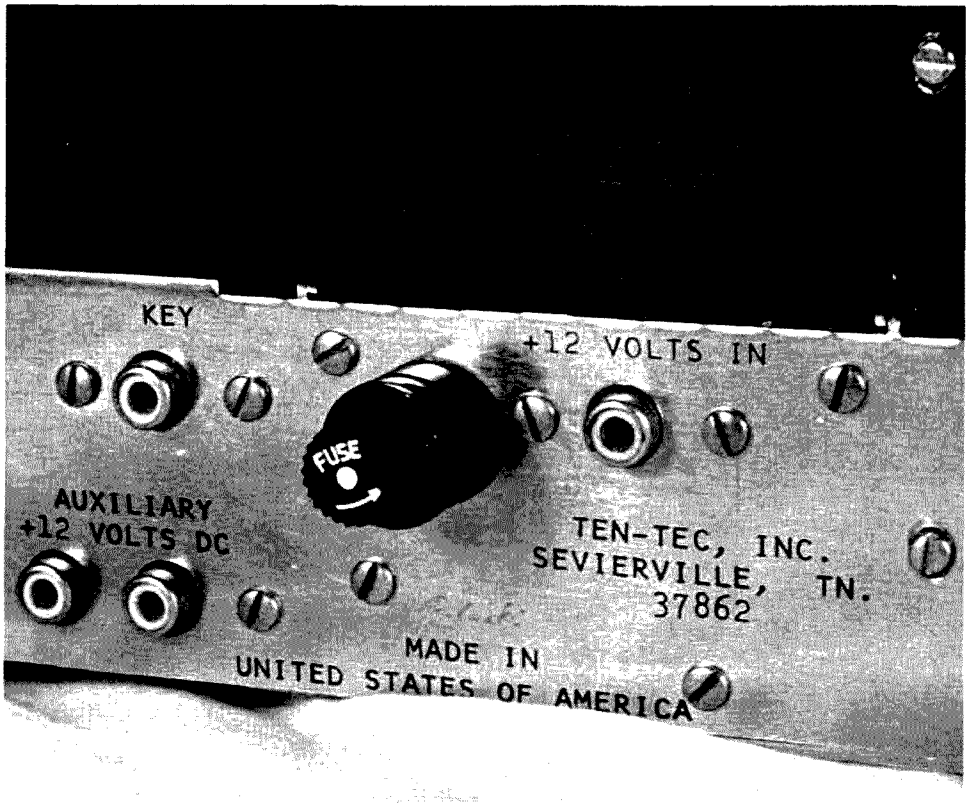
Detail showing the dual pot after installation. As can be seen, there is plenty of room for the larger pot. The solder lug at center bottom is factory installed and provides a perfect place to ground R15.

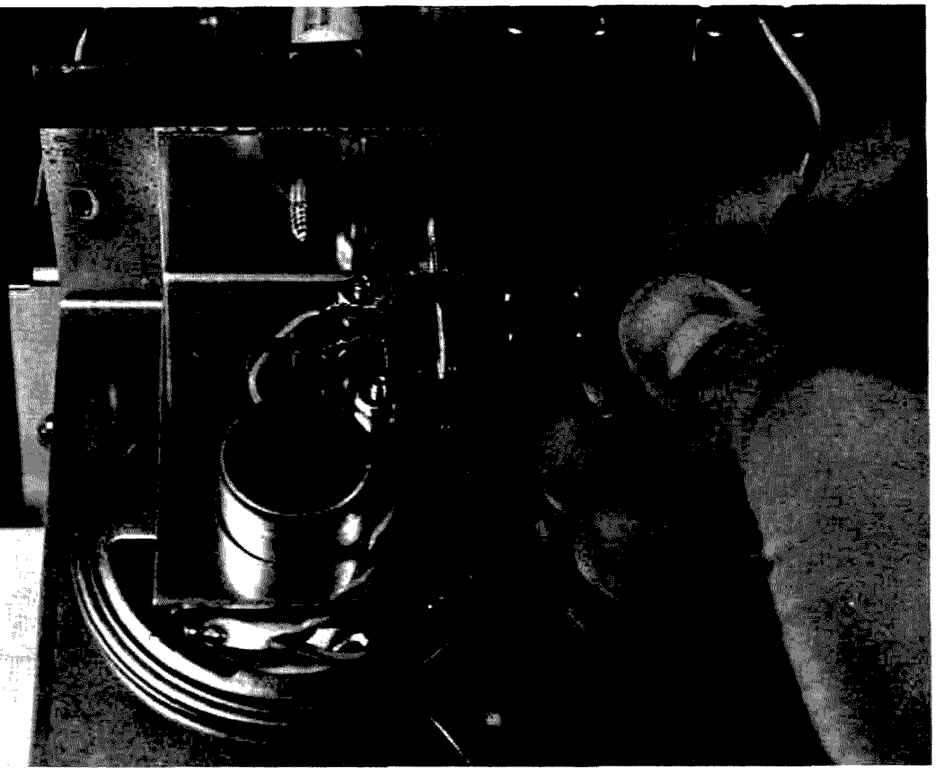


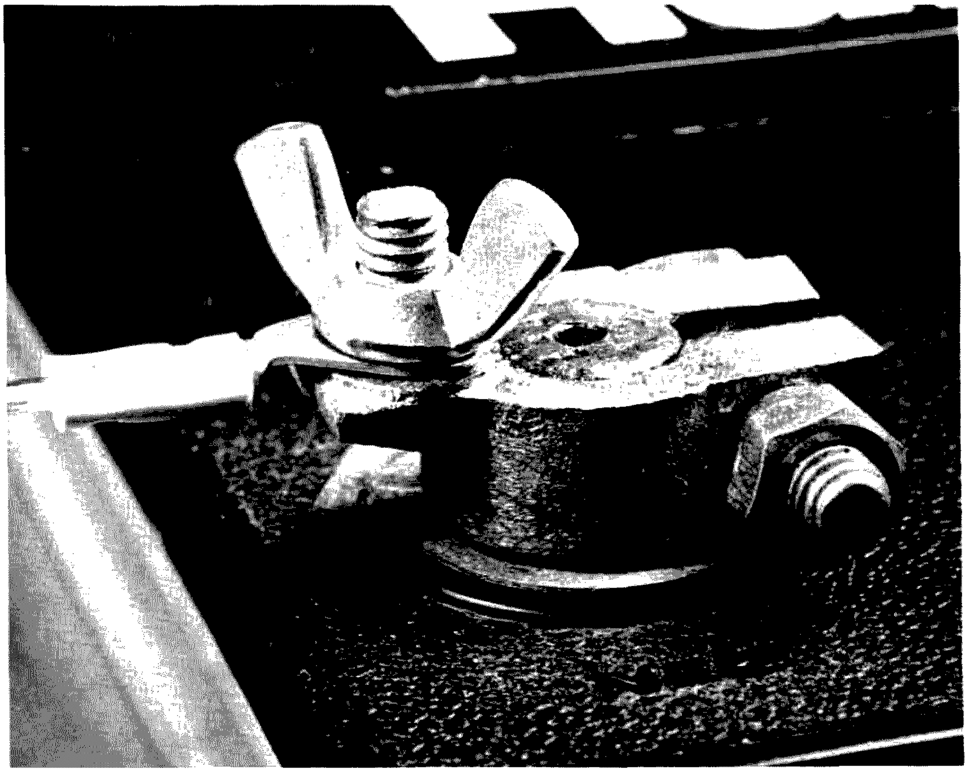


Rear panel view showing the location of the fuse post.

Aug 1977

Argonaut speaker as modified by homemade "L" bracket and 2 pin plug and socket set (Radio Shack #274-342), allowing cover to be detached for added convenience while working on rig.





A good low resistance connection to a car battery being used as a power supply is important, especially if you are powering a high current load device such as the Ten-Tec 405 Linear. A good way to get such a connection is with a battery post clamp with stud and wing nut terminal. Shown here is a Belden #7495 from a NAPA auto parts jobber. A similar item is available in the Sears catalog.

(banded) end toward the + side of C44 as shown in Fig. 2.

The drawback to this method is the approximately .7 V forward voltage drop exhibited by silicon diodes. When operating on weak batteries or other marginal power sources, this voltage drop could cause chirp or loss of VFO voltage regulation.

A better approach, offering more protection to the rig, is the method used in the Model 405 linear and other models in the Ten-Tec line. The power lead is fused and the fuse is followed by a reverse biased diode between + and ground, as shown in Fig. 3. Under conditions of correct polarity, the diode has no effect, but if polarity is reversed, the diode conducts heavily and blows the fuse.

It would be possible to install the diode inside the rig and make up an in-line fuse power cord, but a neater installation results from the use of a panel mount fuse holder. The space available for mounting is tight, so select a fuse holder that does not stick too far behind the panel (a Radio Shack #270-364 is satisfactory). The mounting location is slightly to the left of the power jack. It will be necessary to remove the top and bottom covers and the end piece closest to the power jack. Also, remove the screw that holds the receiver output trimmer strip and swing the strip up out of the way.

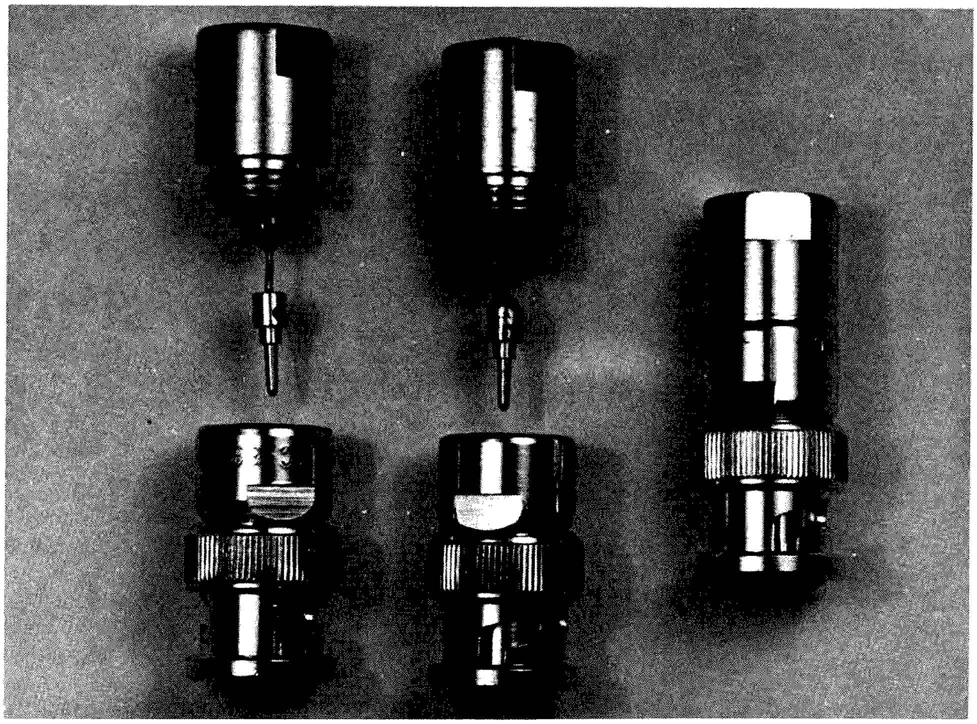
A ½" hole is needed for the fuse holder. Use of a Greenlee punch will minimize the amount of metal chips that fall inside the rig. You may have to snip the edge off the bakelite plate on the power jack to provide clearance for the fuse post.

Run a wire from the center pin of the power jack to the side connection on the fuse holder. Connect the + side of C44 and the black wire to the end connection on the fuse post, and place

the diode (at least 3 A 50 piv) in parallel with C44. The diode's cathode (banded) end goes to the + side of C44 and the other end goes to the grounded lug on the terminal strip where the - end of C44 grounds.

Shake out the drill chips and swing the trimmer strip back down and replace its screw. Check to make sure that none of the bare wires from the trimmer strip are shorted to each other or to anything else. Reinstall the covers.

Put a 1 A fast blow fuse in the holder. Under no circumstances should you use a slow blow fuse; to do so might result in the diode popping before the fuse does. Since the Argonaut does not actually draw a full 1 A of current, a 1 A fuse allows enough headroom to power small, low current accessories such as an audio filter and crystal calibrator from the rear panel auxiliary power jacks. ■



Converting Kings KC-89-66 BNC Video Termination into a QRP dummy load. Left is stock unit with 75 Ohm ¼ W film resistor. Middle shows installation of 51 Ohm 2 W carbon resistor. Because of the 2 W resistor's larger lead size, it is necessary to enlarge the holes in the center pin and case. Right is assembled unit. Because of the heat sink effect of the case, the dummy load can handle up to 5 W for short periods.

Fig. 1.

After reading the article by Robert Hatch WØTBL (*73*, Holiday, 1976, page 84) on the use of a computer to print log sheets, I decided that this sort of project was one which I might pursue. Unfortunately, I do not have access to a computer using FORTRAN, haven't the foggiest notion of how FORTRAN IV works, and was reluctant to impose on people who do. However, I have just finished a half-year course in BASIC programming on the PDP-8/e and decided that this was more my speed. This final fact placed the objective within my grasp.

The program, as shown in Fig. 1, is relatively straightforward for anyone familiar with BASIC. Almost all commands in the program have been abbreviated to their three letter abbreviations. The back slashes allow more than one command to be placed on a line. Inputs are provided for the number of QSOs per log page and number of pages desired, while string variables are input for the printing at the top of each log page of name, QTH, and callsign of the operator. These inputs allow for the user's own information and allow more than one person to use the same program.

I found the elimination of a column for "power" necessary due to the fact that standard teletype paper is only 8½ inches wide. Not enough room would remain for other information if I included a column for power. Since most people usually use the same power on any given mode, I included the power designation at the top of each page for CW and voice modes. If desired, the power to be used could be entered in the "other" column.

The judicious use of semicolons, commas, and quotation marks containing a number of spaces creates the proper spacing in the page heading. This technique also extends the last name of the operator and city name to a maximum of twelve characters (string length is a maximum of six characters with the PDP-8/e).

Obviously, the most efficient way to execute the program would be on a high speed line printer. However, it would be just as easy to set the computer to its task and have it print your log book on a TTY while you sleep (if you can stand the noise).

One final note: This program is by no means hard and fast. It is readily adaptable to the whims of the user. From this basic (no pun intended) format, one could print special contest logs to accommodate for special exchanges or print a log expressly for the traffic handler. The possibilities are almost infinite. ■

Troubleshooting A Micro

-- not as bad as it sounds!

Kenneth J. Hintz WB4KEO
222 Taylor Street
Fredericksburg VA 22401

While we are often bombarded with propaganda from Wayne Green and the manufacturers proclaiming the wonders of microprocessors and what they can do to automate our station or figure our income tax, we sometimes overlook the problems associated with trying to troubleshoot an ailing system. There is a good reason for this, based on the complexity of the functions that are being performed and the unavailability of test points within the chip. You must be somewhat of a detective to determine what is happening inside from the sparse information that is available to you externally. Fortunately, few of the problems are found within the microprocessor chip itself, but that possibility does exist. While there may be some exceptions to this, it has been my experience that, if the microprocessor will fetch and execute one instruction, it will probably fetch and execute all instructions.

Before starting the troubleshooting procedure, it is important to note whether or not the system is home brew or from a manufacturer. It is also significant whether it has been running and just died, or whether it has never run properly. While the troubleshooting that follows is applicable to all of these cases, there are certain problems that can be ruled out, depending on the previously mentioned conditions. For example, if it is a manufactured system that you are merely assembling, then it is unlikely that it is a wiring error on the cards that you have purchased. If it is your own handwired system, then the likelihood is that you've forgotten some interconnect or connected something up incorrectly.

If the system has been running but now fails, the problem can usually be traced to a faulty bus driver/receiver on the data or address bus. If the system is intermittent, look for temperature effects changing the response of memory, or look at that new interface or memory board that you just hung on the system. Much troubleshooting can be done by merely removing one memory or interface card at a time.

Before continuing, it may also be necessary to note those minimum pieces of test equipment that are required for troubleshooting a system. While some rudimentary checks can be made with a VOM, the system must be looked at dynamically with at least a 10 MHz bandwidth scope. This scope should have at least external triggering and preferably dual trace. Yes, you can look at the buses with slower scopes and see the transitions, but we are looking for problems that may be associated with 50 ns pulses of noise riding around on signal lines, and you will never see them without the prerequisite bandwidth. The microprocessor should also be set up with a hardware restart switch connected directly to the chip itself (or through a peripheral chip designed to do this), so that it can be repeatedly restarted. The reason for this will be evident in later discussion.

There is also one class of problem that is not discussed here, and that is the passing of misinformation by the manufacturer. Occasionally, errors are made in the manuals, or changes are made in the chips that cause them to not function as advertised. This, of course, pertains mostly to the

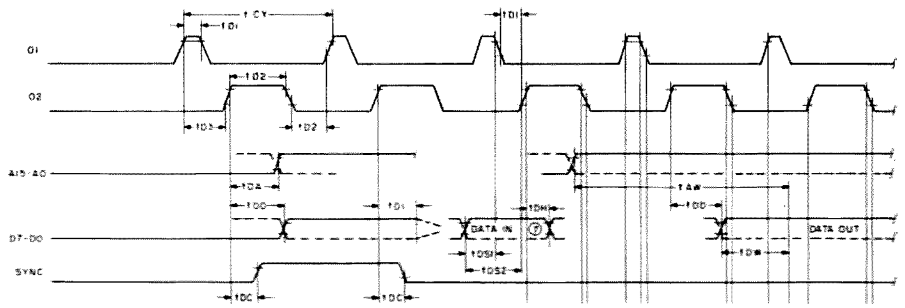

Fig. 1. Timing diagram for an 8080A microprocessor. Intel specifies $t\phi 1$ as 60 ns minimum, tCY as 480 ns to 2 microseconds, $t\phi 2$ as 220 ns minimum, tD3 as 130 ns minimum, and tD2 as 70 ns minimum.

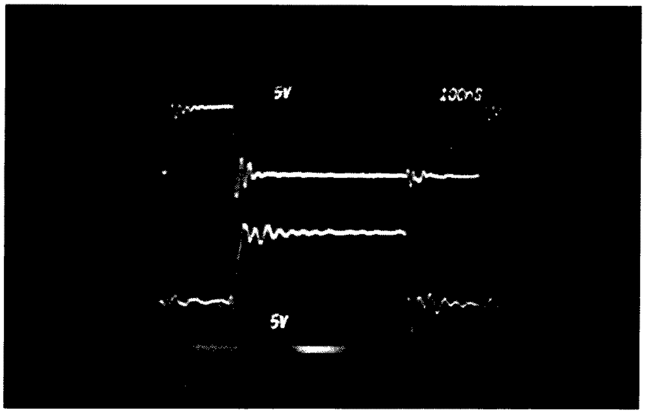

Fig. 2. Scope photograph of an 8080A's two phase clock. The top trace is phase one and the bottom trace is phase two. Note that the clocks are not TTL signals and that they meet the timing requirements as outlined in Fig. 1.

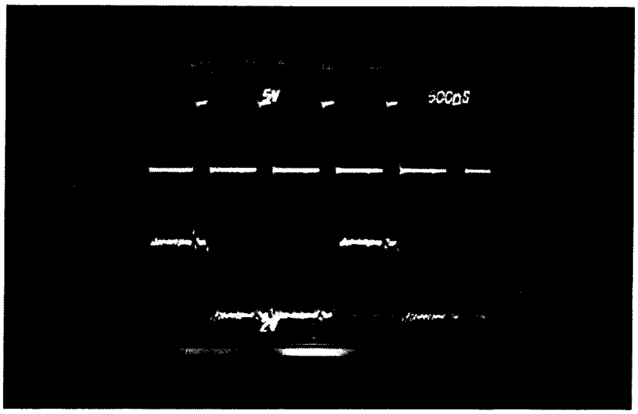

Fig. 3. Timing relationship between phase one and synch for an 8080A running at a crystal frequency of 9.5 MHz.

home brew systems. Don't be afraid to call up the local field applications engineer for the company that made the chip and explain your problem. They are, in general, knowledgeable about their product, and may have actually encountered the problem before. If it is a long distance phone call, call them before they are in the office and leave a message with their answering service to have them call you. It may save you quite a phone bill.

Enough of the boilerplate. As with all electronic problems, beware of the obvious. That is, whether it is a microprocessor that just plain refuses to work, or one that intermittently fails to execute its program properly, start with some of the basics which are often taken for granted.

Power Supply Voltages

The tolerance on power supplies is ±5%, or 4.75 to 5.25 volts for the 5 volt supply and 11.4 to 12.6 volts for the 12 volt supply. And that is a clean five/twelve volts and a clean ground line. While you wouldn't expect it, most of the digital noise that is found is on the ground line. It should be the first suspect for intermittent faulty operation, assuming that it has never yet worked completely right. Adequate current reserve in the power supply and sufficient bypass capacitors are required for proper operation. As ballpark numbers, 10 microfarads per twenty chips and 0.1 microfarad (for high frequency bypassing that the electrolytic can't handle) near each chip that drives signals off of the card or over long distances (e.g., bus drivers) should be sufficient.

Another point to remember about checking power supply voltages is to check them at least on the card, if not near the chips themselves, for two reasons. The first is that if a power supply with no voltage sensing is used, the voltage at the power supply may be set to five volts. But, because of losses due to the high currents and small gauge supply wires, the voltage at the chips may, in fact, be below the 4.75 volts minimum. Secondly, if remote sensing is used, the sense line may be open, or the regulating circuitry not operating properly.

Clocks

To operate properly, microprocessors must be supplied with clock signals, since all of the internal functions are performed synchronously. Not only must these signals be present and of the proper duration, but they also must be free from glitches and in the proper timing relationship. Fig. 1 shows a timing diagram for an 8080 showing a two-phase clock. Note that the duration of phase one must be a minimum of 60 ns, the delay between the rise of phase one and the rise of phase two a minimum of 130 ns, and the delay between the fall of phase two and the rise of the next phase one 70 ns minimum. An actual photograph of an 8080A's clock signals is shown in Fig. 2. While the clock was being run at 9.5 MHz, rather than the maximum of 18 MHz, it can be seen that the minimum times are met. A measurement like this can not only be made on a dual trace, 10 MHz scope triggered only by the phase one input, but can also be done on a single trace unit with external trigger. First, phase one is displayed and checked in terms of glitches and minimum pulse width and maximum pulse interval. The triggering is now set up for this signal, and it is moved to the external trigger input (with the scope triggered from this source). Phase two is now connected to the vertical input and displayed, relative to phase one. It may make it easier if phase one is written in on the face of the display with a grease pen.

Instruction Execution

We are now assuming that the microprocessor is hard down and won't do anything. First, disconnect all cards/interfaces/memory, except for Read Only Memory (ROM); then program a ROM with a jump-to-self instruction. In the case of an 8080, the instruction would be as shown in Table 1. It is, quite literally, Jump (C3H) to the address (0000H) which follows.

While this can be done with other instructions on different machines (such as those with program counter relative addressing), the principle is the same: Try to get the machine to do the minimal amount it can do and still keep fetching and executing a predictable instruction. Now, how do you know if it is running? Look at the synch signal out of the microprocessor. (In the case of the 8080, there is one synch per instruction execution.)

The first check, in this case, is to look at the synch (see Fig. 3) while the reset (a hard reset to the microprocessor through a switch closure) is activated. This reset should set the internal program counter to the starting address where the first instruction will be found (0000H in the case of the 8080), and the microprocessor will run for one, two, or a number of instructions and then halt. Each of these has a significance. One instruction execution (or synch pulse) means that the microprocessor recognized the reset and has gone out to fetch the first instruction from its starting address. If you don't see at least one synch, it is probably a microprocessor chip problem. If a second synch pulse is found, it means

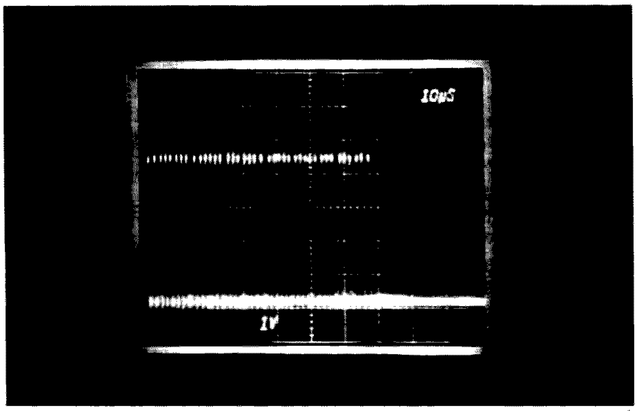

Fig. 4. Synch pulses showing the effect of a microprocessor fetching several instructions and then dying. This can be one of the hardest problems to diagnose. It is usually attributable to slow memories.

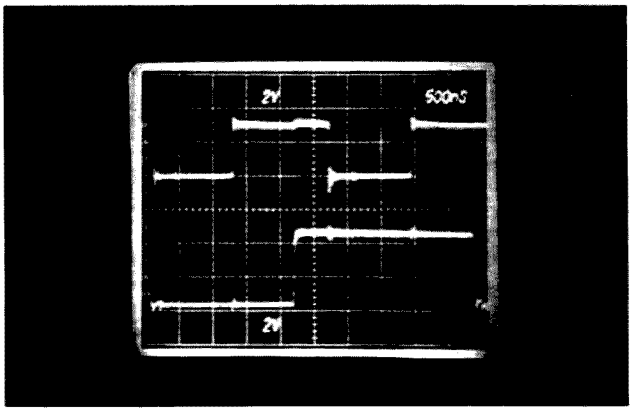

Fig. 5. The top trace is read memory bar (low is true) pulse. Address information should be stable during this time. The lower trace is an address line showing a solid zero during RM pulse one and a one during RM pulse two.

that the microprocessor has output an address, and something has come back. What you don't know for sure is what actually was read from memory. But, you do know that it is going out and fetching. If our dummy instruction is being fetched a number of times (this could be into the hundreds – see Fig. 4), and then dies, this can probably attributed to slow memories. To test for this, slow down the system clock. "How?" you say. "It's crystal controlled." First of all, there is nothing that says that it has to be crystal controlled and, second, any ham should have miscellaneous crystals around that are less than the value (preferably ½) of the crystal frequency currently being used in the system. Insert the crystal, verify that the clock is running, and see if the microprocessor still dies. If it does, we have to look further.

Address	Contents
0000Hex	0C3Hex
1H	00H
2H	00H

Table 1.

Address Bus

Whether we are at the one, two, or three or more synch pulse stage, it is advisable to check the address bus for proper operation. We are, of course, assuming that the ROM with the jump-to-self instruction is still in the system at the starting address of the microprocessor. One method of checking for proper operation of the address bus would be to synch to the read memory pulse, as this must occur during the time that the address bus is stable. In any event, we should alternately push the restart button and look at each of the address lines to see that the desired starting address is being presented to the ROMs during the time of the read memory pulse. Fig. 5 shows a read memory bar (low is true) on the top trace and an address line on the lower trace showing a good zero. No read memory pulse? Probably a bad CPU chip. What you may find is that the leading edge of one of the address lines, either rising or falling, occurs during the read memory pulse. Since this pulse says that the addresses are stable, something is awry. Since there should be nothing on the address bus other than the microprocessor itself and the ROM, the problem is probably not excessive capacitive loading of the bus.

More probably, it's a faulty bus driver/receiver chip if one is used, or a short to Vcc or ground. A lack of noise on an address line is a good indicator of a short to ground. Usually, one address is found to be at fault, and this quickly isolates the offending chip or shorted line. Should all of the address lines be pulling to the required one or zero during the read memory pulse time, then we must look elsewhere for the problem.

Data Bus

The troubleshooting of the data bus can be somewhat more tedious than the previous problems, and so it is left to last. Part of the problem is due to the fact that it is a bidirectional bus and can be transmitting data either to or from the microprocessor. Since the bus is bidirectional, some means must be maintained to keep track of whose data is on the bus at any given time. In a simple system this is easy, because the microprocessor is controlling the bus, and the interfaced hardware has only specific times during which it can put data on the bus.

To digress a moment, although the reader may be familiar with TTL (transistor-transistor logic), to understand the concept of a bidirectional bus, tri-state logic must be brought in (not at the expense of open collector buses, but it is easier to see what is happening on them). Not that understanding them is difficult, for when it is enabled, a tri-state output looks like any other TTL signal. When the chip is not enabled, the output assumes a high impedance state. Referring to Fig. 6, it can be seen that the normal TTL output is a totem pole arrangement of two transistors, one of which is nor-

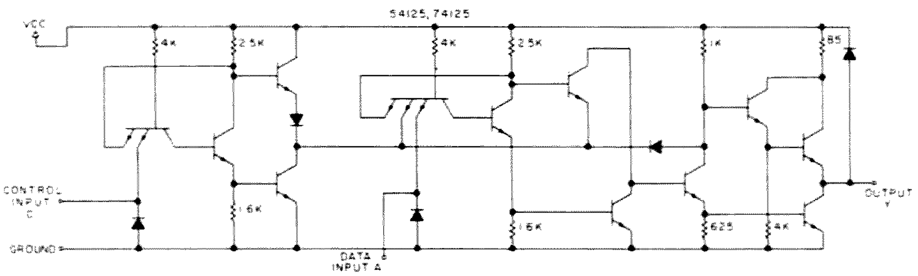

Fig. 6. Schematic diagram of a Signetics 74125 quad bus buffer gate with tri-state output. During the tri-state condition, both output transistors are in the high impedance state.

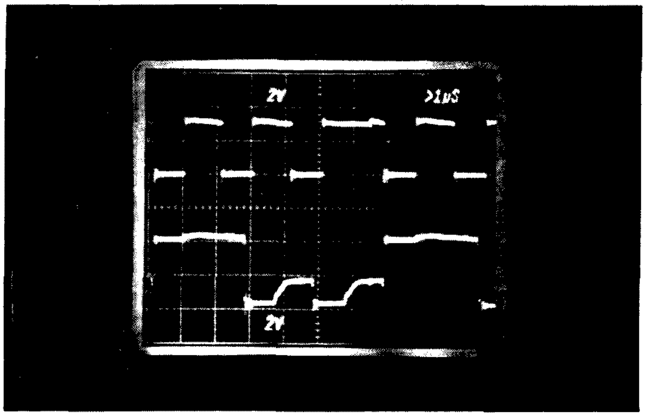

Fig. 7. The top trace again shows the read memory bar ($\overline{RM}$) pulse to allow proper interpretation of the data bus information on trace two. Note that during the first two $\overline{RM}$ pulses the data bus line shows a good one, but during the third $\overline{RM}$ pulse the line shows neither a good one nor a good zero, indicating that the microprocessor was addressing nonexistent memory or the memory at that location was malfunctioning and putting nothing on the bus.

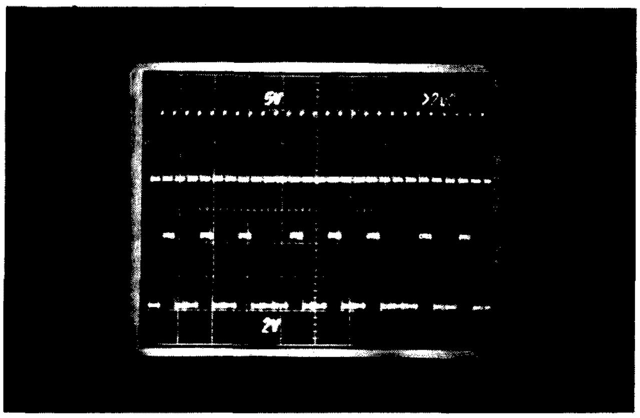

Fig. 8. The top trace is phase one of the clock and the bottom, the synch pulse of a normally operating system. Time between synch pulses will vary, depending on the instruction being executed.

mally on while the other is off. In fact, what accounts for the large noise spikes in TTL circuitry is that for nanosecond periods of time, both transistors may be on, causing a direct short to ground from Vcc. Looking at it binarily, there is only one other possible state for the two transistors, and that is with both of them off. In this case, looking back into the output of the tri-state device, we see a high impedance to both ground and Vcc and, hence, a very low loading of the data bus.

In the simple case of our jump-to-self instruction, the microprocessor releases control of the data bus during the read memory pulse (and slightly before and after). It is this pulse (read memory) that is logically combined with the decoded address on the address bus to provide a chip enable signal to the ROM so that its tri-state output is enabled and the next instruction put onto the data bus. So the first thing we must do is to look at the pin on the ROM for the chip enable to see if it is, in fact, being enabled. A lack of a chip enable signal says that the problem can now be localized to the chip-select decoding circuitry. If it is present, we continue by looking at the data bus, bit by bit, in synch with the read memory pulse. (At least one should be generated each time the microprocessor is reset.) While it is typically the case that all of the data lines are pulled high (through externally supplied pull-up resistors) so that they go to a known state while they are not being enabled, this is not required, and you may see a data bus without them that looks like Fig. 7. Note that the information on the bus is only valid during the read memory pulse time, so both signals must be displayed, or at least synched. Check, as with the address lines, to see that the data is fully a one or a zero during the time that the read memory pulse is there. Fig. 7 also shows the effect of nothing being on the bus during a read memory pulse. [During the third read memory bar (low is true) pulse, the data bus is neither high nor low.]

If All Else Fails

About the only thing left that can give you fits is an unpredictable interrupt being forced onto the microprocessor through a faulty interrupt controller, an interrupt line that is going low, or one that is not tied high through a resistor (allowing noise to pull it low). Check all interrupt lines for noise. If the chips are mounted in sockets, remove them, use solvent, and reinsert them to allow for a possible faulty interconnect. The same goes for the insertion of the board into its socket. This can be a great source of intermittent aggravation, when it dies every twenty minutes and then starts up with no problems. Another somewhat elusive problem is changing chip parameters with an increase in temperature, especially if the device is being run at close to its rated speed.

So, let's assume that life is not being cruel to you, and the first time that you put the jump-to-self instruction in, the synch pulses look like Fig. 8, and everything else appears to be operating normally. Now is the time to put your rudimentary monitor program ROM back into memory and see if the monitor functions (e.g., reads memory, changes registers, etc.). If not, recheck with a scope all of the address lines, data lines and interrupt lines. After a while, you can tell when a line looks correct, even without doing all of the synching, etc. You may want to still check them while you synch with the read memory pulse to check for a slowing of the response of the address and data buses due to capacitive loading increases when additional ROMs are added. If you don't have a small monitor program, put in the minimum amount of software and interface that you need and see if it will work. Slowly add interfaces and memory until the problem occurs. If you are lucky, you should be able to look at each of the address and data lines and see the one that is degraded by the malfunctioning board. If those show nothing, look on the most recently inserted interface/memory board to ascertain if signals are getting through to it. Perhaps it is being enabled all of the time, or conversely, never, due to faulty logic on the board. Hopefully, the insertion of boards one at a time will point out the defective board, and a look at all of the lines going to that board will give you a starting place for troubleshooting.

Read the Manual

Since you probably plugged the thing in before you really understood it, and it (miraculously) worked, or it worked after you only read half of the book, read the other half. Experience has shown that the microprocessor is probably not running because you forgot to read footnote number three at the bottom of page sixty-seven, which says that pin five of board six must be grounded for proper operation. ■

Super DVM

-- uses the MC14433 and LCD

Tim Ahrens WA5VQK
2200 Sorret Tree Ct.
Austin TX 78744

I have, for a long time, wanted to replace my old reliable Simpson 260 due to its rapidly deteriorating condition. My first thought, thanks to some free samples from various companies, was to go the route of a voltage to frequency converter. Well, by the time I decided to start development on it, I had been transferred to Austin, Texas, where I was introduced to the new Motorola chip, the MC14433 analog to digital converter (DVM) chip. My first attempt was an LED version, with limited functions (volts only). The current demand on the batteries was not too bad – about 60 mA. With nicads, this could be taken quite easily. But, wanting to expand my horizons and to know what makes those funny liquid crystal displays work, I decided that the next voltmeter would contain only devices which wouldn't suck up all the juice out of the batteries. Before we get into the actual circuit construction, let's start from the top with design theory.

The Display

The operation of a field effect liquid crystal display depends on changing the optical properties of a liquid crystal by applying an electric field. The best short description of a liquid crystal is that it is an ordered fluid. Crystals of this type (liquid) which are used in displays belong to a class called *nematic;* fluids of this type consist of cigar-shaped organic molecules with the long axis of each molecule pointing in the same direction. There are three main types of chemicals which are used in displays. These are Schiff-bases, esters, and biphenyls. At the present time, the Schiff-bases are the best choice for displays, taking into consideration switching times, reasonable threshold voltages, lifetimes, good temperature ranges and expense.

The Motorola MLC 400* is constructed from two pieces of glass coated with transparent indium oxide conductors. These conductors are shaped to form the segments of a numeric display. The glass surfaces are also specially treated to align the liquid crystal molecules in a particular direction. Alignment is parallel to the plane of the glass, with the alignment direction of the top rotated 90° relative to the alignment of the bottom plate. This causes the liquid crystal molecules in the cell to assume a twisted orientation, when viewed from top to bottom. The plane of polarization of plane-polarized light will follow this twist and emerge from the cell rotated ninety degrees. Thus, if the cell is placed between crossed polarizers, the polarizers will transmit light. Where an electric field is applied, the liquid crystal will align parallel to the field, twist will be destroyed, and that portion of the cell will

*From Motorola Communications Engineering Bulletin #42, ***Motorola Field Effect Liquid Crystal Displays – A light look.***

appear dark between crossed polarizers. Now I bet you didn't think all of that could fit inside a watch case, did you?

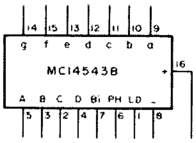
The MC14433

The MC14433 is a high performance, low power, 3½ digit A/D converter combining both linear CMOS and digital CMOS circuits on a single monolithic IC. The chip is designed to minimize use of external components. With two external resistors and two external capacitors, the system forms a dual slope A/D converter with automatic zero correction and automatic polarity. The MC14433 is ratio-metric, and, by itself, may be used over a full scale range from 199.9 millivolts to 1.999 volts. Systems using the MC14433 may operate over a wide range of power supply voltages for ease of use with batteries. In addition to DVM/DPM applications, the MC14433 finds use in digital thermometers, digital scales, remote A/D, A/D control systems, and MPU systems and has an input impedance of greater than 1000 megohms!

This A/D system performs a ratio-metric A/D conversion; that is, the unknown input voltage, Vx, is measured as a ratio of the reference voltage, Vref. Therefore, a full scale voltage of 1.999 V requires a reference voltage of 2.000 V, while a full scale voltage of 199.9 mV requires a reference voltage of 200 mV. Both the Vx and Vref are high impedance inputs.

OK, now that we have gone through the dry stuff, let's dig into the actual meat of the article.

The circuit in Fig. 3 performs parameter-to-voltage conversions, scaling and function switching. The ac/dc DPST switch changes the input path and the signal is then fed into the MC14433. A 10 megohm voltage divider consisting of three precision resistors provides 2, 20, and 200 volt ranges. Three precision shunt resistors are connected directly from the input to ground, providing 1 A, 200 mA, and 20 mA scales.



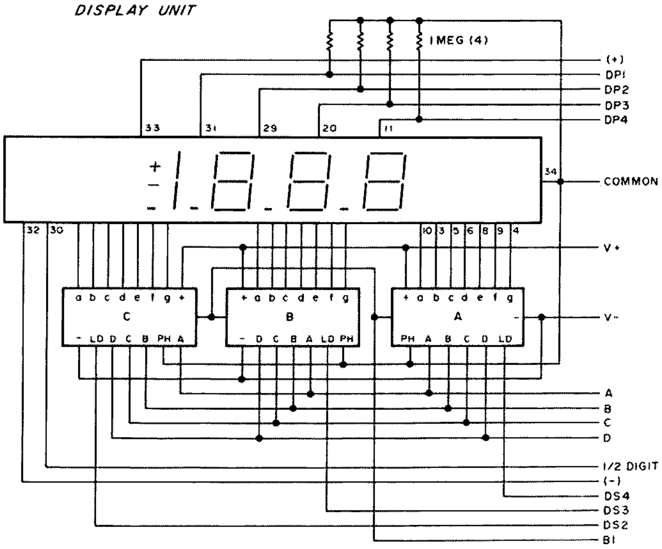


Fig. 1.

The resistance scales are established with calibrated current sources using the MC78L05 and MC79L05 voltage regulators. A stable 5 volts above the minus supply is produced by the 78L05 positive regulator. The current sources are simple base emitter biased transistors. A 2N930 with a guaranteed beta at 1 microamp is used for the 2 megohm scale, and an MPS6513 is used as a .1 mA source for the 20k Ohm scale. Each is adjusted by a single ten-turn pot. The 200 Ohm scale current source uses a 79L05 negative regulator. Its input is connected to the negative supply and a scaling resistor is placed between the common and output pins. When not in use, this circuit draws only a few microamps of bias current, even though it sinks 10 mA when measuring a connected load. All current sources are biased from the minus supply to increase battery life; thus, all resistance scales produce a negative sign on the display.

When I first was breadboarding the circuit, I took the minus supply for the input circuitry from the common -6.2 V bus. The only problem with this is that the 78 and 79L05 regulators require about 2 to 3 volts over the output voltage to work properly. Thus, the regulators will require at least 7 to 8 volts on the input to give 5 volts on the output. No wonder I was getting funny readings! For this reason, I recommend the use of 9 volt batteries. Note that absolute maximum voltages on the MC14433 are + and - 8 V, so be sure to drop that portion of it somehow.

The real substance of the project is shown in Figs. 1 and 2. Three MC14543N LCD latch/decoder drivers are used to demultiplex, decode the three digits and drive the LCD. The half digit and polarity are demultiplexed with the MC14013B dual D flip-flop. Since the LCD requires an ac signal across it, the low frequency square wave drive for the LCD is derived from the MC14024 binary counter, which divides

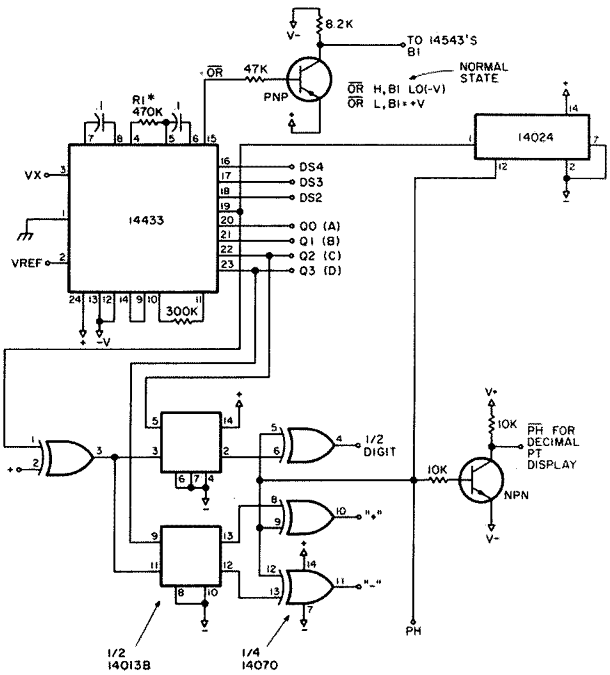

Fig. 2. For V full scale = 199.9 mV, set Vref = 200 mV and R1 to 27k Ω. For V full scale = 1.999 V, set Vref = 2 V and R1 to 470k Ω.

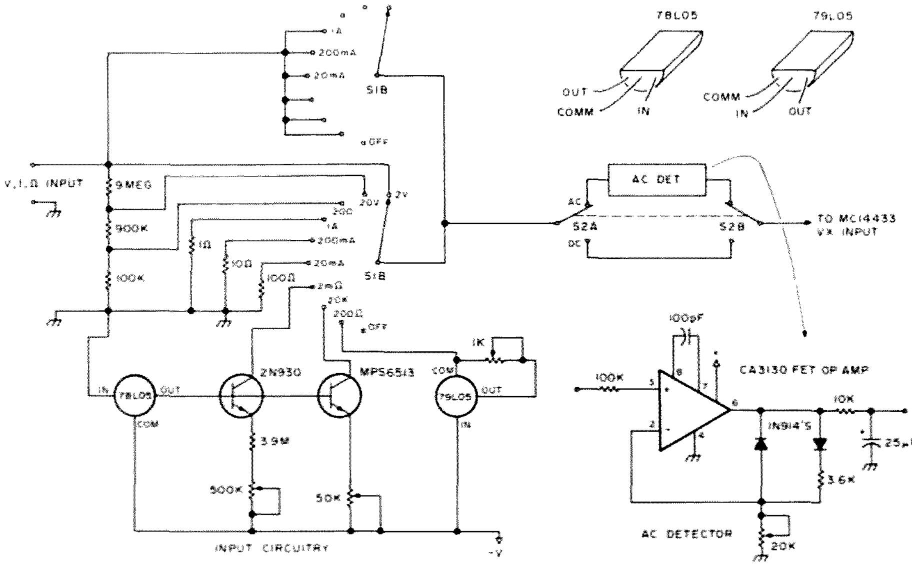

Fig. 3.

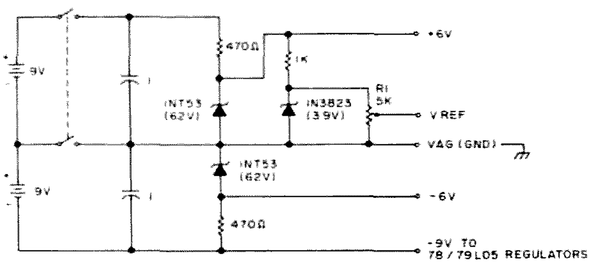

Fig. 4. Power distribution. Set R1 for an output voltage of 2 V. It must be accurate and with load connected. Any zener diode of equivalent value may be used.

the digit select output from the A/D. Although this is a convenient way to obtain the required square wave, it is not necessary to take it from here. The frequency should be about 4 kHz, as this will provide for the best contrast on the display unit. This low frequency square wave is connected to the backplane of the LCD and to the individual segments through the combination of the output circuitry of the 543B and the exclusive OR gates at the outputs of the 013B. All of the decimal points are tied to PH through a 1 megohm resistor, and, to display a particular DP, it is switched to $\overline{PH}$.

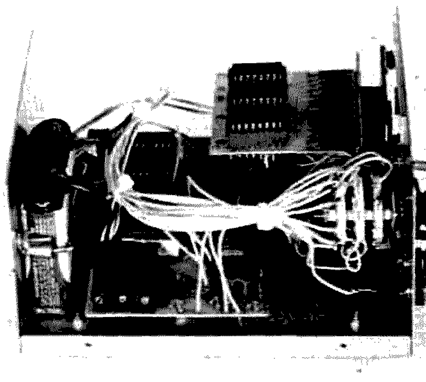
The overrange pin (15) goes low when Vx exceeds Vref. It is normally high. The 543Bs require a ground on pins 7 (blanking) to display. In our case, the ground is actually the most negative supply (to get the maximum amount of voltage swing on the output). This normally high $\overline{OR}$ pin on the 433 is tied to a PNP transistor, which is tied between -V and +V. In its normal state, the transistor is not conducting, thus allowing the -V to be on the collector. When the input goes low, indicating an overrange condition, the transistor conducts and places a high (+) on the blanking input of the 543s, thus blanking them. Note that the first digit has no provision for blanking.

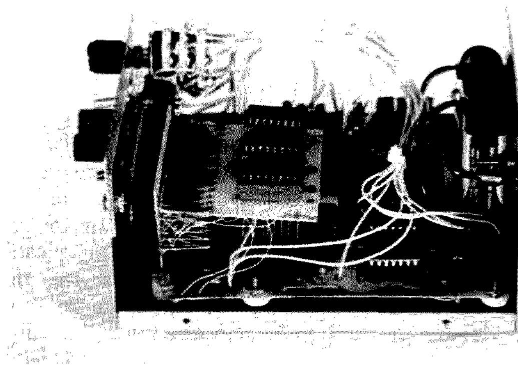
In my version, I wire-wrapped the LCD socket and the 543Bs. I did this for a couple of reasons. The first reason is because the pins of the socket of the LCD are very close together, and I didn't want to hassle with the artwork. The second reason is that my wife gave me a hobbywrap tool for Christmas, and I wanted to try it out. It would, of course, have been permissible to etch the whole board, but I elected to go with the wire-wrap method. I later found out that Teledyne Kinetics, the maker of the LCD socket, also makes a socket that would allow construction on a single board.

Calibration

The first thing to do in the way of calibration is to set the reference voltage. Note on the schematic that it can be set up for 2 volts or 200 mV full scale. I recommend that it be set for 2 volts due to possible noise problems, but, even with the 2 volt scale, it can be read to .001 volt. Be sure to be accurate with this reference voltage, as the accuracy of the entire instrument depends upon it. A short word about the quality of components used in the frequency determining resistors and capacitors, especially in the capacitors. These .1 uF caps should be of the high quality polyester or mylar. Using cheap caps here can lead to inaccurate readings.

If you used precision resistors for the voltage divider network, the next step is to calibrate the Ohms scales





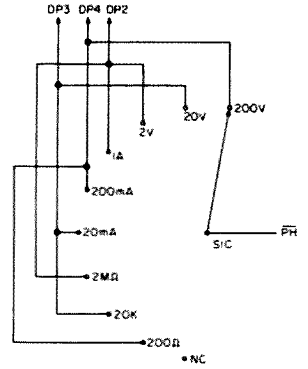


Fig. 5. Decimal point switching. To energize DP, tie line to $\overline{PH}$.

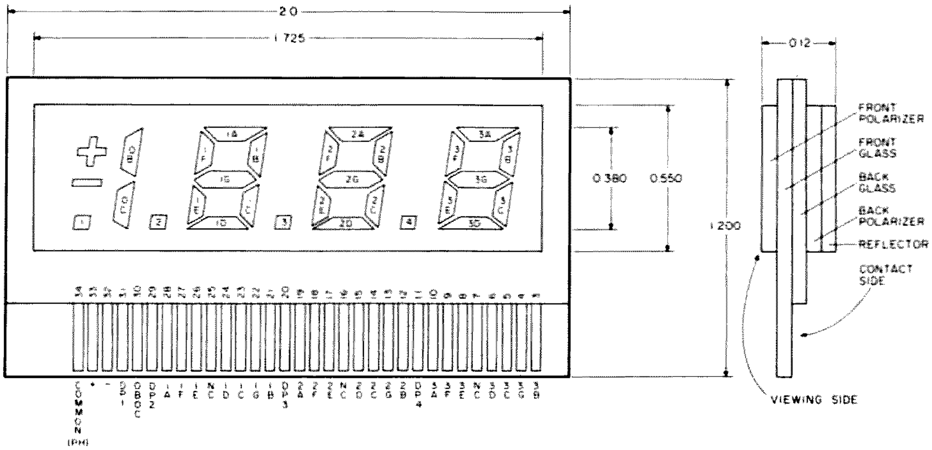

Fig. 6. Diagram of MLC400 liquid crystal display. Use connector Teledyne Kinetics S202U.

against known resistance values. Just tweak the control until the correct value is displayed. If you used pots in place of the precision resistors (in the interest of saving money), you must set these up. The way to do this is to get a calibrated voltage source. Set the voltmeter to the 200 volt range, and adjust the 100k pot for a correct reading on the meter with about 90 to 120 volts applied to the input. Watch out, as the 433 doesn't really like all that voltage, especially if it is applied directly to the 2 V scale. It might blank out forever! After you have calibrated the 200 volt scale, don't touch that pot again. Apply about 16 volts to the input, and adjust the 900k pot for a correct reading. Next, do the same thing for the 2 volt scale, using the appropriate voltages. After this, you will probably have to touch each of the pots up, as each will interact with the other. With a little time, you can save yourself a little money, and probably have a more accurate meter than if you were to buy precision resistors!

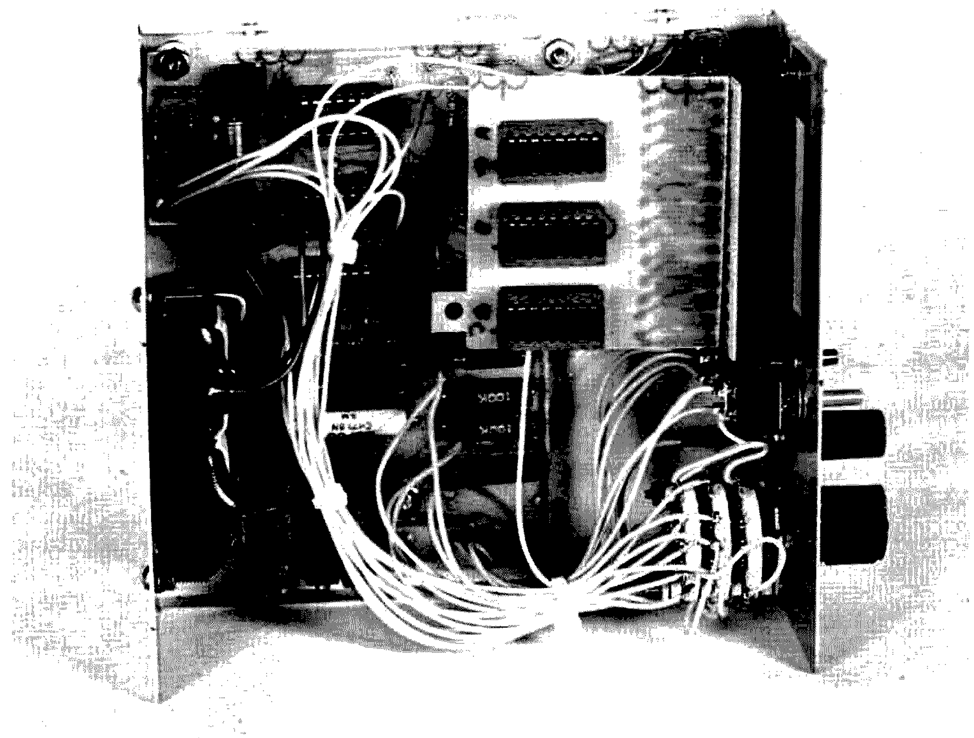
There are a few things which you should be on guard for, and those are in the area of the ac detector circuit. Since this is essentially an amplifier/detector circuit, anything that is placed on the input will show up as a dc potential on the output. This little lesson was painfully shown to me, as the ac detector circuit took more time to refine than did the rest of the DVOM. On the switch assembly, I ran the PH and $\overline{PH}$ lines with unshielded wire. This was a real no-no, as the input is a very high impedance, and therefore doesn't take very much to drive it. So, a little shielding and careful placement took care of it.

To calibrate the ac scale, the easiest way is to set up the voltmeter to the 200 volt scale and the measure the line voltage of your house. If it does not read correctly, turn the pot until it does.

Another little hint — be sure not to hook up the analog ground to chassis ground as if you are measuring current in a high voltage circuit. This will place a high potential on the bare metal chassis. In my DVOM, the chassis is floating and not connected to anything. At the present time, I do not know where the display unit can be purchased, but a rough price estimate for it would be about $14.00. The chip is available from Tri-Tek for $18.95.

PC boards for a basic 2 V DVM using LEDs can be purchased from Dactron, Inc. 12609 Blackfoot Trail, Round Rock TX 78664.

In addition to this basic 3½ digit 2 volt LED DVM, this company is coming out with the following items: plug-in board with full function, autoranging capabilities, LCD version, and a digital thermometer. ■



Build A kW Linear

-- a 4-1000 provides the punch

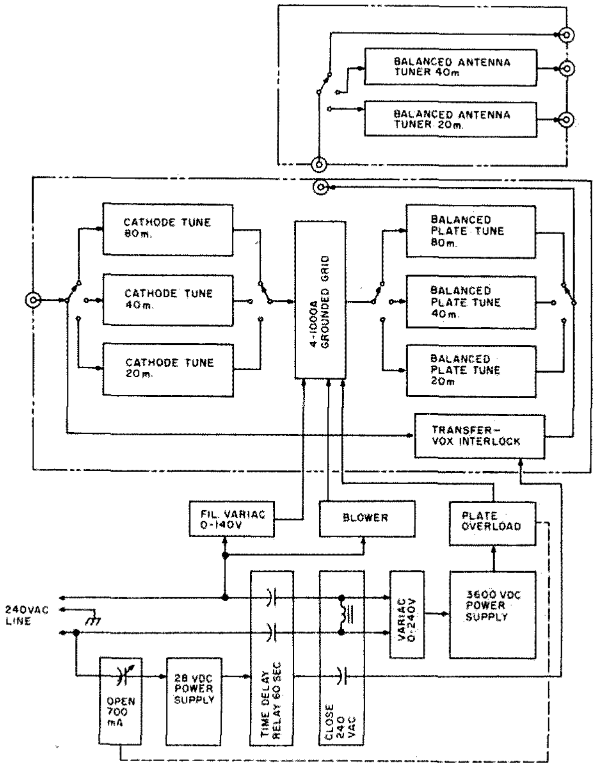


Fig. 1. Amplifier system.

Torrance CA 90505

The ultimate station, from the viewpoint of most of us, would be one located on a hill remote from noise sources, having separate, large, highly elevated antennas for each band. The ham shack would contain a separate kilowatt transmitter for each band, pretuned and correctly matched to its separate antenna by means of an rf bridge, and ready for instant use. Unfortunately, not many of us can afford such an arrangement.

This article describes a compromise available to all who have the desire and perseverance to learn and build. This is a kilowatt linear amplifier of highly efficient and conservative design employing band change by the simple actuation of three switches. In its design, space has been conserved; however, size has not been restricted at the expense of efficiency, reliability, or signal quality.

Quite common in the 1930's and 40's was the push-pull output circuit using two tubes, a balanced tank circuit, and link coupling, well known for its high efficiency and for cancellation of even order harmonics. The grounded grid circuit was known but not commonly used. In this amplifier, the balanced tank circuit is adapted to use with a single 4-1000A tetrode, used in a grounded grid, grounded screen circuit with link coupling. Harmonic distortion products are minimized. Efficiently tuned and correctly matched input circuits are used to improve signal quality and reduce drive requirements. The 4-1000A is run at an efficient plate voltage and loafs at a kilowatt dc input.

System

Fig. 1 is a block diagram showing the functional arrangement of units for power supply, signal amplification, and antenna matching. The amplifier input and output circuits are continuously tunable across the 80, 40, and 20 meter bands. A tuned link for each band feeds the output to separate antenna tuners for 40 and 20 meters, which in turn feed 95 Ohm balanced coaxial lines. The 50 Ohm unbalanced input to the antenna tuning unit is fed straight through on 80 meters to a 50 Ohm unbalanced line.

Sixty seconds is allowed for filament heating before high voltage is applied. For tube protection, the high voltage is removed from the tube when plate current ex-

ceeds a value which has been preselected by the operator. Simultaneously, exciter drive is transferred to the antenna tuner (still correctly matched to the exciter output) and the VOX relay is rendered inoperative. The sixty-second time delay then recycles, the antenna is transferred back to the amplifier, and plate voltage is reapplied together with exciter drive. If a fault continues to exist, the system will continue to recycle until operator intervention occurs.

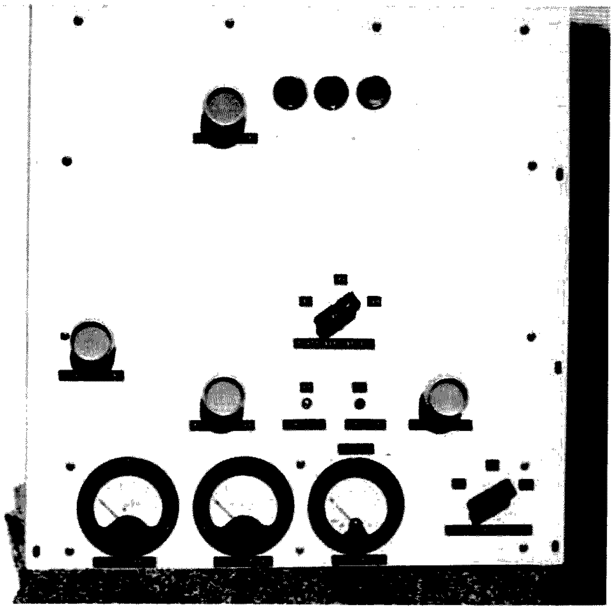
A large capacity heavy-duty blower is contained in an enclosed box at the bottom of the amplifier cabinet. An air filter is provided. Air from the blower is discharged into a plenum chamber and thence through a flexible hose to the pressurized amplifier chassis. Separate meters provide full monitoring of the tube voltages and currents. The system is contained in a 23" wide by 24" deep by 62" inch high metal rack cabinet mounted on casters. Total weight is 450 lbs. Cost, including 2 4-1000As, is $350.

Input Tuned Circuits

The input circuits are shown in the Fig. 2 schematic. Table 2 contains the values of all components and the number of turns for inductances. The input circuits are series tuned by means of small broadcast type variable capacitors. Variable capacitors provide a straightforward method of correctly adjusting the networks to a correct impedance match between the line and the cathode to grid load of the tube at the selected resonant frequency. Considerable interaction exists between components of the tube input circuit, and fixed capacitors are not recommended as a means of establishing correct tuning. The input capacity of the 4-1000A is a nominal 27 pF and series tuning works well in this application. Qs of the tuned circuits vary from 1.5 to 3, and once the input circuits are tuned to the band center (or other selected frequency), they need not be readjusted. The 20 and 40 meter coils are number 14 DCC (double cotton-covered) wire, close wound on 1½" diameter coil forms. The 80 meter coil is number 22 DCC wire wound on the same size form. The input line winding is wound on top of the cathode winding starting at the cold end of the coil, which is the end to be connected to the tuning capacitor. Allow enough dangling wire to make connections to the tuning capacitors and to the selector switch S1.

The only practical means of evolving the input tuned circuits was found to be one of cut and try. Originally, the input circuit values were calculated for Qs of two, and a complete subassembly consisting of the three coils, six tuning capacitors, and switch S1 was built up on a sheet of 1/8" aluminum. The subassembly was then tested using the following procedure:

A load of 100 Ohms in parallel with a 30 pF capacitor was connected from S1B (see Fig. 1) to ground. The ANT terminal of a noise bridge was connected from S1A to ground and a receiver S-meter was used to measure signal strength versus resonant frequency for a 50 Ohm line input. The inductances were tailored to resonate at the band center. After the amplifier was built, it was found that the input circuits would not resonate correctly and that the input impedance values were far from the 50 Ohms desired. The input subassembly was removed and, with the tube in its socket and a 100 Ohm resistor connected from one side of the filament to ground, the input impedance of the complete input circuit was measured with the noise bridge. The impedance was found to be 135 Ohms at 3.8 MHz, 120 Ohms at 7.2 MHz, and 85 Ohms at 14.2 MHz, rather than the 100 Ohms I had expected it to be from the manufacturer's data for the tube. The published data is the dynamic load impedance only of the tube.



Amplifier panel showing controls. 80 meter tune at top, 80 meter link tune extreme left, 20 meter tune and 40 meter tune centered left and right of plate bandswitch with screwdriver adjust link tune between plate knobs. Cathode band select at lower right. Meters from left to right are plate current, grid current, and filament voltage.

At this point, I resorted to the cut and try approach. Inductances were varied until resonance was obtained at the desired frequencies with close to a 50 Ohm load presented to the exciter line input connection. It was learned that one cannot obtain a given value of Q at a chosen resonant frequency and match a tube input load to a 50 Ohm input line impedance when using fixed coupling. This is the reason that the Qs vary from about 1.5 to 3, as previously mentioned. However, the Qs are quite acceptable, and the amplifier is very easily driven. The variable capacitors were found to be invaluable in evolving the input networks and in tuning them.

Output Tuned Circuits

The plate tank circuits are balanced and use split-stator grounded rotor capacitors. The Qs of each half of the resonant circuits are a nominal 6. The output links are series-tuned circuits having Qs of about 3. The links of this amplifier were made variable for the 20 and 40 meter coils and fixed for the 40 meter coil; however, it is suggested that the 40 meter plate coils be air wound and a swinging link used in lieu of the fixed link. I experienced the same impedance matching problem with the fixed link as previously discussed for the input networks. The impedance of the 40 meter output link ended up at 40 Ohms instead of 50 for the selected Qs. The swinging links are a pleasure to use. If the impedance presented to the line is incorrect, the coupling is increased to raise it, or decreased to lower it. In the photographs, the 80 meter tank coil is suspended upside down. The 20 meter tank is the large wire air wound coil on the right side looking from the back. The 40 meter tank is on the left side. Mounting method for the supplementary 50 pF fixed vacuum capacitors used with the 80 meter variable capacitor can be seen at the extreme right.

Output Coil Construction

The entire 20 meter coil is 12 continuous turns of number 4 soft drawn copper wire. It is close wound over a 3" diameter tube and the coil allowed to spring to about 3-1/8" inside diameter when winding tension on the wire is relaxed. The center turn of the coil is spread to a pitch of 1¼" so that the link will swing in and out from one side. The remaining turns are spread so that the overall coil is 5½" long. Large soldering lugs are used to connect the coil to the variable capacitor and the coil is supported on a 3/8" x 1" x 9" long plexiglas strip. This size plexiglas strip is used to replace the aluminum top bar on the National Model AMT split-stator capacitors in all three tuned circuits. The 20 meter coil can be easily silver plated using Cool Amp silver plating powder. Plating instructions are printed on the container (see Reference 1). The 20 meter link is 4 turns of #16 wire, 2½" OD x ½" wide. The link is silver plated and is mounted on a plexiglas strip off the capacitor frame for pivoting. The entire 40 meter coil is 19 turns of #10 enameled wire 3" OD (outside diameter) x 3¼" long wound on a ceramic form. The 5 turn link is wound over plexiglas strips cemented to the wire. The link is 3-3/4" OD x 7/8" long. The 80 meter coil is wound in two sections. Each section is 17 turns of #10 wire, 3-7/16" OD x 3" long. Close wind the coil on a 3" OD tube and allow it to spring out when winding tension is released, then insert three 1/8" x 1/4" x 5" strips between the 3" tube and the inside of the coil spaced equally around the diameter. Wind .06" diameter insulated flexible wire around the form over the strips, as spacers between the coil turns. Stretch the spacing wire tight enough that it forms a straight line between the spacing strips and the result will be a clearance space between coil turns and the spacing wire at three locations around the circumference of the coil. Plexiglas strips 1/8" x 1/4" x 3-1/8" long can now be cemented to the outside of the coil wires using DuPont Duco Cement. Let dry overnight, then slide the spacer strips out and remove the coil from the tube. The spacer wire will fall out on the inside of the coil and more Duco cement can be applied across the plexiglas strips from inside the coil to complete the job. The two coils are cemented to a 3/8" x 2" x 9" long plexiglas strip so that the center line of the coil is offset 1-1/4" from the capacitor shaft center line when the coil is mounted on top of the capacitor. This construction allows the capacitor to be placed close to the chassis edge yet spaces the coil away from the metal enclosure. A two inch space is allowed between coils at the

40 meter tank at left, 20 meter tank at right bottom, 80 meter assembly right top. One of the two 80 meter fixed capacitors is visible at right top. The box at top center contains the plate rf filter assembly. The three small angles around the tube socket center the chimney.

center for the swinging link. The link is 8 turns of #10 wire x 1-1/2" long of the same diameter and construction as the main coils. A piece of 3/8" x 1" x 3" long plexiglas is filed to the coil radius and cemented to the coil as a swinging arm. The arm is supported from the chassis on a 1/8" x 1" aluminum bracket as a pivot support.

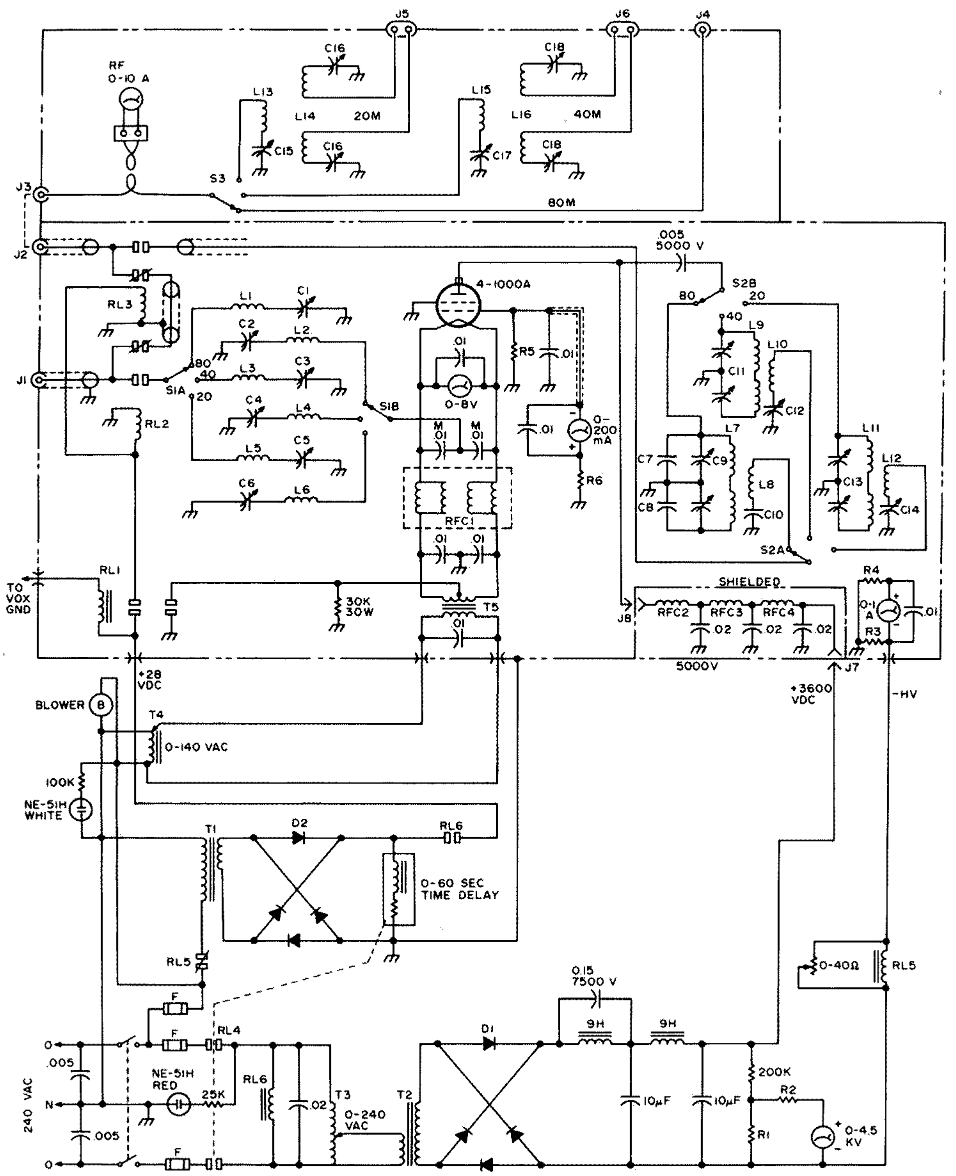

Fig. 2. Amplifier schematic.

Antenna Tuners

The antenna tuners use commercial coils: Johnson 500 HCS40 on 40 meters and Johnson 500 HCS20 on 20 meters. Although these are 500 Watt coils, they are more than adequate for use in a series-tuned 1 kW circuit. The antenna tuner links are fixed. They are cemented to plexiglas strips and supported from the main coils at the center of the main coils. These links are #16 wire of 2-1/2" OD, 4 turns (3/8" long) on 20 meters, and 8 turns (3/4" long) on 40 meters. If you wish to wind your own, simply duplicate the 40 and 20 meter plate tank coils, except #10 wire may be used for the 20 meter coil instead of #4 wire, if desired. An advantage of the #4 wire is that the coils are self-supporting and very simple to make as compared to the #10 wire coils reinforced by plastic strips. The variable capacitors used for tuning the plate and antenna tuner links should have a minimum spacing between plates of 20 thousandths. Screwdriver adjustable types are suitable since they need only be tuned occasionally. The split-stator capacitors used in the antenna tuner output circuits can be of 20 thousandths spacing if series tuning is used, as in this tuner. If the flexibility of parallel output tuning to match high impedances is desired, use a capacitor having plate spacing of at least 1/8 inch.

Metering

Filament voltage, plate voltage, grid current, and plate current are indicated by means of separate meters. The advantage of separate meters is that overall performance of the amplifier is apparent at a glance and, particularly, grid and plate current can be monitored simultaneously.

The grid must be held very close to ground potential to avoid the generation of high frequency parasitic oscillations. The most commonly used method of accomplishing this and yet of obtaining an accurate measurement of drip current is to raise the grid slightly above ground potential by means of a low value resistor and to measure the voltage drop across the resistor (as grid current flows through it) by means of a voltmeter calibrated to read grid current. Mock up the grid metering circuit consisting of R5, the meter, a variable dc voltage source from grid to ground, a variable resistance in place of R6, and a second milliammeter in series with the grid current meter. Vary the supply voltage and the variable resistance to arrive at tracking of the two meters. Measure the value of R6 required and substitute a fixed value.

The filament voltage meter leads are connected directly to the tube socket for accuracy of measurement. Shielded wire runs from the socket to the meter. Use a one percent accuracy meter for this application.

The values of resistance required for plate voltage and current metering can be calculated simply and accurately. For example, assume that plate voltage is to be measured using a 0-15 milliammeter with the legend on the meter face changed to read 0-4500 V dc. Then 15 mA must flow through the

Dc Plate Voltage	3600
Ac Filament Voltage	NOMINAL 7.5 (7.13 to 7.87)
Filament Current	22.7 Amps. MAX.
Zero-signal dc Plate Current	110 mA
Single Tone dc Plate Current	685 mA
Single Tone dc Screen Current	90 mA
Single Tone dc Grid Current	160 mA
Single Tone Driving Power	115 Watts PEP
Driving Impedance	105 Ohms
Load Impedance	3050 Ohms
Plate Input Power	2470 Watts PEP
Plate Output Power	1725 Watts PEP

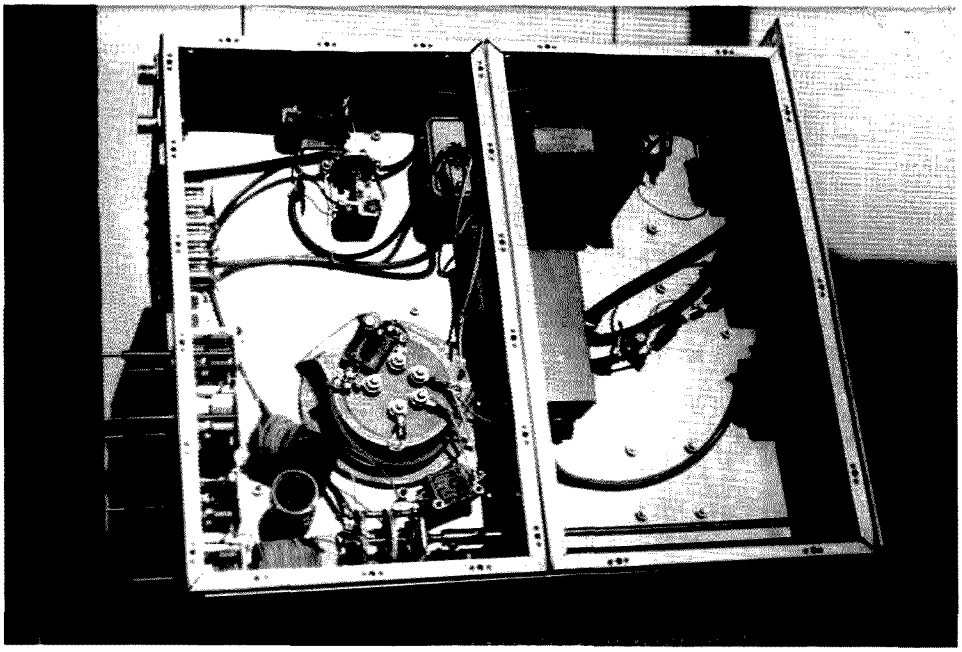
Table 1. 4-1000A characteristics.

meter for full scale reading. Choose a value for R1, assume 4500 V dc output from the HV supply across R1 in series with the bleeder resistor, and, using Ohm's Law, calculate the value of R2 required to allow 15 mA to flow through the meter. A little trial and error is necessary with this method, but the calculations go very rapidly using a low-priced calculator.

A 0-10 milliammeter was used to measure plate current. The legend on the meter face was easily changed to read 0-1 Ampere. Since 10 mA of the one Ampere must flow through the meter and R4 when 990 mA flow through R3, the value of R4 is easily calculated once R3 is assumed. A series milliammeter can be inserted in the circuit to check accuracy of the plate milliammeter.

Cooling

Cooling requirements are graphically depicted in Fig. 3 in terms of blower air flow, static air pressure, and operating frequency. For application of the tube below 30 MHz, use the 30 MHz values of 20 cfm of ambient air flow required into the pressurized chassis, under which conditions the static pressure drop across the tube socket and tube in its chimney is 0.6 inches water gauge. The blower must be capable of supplying the air at 0.6" pressure as a minimum. A good-sized blower is needed to cool the 4-1000A if the blower is to run at a slow speed for quiet operation. The surplus blower used in this amplifier is a Torrington AD508 Airrotor having two 5" diameter x 3" long rotors with forward curved vanes. The blower is belt-driven by a ¼ HP motor. The air discharges into a sheet metal box and the 2½" diameter flexible hose which carries air up to the pressurized amplifier chassis connects to the box at the rear of the cabinet. Automobile air conditioning hose is suitable for conducting the cooling air. The only constraint on the plenum chamber (box) is that the distance from the forward edge of the blower wheel to the side of the box opposite the wheel discharge be about 5 to 6 inches. This particular blower supplies the required air when running at 1400 rpm. It is being run at 2150 rpm because doing so only required reversing the belt pulleys, and the extra factor of safety in cooling air supply yields a conservative operating condition. On the amplifier chassis, bring the cooling hose connection in at a point remote from the cooling inlet to the socket, and, if you use the Eimac SK500 aluminum socket as I did, cut off the entire air inlet tangent to the machined circular surface to increase the efficiency of air flow. In addition, drill ten ½" diameter holes through the socket side wall to admit air.



Bottom of chassis showing switching relays at top left, feedthrough filters and input tuning capacitors at left. The right half of the chassis contains the meters, filament transformer, and filament choke. Note the advantage of the two chassis arrangement for shielding.

Power Supply

The power supply section contains the components indicated on the schematic. It is of conservative design using parallel resonant choke input followed by one section of brute force filtering. The first section is tuned to the main ripple frequency (120 Hz) and presents a sufficiently high impedance at this frequency such that a low bleeder current of 20 mA provides good no load to full load (500 mA) regulation. The low bleeder current conserves power and avoids a problem of bleeder heat in the equipment cabinet. The HV rectifiers are silicon stacks (see Table 2) and were obtained from R.E. Goodheart Co. (see Reference 2). If you build up your own, a peak inverse voltage rating of 5650 volts is necessary at 140 mA average current using bridge rectification. The rectifiers are mounted on a sheet of aluminum which acts as a heat sink. The 28 V dc relay supply, protective relays, and terminal board are submounted on a 5" x 8" x 1½" chassis from the ¼" x 20" x 20" aluminum plate which supports the overall supply. The plate is mounted in the rack at four corners using steel angles. The power supply panel is 19" x 12" high. It contains the on/off switch, fuses, panel lights, HV voltmeter, and the two variacs. More filter capacitance has been used than is absolutely necessary. A capacity of 4 uF from each choke section to ground is about minimum for a 3600 volt supply used on SSB. Fig. 4 shows the power supply regulation.

Mechanical Construction

The amplifier box is 17" wide x 20" deep by 20" high.

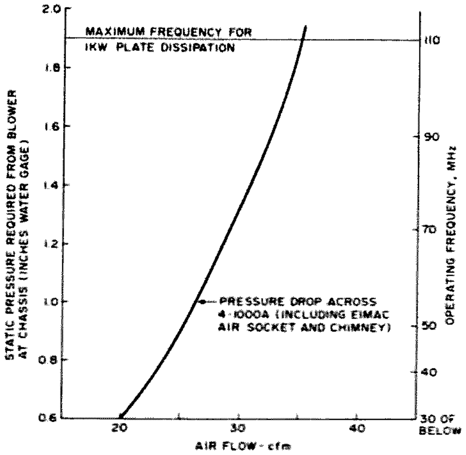


Fig. 3. Cooling requirements for 4-1000A tetrode using Eimac air socket and chimney at 1000 Watts plate dissipation.

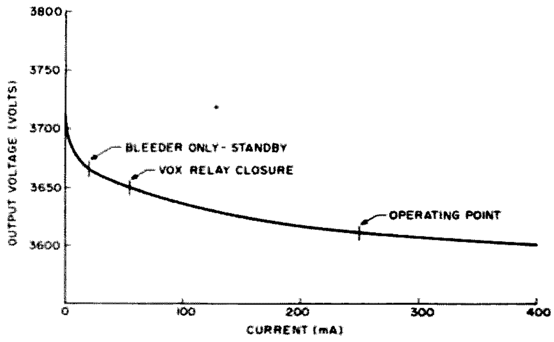

Fig. 4. HV power supply regulation.

It is made up of aluminum top and bottom chassis held together by four aluminum panels – front, back, and two side – plus one 17" x 20" bottom plate. The bottom chassis is made up of two 10" x 17" x 4" deep chassis fastened together by means of number 8 machine screws. The top chassis is made up of two 10" x 17" x 2" deep chassis fastened together. I could not obtain 17" x 20" chassis; hence, this construction. The top chassis is turned upside down, presenting what would be the normal chassis top surface to the inside of the box. Four ¾" x ¾" x 14" aluminum angles are mounted vertically between the top and bottom chassis to support the front and back panels and to form an rf tight enclosure. The side and front panels are fastened using through machine screws with nuts and lock washers. The back panel and bottom plate are held in place by means of number 8 nut plates.

The meters are mounted in the front of the lower chassis, which simplifies shielding and wiring. Since the meter holes extend through both the chassis and front panel, it is advisable to fasten the front panel to the chassis and then cut the meter holes straight through using a hole cutter of the adjustable arm type. The chimney for the tube is held in position by three 1/2" wide pieces cut from 3/4" x 3/4" x 1/8" aluminum angle. Allow 1/32" clearance between the angle and the glass chimney to allow for expansion. The input networks and selector switch are submounted on a sheet of 1/8" aluminum. The filter network for the HV, which consists of RFC2, RFC3, RFC4, and three .02 microfarad capacitors, is contained in a 5" x 5" x 4" box. J7 and J8 are insulated binding posts mounted in the box prior to wiring. Ten 1" diameter holes are drilled in the back panel to discharge air from the tube compartment. Aluminum screen wire can be used for shielding over the holes, or one inch diameter screened inserts can be purchased. The inserts contain tabs which are bent over to hold the insert in place in the hole. All shaft extensions are 1/4" diameter brass. Panel bushings are used for all front panel control shafts. All controls and meters were labeled using a Dymo tape marker obtainable in most drug stores. The entire rack and all front panels are painted with low-gloss off-white enamel. The aluminum panels were given one coat of etching undercoat prior to enameling. This is necessary so that the paint will adhere to the aluminum. Air leakage from the pressurized chassis must be minimized by use of a gasket between the bottom plate and the chassis. I used a sheet of plastic covering the entire bottom plate and cemented it to the plate in a few places to hold it in position. Using a sheet the full size of the plate is much easier than cutting a gasket to the width of the chassis flanges and then trying to position it properly for alignment with the holes in the chassis. Three one-inch holes containing shielding inserts are cut in the front panel for viewing the tube.

Practices of importance in rf amplifier construction are as follows:

1. Ground components directly to the chassis by the shortest route. Do not use a single point ground.
2. Use coaxial connectors and feedthrough capacitors or filters to bring conductors into the enclosures. Sprague 0.01 uF high pass capacitors are good as are a number of surplus line filters.
3. Use shielded wire for filament, power, and metering leads inside the amplifier chassis.
4. Use 0.01 or larger filament bypass capacitors. Use mica capacitors for the two marked M on the schematic.
5. Keep the lead from the plate cap to the switch and from the switch to the plate tuning capacitors as short as possible to minimize parasitics. The leads from the plate tuning capacitors to their respective coils can be longer, although if the construction practice used here is followed, they will be quite short.
6. Place coils at least one coil radius away from metal panels to keep eddy current losses at an acceptable level. The end of the plate coils opposite from the plate lead are intentionally placed ¾" from the adjacent metal panel to provide a 8 pF capacity to ground to balance the output capacity of the 4-1000A.

Tuning

Tuning of the amplifier input and output networks and adjustment of the antenna tuner is performed at this QTH using an antenna noise bridge. The following procedure is used. Remove the amplifier from the cabinet and remove the bottom plate. Place the 4-1000A in its socket and connect the lead to the plate cap. Connect a 3000 Ohm non-inductive resistor from the plate connection at S2B to ground. Connect a 100 Ohm non-inductive resistor from one side of the filament at the socket to ground. Connect the noise bridge antenna jack to S1A at the exciter input line connection points using leads as short as possible. Place S1 in the 80 meter band select position. Set the receiver (which is connected to

Table 2. Component list.

the noise bridge) to the band center or other frequency at which it is desired to resonate the amplifier input network. Set the bridge to 50 Ohms and rock C1 and C2 to minimum dip of the receiver S-meter. Repeat the procedure for the 40 and 20 meter input networks.

Connect the noise bridge ANT terminal to the antenna connection (J2) of the amplifier. Apply 28 V dc to RL1 to actuate RL2 and RL3, or close RL2 and 3 mechanically so that S2B is connected to J2. Set S2 to 80 meters. Set the receiver to the band center or other frequency at which it is desired to resonate the 80 meter output network. Set the bridge to 50 Ohms and rock C9 and C10 to the minimum dip of the receiver S-meter. Tune the 40 and 20 meter networks in a similar manner.

Connect the antennas to the antenna tuner and the bridge ANT terminal to J3. Set the bridge to 50 Ohms and S3 to the 20 meter position. Tune C15 and C16 for a dip. Repeat for the 40 meter antenna. This completes the tuning procedure. Remove the 100 and 3000 Ohm resistors. Replace the bottom cover, replace the amplifier in the cabinet, and connect up all cables and the cooling hose.

Operation

In operating the amplifier, set S1, S2, and S3 to the desired band, check that the two variacs are turned to zero, turn on the power, and bring the filament up slowly to 7.5 volts. When the 60 second time delay actuates and the red panel light comes on, turn up the plate variance to 3700 volts reading of the panel voltmeter (HV will drop to 3600 under load). At this point, the plate and grid current meters will read zero. Actuate the VOX relay by grounding the VOX lead to the exciter. Grid current will read zero and plate current will read about 55 mA. With the exciter in the CW tune position, turn up the exciter drive control until the plate current meter of the amplifier reads 260 mA and grid current reads 50 mA. Allowing for feedthrough power from input to output, the input power to the plate circuit is now just under one kW for CW operation.

Grid current for single tone input runs 70 mA with plate current at 280 mA. The SSB input for this condition is 1 kW PEP. To correctly adjust the amplifier for 2 kW PEP, a two tone generator is required. If you do not have a generator available, adjust the amplifier for 2 kW PEP input by talking into the microphone at your normal voice level and distance from the microphone and increasing the drive until the plate meter peaks reach 265 mA. Grid current peaks will be about 60 mA for plate current peaks of 265 mA. The actual current peaks are approximately double the values of the meter readings. Table 1 shows maximum tube ratings at a plate voltage of 3600 V dc. ■

Build a $2 Drill

-- and put your razor to work

If you need to drill small holes, this little motor is handy and inexpensive. It easily drills through 1/8" of bakelite, fiberglass or aluminum. It beats putting a #60 (.040") drill in a motor and immediately breaking the bit. Small sizes need speeds up to 7000 rpm or more.

The following describes conversion of Sunbeam "Shavemaster" razor motors into useful hand-held drills. Model "W" seems to be plentiful at local salvage stores of Goodwill Industries, St. Vincent dePaul and Volunteers of America, at prices from 15¢ to 50¢.

The procedure is as follows: Remove two screws from the bottom of the plastic case and lift out the works. Brush off any dust and clippings. Remove the retaining washer from connecting rod and take off the nylon rod. Remove 4 screws and discard all oscillating shaver parts, but retain the large diecast plate.

Unsolder two wires from ac power input post.

Remove two brush holder clips, keeping your fingers over the holes to prevent the brush springs from flying away. Remove the 4 hex nuts holding the end bell to the motor frame. Slide out the armature.

Carefully remove the two motor brushes. If they are less than ¼" in length they should be replaced (shaver repair stores have them). Brush out carbon dust, etc.

Place the armature in a vise and unscrew the crank (counterclockwise). Discard the crank. Run a 4-40 tap into the hole in the shaft. This is preferably done in a metal lathe but can be successfully performed by hand. On the reverse end of shaft, saw a screwdriver slot with a miniature hacksaw blade. File off any burrs left by the saw.

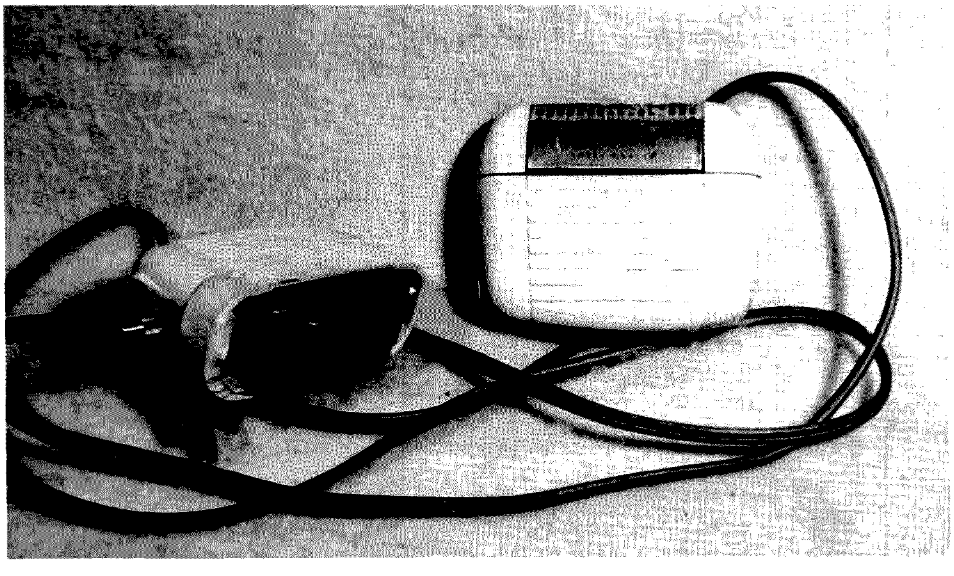
Place a drop of oil on each bearing and, if there are spacer washers on the shaft, put at least one on the commutator end for a thrust bearing. Reassemble the motor and solder the wires back on power input post. Now, test the motor.

Take the plate saved from shaving mechanism and saw off the bosses or projections that held the shaft. File it smooth, and round off all corners and edges as you hold this in your hand after assembly. Replace on the motor frame.

Drop the motor back in the plastic case and measure points on the housing even with ends of the armature shaft. Drill ¼" holes in each end. Enlarge the crank opening to ½", preferably with a tapered reamer, as it is very easy to split plastic with a large drill.

Obtain a steel 4-40 machine screw about one inch long, and cut off the head, leaving it about ¾" in length. Smooth the threads in a 4-40 die if possible. Screw this into armature shaft.

If you have the original power cord with the special



plug, put the motor back in the case. If the cord is not available, use an ordinary lightweight zip cord and solder it onto power post.

Purchase from your local hobby store a No. 22B-C X-Acto drill chuck adapter. If not available in your area, you can order the chuck from X-Acto Corp., 48-31 Van Dam St., Long Island City, New York 11101. This size chuck accommodates No. 63-50 drills.

Place the chuck shaft in a 3 jaw chuck on a metal lathe and tap it with a 4-40 tap about 3/8". This can possibly be done by hand, but risks going in crooked and breaking the tap.

File two flat places on opposite sides of the shaft where the X-Acto name is stamped. I made a small wrench from a scrap of 1/8" steel to fit the flats. Screw the chuck onto the armature shaft, holding it with a screwdriver in the slot. Put a small drill in the chuck and tighten it with your fingers, holding the chuck shaft with a wrench.

Plug it in and put it to work. This gadget is quite useful for cleaning out solder from holes in circuit boards which have had parts removed.

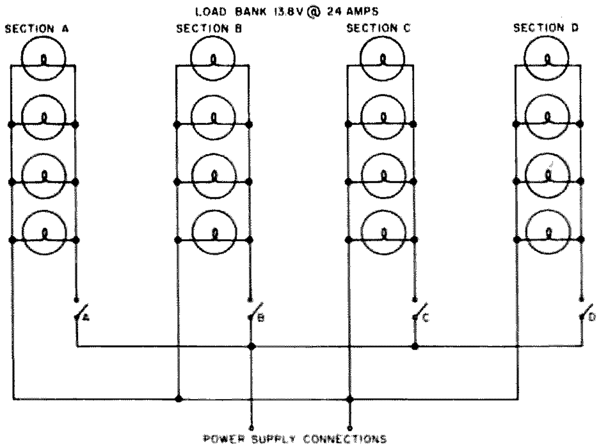
If desired, a push-button switch can be made using the hole over the power post. This is not easy, but does make it more convenient. It is necessary to make a plastic push-button on a lathe. Drill a hole in it to slip over the concentric power post. I took contacts off a small discarded relay and soldered them onto the power post terminals, so that the button pressed the contacts together. Then one wire to the motor is disconnected from the post and goes directly to the power cord (which comes in from a new hole drilled in the opposite end of the plastic case). The other wire goes in series with the switch contacts. ■

Unique Power Supply Tester

- - uses a load bank

James C. Chapel W9HDA
2349 Wiggins Avenue
Springfield IL 62704

The first question asked might be, "What is a load bank?" The term is taken from the electrical power industry to explain a device to simulate a load on various power sources in order to check the load performance of those sources. In this case, the article covers the building of two simple load banks or dummy loads for small and rather large sized dc power supplies that are finding present usage with hams and hobbyists. This article shows how it can be done economically and with readily available parts. Also, using the basic ideas presented here, load banks for most any type of low voltage power supply can be built.



Section	*Load*	*Current in Amps @ 13.8 volts*
A	*33%*	*8*
A & B	*66%*	*16*
A, B, & C	*full*	*24*
A, B, C, & D	*133% of full*	*32*

Fig. 1. All bulbs #1073. All wire #14 TW. A, B, C, D – 10 Amp relay contacts or 10 Amp switches (optional since connections can be made directly).

In order to properly evaluate the performance of a power supply (whether home built or commercially built), the supply must be tested at various degrees of loading – that is, no load, half load, full load, etc. The major requirement for a suitable load bank is that it be capable of providing these various load conditions. Thus, several load elements are required, or at least one large variable element is required, in order to cover several different load conditions. These load elements would typically be large fixed or variable power resistors. If the power supply is of any size, the load elements have to be of high power rating (10, 25, or even 50 Watt). A look at a parts catalog will show that power resistors get expensive as the power rating goes up and the different ohmic values available go down. Also, power resistors present the problem of how to get rid of the heat and how to conveniently mount the resistors.

Instead of using the regular power resistor in the design of these load banks, automotive bulbs and pilot lamps were used. These are readily available at auto parts stores, electronic parts houses, and even department store electrical parts sections. Bulbs are selected on the basis of voltage and current requirements and typically work out very nicely in regard to both values. The problem of power dissipation is very minimal and mounting can be very simple. With the load elements decided, the actual construction of the load bank can begin.

The first load bank requirement was for a rather large 13.8 volt dc 24 Amp dc supply. It was decided to check one third, two thirds, full load, and 133% of full load. Voltage and ripple were observed under the various load conditions. The #1073 automotive bulb was selected with a nominal rating of 12.8 volts @ 1.8 Amps. Typical cost is less than 30¢. Since the power supply voltage was to be a volt higher, the current at that voltage was approximated to be about 2 Amps. This is a fine feature of these bulbs – the voltage can be increased up to 20% of nominal rating without any problem in this application.

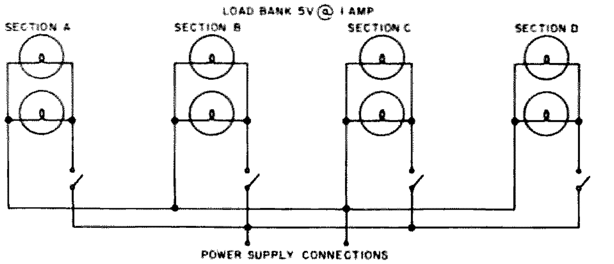
The bulbs were arranged in four groups or sections of four each. See Fig. 1 for the circuit diagram. Each group presents a load of about 8 Amps at nominal voltage to simulate four load conditions. In order to keep costs down and construction simple, the wires consisting of #14 TW wire were soldered directly to the bulb bases. The start and end of each section wire were wrapped around a nail which was driven into the wooden base board. This eliminated expensive sockets and, after all, a load bank is not a device that is normally on display in the shack.

Since this load bank was to be used for a considerable

amount of testing and since four surplus relays were available, each load section was wired through relay contacts as shown in the diagram. Any combination of loading can be quickly selected. This extra feature can be eliminated with just the use of solder connections or switches with proper current rating. The switching feature is certainly handy if considerable testing is to be done, but adds considerably to the parts cost if the junk box is not well stocked.

The second load bank was for a much smaller dc power supply with a rating of 5 volts @ 1 Amp. Following the same design features of the previous load bank, a #502 bulb was selected as load element in four sections with two bulbs in each section, giving 30%, 60%, 90%, and 120% of full load. Since the current requirements were much less, about 0.3 Amps per section, regular #22 solid hookup wire was directly soldered to the bulb bases and toggle switches (or even slide switches) used for controlling the load sections. A small wood base board was again used for mounting the bulbs and wiring with a small 1/8 inch pressed board panel (nailed to the edge) to support the switches. This supply is most useful for checking logic power supplies used with ICs. Overload or current foldover characteristics can be checked on supplies designed with that feature. See Fig. 2 for the circuit.

There are many advantages to these simple load banks besides the cost and ease of construction. The bulbs present a large amount of light under full load to leave no doubt that the supply is working. Also, there are no burn marks from power resistors on the workbench or, even worse, the dining room table. Buying the bulbs by the box reduces cost, and automotive type bulbs are readily available, even at gas stations.



Section	*Load*	*Current in Amps @ 5 volts*
A	*30%*	*0.3*
A & B	*60%*	*0.6*
A, B, & C	*90%*	*0.9*
A, B, C, & D	*120% of full*	*1.2*

Fig. 2. All bulbs #502. All wire #22 solid. A, B, C, D – 0.3 Amp switches.

The purists may argue that the bulb is not a constant load resistance due to the filament characteristics. This sudden heavier than normal load when voltage is first applied to the bulb is very short in duration and provides an even stricter load test of the supply being tested.

The load bank ideas presented here can be extended to other sizes and types of load banks by changing the bulb types and the number of bulbs in a section, and even the number of load sections.

These load banks have been used to check voltage and ripple conditions on a variety of home brew and commercial supplies. The cost is certainly cheap if proper shopping around is done on the choice and source of bulbs. ■

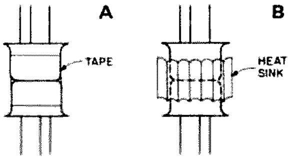
Instant Spares

-- for those after-hour repairs

The time required to restore failed equipment depends often on locating the spares. The simple scheme described insures that replacement plug-in devices are always available at the exact point of need.

Fig. 1. Self-storage of spare TO-5 devices. (a) Bonding with transparent tape. (b) Bonding with a common heat sink.



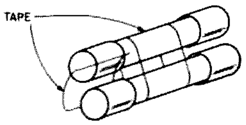


Fig. 2. Cartridge-type fuses, bonded with transparent tape.

The method is to combine the operating unit and an identical spare into one double-ended package. The example shown in Fig. 1(a) joins a pair of identical transistors back-to-back, using transparent tape, so that identifying data remains visible. TO-cased devices requiring heat sinking may be joined using only the heat sink as in Fig. 1(b).

When equipment failure occurs, the plug-in packages are simply flipped over one at a time, to isolate the problem to the device or other components.

Equipment using several identical plug-in units may not justify the cost of a spare for every socket, and a lesser quantity would be adequate.

Many other plug-in units, ranging from DIP ICs, automobile fuses and flashers, to household plug fuses and fluorescent starters lend themselves to this sparing technique, as suggested in Figs. 2 and 3. ■

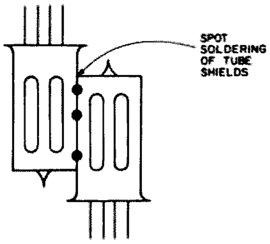

Fig. 3. Method of storing spare miniature vacuum tube.

Light Up Your Bench

-- versatile power distribution system

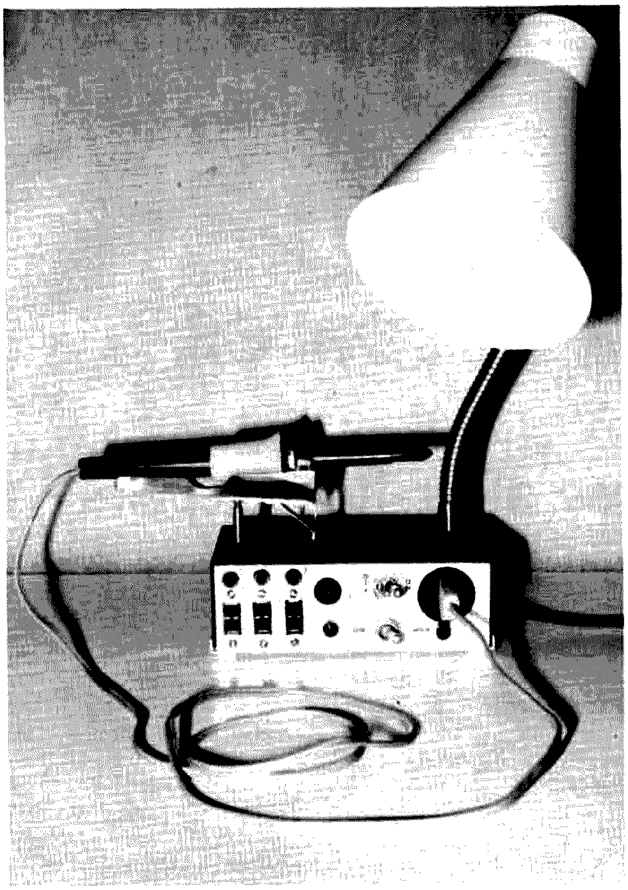
Joseph M. Frezza WA3VGT
499 Easton Road
Horsham PA 19044

My workbench becomes a mass of ac cords just about every time I dig into a project, leaving limited work space. In the middle of the confusion, I entertain the thought of constructing an ac receptacle that will be portable on the bench and at the same time have some fuse protection for equipment under repair or construction.

Another nagging workbench item is the soldering iron. It would be difficult to determine how many times it sat on the bench cooking for days, or how many times I accidentally burned myself or damaged material lying on the workbench.

Well, thanks to *73* and Arny WB4FDQ, I got off dead center and built my magic box. Now I have a portable switched 3 outlet ac power source with 2 of the outlets fused, directional control light source, soldering iron power source with high/low heat, and removable heat shield stand for the soldering iron.

This was another junk box project from start to finish. Selection of components is not critical as long as they can handle 115 volts at 5 to 9 Amps. In addition to the basic tools, a small punch set and nibbler were needed. If you don't have access for borrowing one, Lafayette Radio usually has them in stock at a modest price.



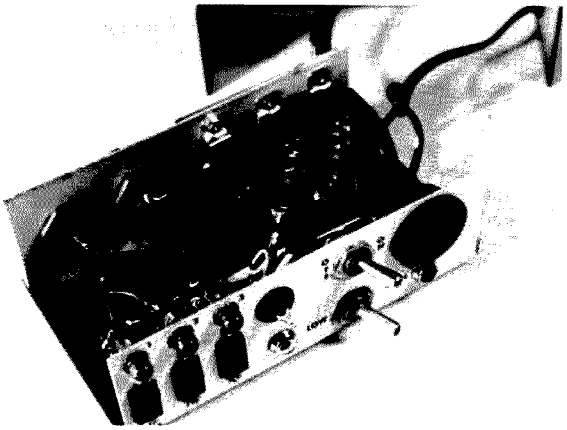
Workbench magic box with soldering iron in place and plugged in. Although the switches and fuses are on the rear panel, I elected to locate the indicator lights above the respective outlets. If the receptacle for the soldering iron was relocated to the left side panel, the cord might be easier to handle.

The project began with Arny's article and circuitry in *73*'s July issue. I did replace his S2 switch with a DPDT switch and eliminated the number one position as he suggested. In addition, I utilized a three prong safety cord to ground the case.

Fig. 1 is the schematic circuitry of the magic box. I decided I wanted a few luxuries not really needed. A neon indicator light is always on as long as the box is plugged in. The indicator lights for outlets 2 and 3 are wired behind the fuses to indicate when a fuse is blown. If the builder is working with very low current fuses, the indicator light load should be placed in front of the fuse so as not to increase the current drain at the outlet.

My aluminum case was 3" x 5" x 2" and was used in several earlier projects. I tried to place all the wiring in the lower half to simplify construction. The cradle microswitch support is the frame of a broken rocker switch.

The soldering iron cradle was constructed from sheet aluminum. The microswitch is operated by a plunger-type rear support. A standoff



Internal parts placement should allow working space for top cover microswitch assembly. The light unit had its own power switch, eliminating the need for a switch on the chassis.

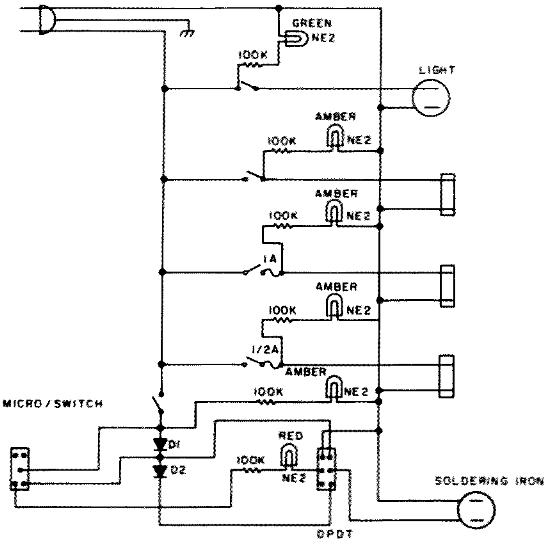


Fig. 1.

spacer with bolt for plunger works well. The plunger was designed with 1/8" travel, allowing plenty of movement to insure switch operation and still protect from excess weight being placed on the cradle.

The light source is an old desk lamp fixture. Placement of the light should allow free access of the soldering iron for right- and left-handed users. A high intensity light unit would make a better light source.

Parts placement is not critical.

With a little effort, your magic box can be made to look store-bought. Remove all dirt and grease from aluminum and use a good primer base. Aerosol lacquer spray paint is easily found in auto supply houses and hardware stores. I used rub-on lettering that I bought at the ham store and then sprayed with a clear lacquer for added protection. Painting and labeling should be done before component assembly. Allow a day or two after painting for finish to reach maximum set.

Don't let the simple wiring circuitry mislead you into not checking before attaching to ac line. The accompanying photos were supplied by Don Smith WA3VEA.

The completed project will provide invaluable service on or off the workbench. ■

Hang Ten

-- relay slow release circuit

John Skubick K8ANG
1040 Meadowbrook
Warren OH 44484

These are old phone company central office equipment circuits that are still used in today's modern electronic exchanges. Perhaps you may need only a slight or a very slight amount of delay-release in a relay(s) control circuit of yours. One way is to re-tension the relay springs by bending or "kinking." This practice (also used in C.O. equipment) is subject to the aging process and, with time, will change its characteristics. Here are two simple ways to have *stabilized*, short-delayed release in a relay.

The circuit in Fig. 1 gives very slight delays. The amount of delayed release is subject to the amount of current drawn by the coil and the coil's resistance.

Want a little more delayed release time for a given coil? Try Fig. 2. This one can be discernible to the naked eye in delayed releasing, dependent upon the coil current and resistance. Note the diode polarity; otherwise, you may end up with a short circuit!

"Ah-ha," you say, "but Fig. 2 is used to suppress the coil's inductive voltage kickback, for solid state or contact protection." That is correct! This is why sometimes electronic keyers can't follow high-speed sending when using reed relay outputs.

Maybe this bit of info will help solve your "knotty" relay timing problem(s)? ■

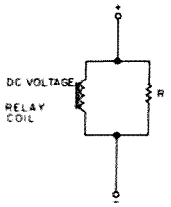

Fig. 1. Simple, compact, dc relay delay circuit. Shunting resistor should be five times the dc resistance of the relay coil. Wattage rating of resistor equals ¼ the power (in Watts) drawn by coil.

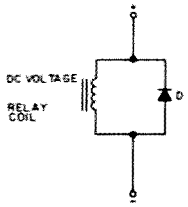

Fig. 2. Note polarity of shunt diode! Also observe diode's piv rating.

73 Magazine *Staff*

Using the Atlas Transceiver

-- practical experiences

The Atlas 180/210 series of transceivers has been used by now in every conceivable type of portable and mobile application from bicycle portable on up. This article presents a few operating notes and simple modifications for the transceivers which have been developed out of experiences using several of the units over the past year.

Fig. 1. A size comparison between a 210 and a Globe-Union battery pack which will power the unit at almost full power for several hours of intermittent operation.

For fixed station operation, the transceiver can be powered from anything from an automobile storage battery to one of the power supplies sold by Atlas. The automobile battery approach costs about $30 for a suitable battery plus the cost of a commercial or home brew charger. A standard Sears 60-80 Ampere/hour (20 hour rate) battery will easily keep the rig going for 4 hours of operation at full power. A relay can automatically switch in the charger. The advantages are a completely hum-free power source and a rig that is always ready, even if commercial power fails. The only disadvantage is the need to observe the usual requirements for ventilation, etc., when charging the battery. Home brew transformer type power supplies can also be built as long as they can supply 8 Amperes continuously and 16 Amperes peak while holding the output voltage between 12 and 14 volts. A minimum of 25,000 mF output filtering is necessary to keep hum at an acceptable level.

Moving towards portable operation, several power supply options exist. Atlas does sell a compact $100 110/220 supply which weighs about 15 pounds and will supply full power input. Some amateurs who have been willing to operate portable at the opposite end of the power scale have taken out the speaker in the transceiver and installed a simple 12 V dc supply in the space that will power the rig to a few Watts.

Also, the approach has been used for QRP portable, using a hefty wall plug type transformer and then placing the power supply filter components around the speaker (leaving the speaker installed) for portable operation where ac is available. However, for reasonable power output and true portability at an economic price, some form of rechargeable battery pack is probably best. Nicad batteries, if they can be found at a suitable price from a surplus outlet, are always a good bet. 4.5 Ampere/hour units (20 hour rate) will power the transceiver, although a heftier size up to 7.5 Ampere/hours is preferred. The Eveready or Gould rechargeable batteries being sold to power portable TV sets are a good economical approach. Lastly, one can use a gelled electrolyte type battery pack (such as the Globe-Union GC-1200 type, available from Burstein-Applebee at $60.00) which

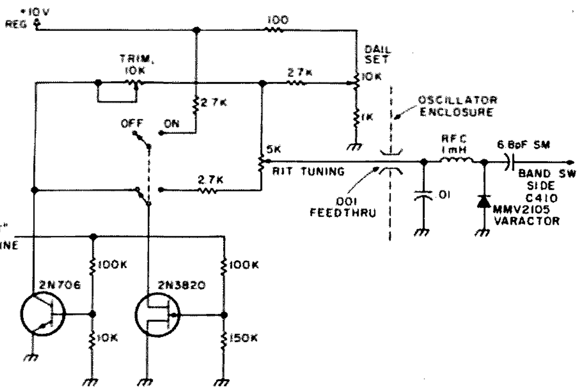

Fig. 2(a). This is the original RIT circuit developed for Atlas. Note the "Dial Set" capacitor is also replaced by a pot. With RIT on and RIT pot centered, zero beat calibrator signal with the "Dial Set" pot. With RIT off, zero beat signal with the 10k trimpot (mounted internally).

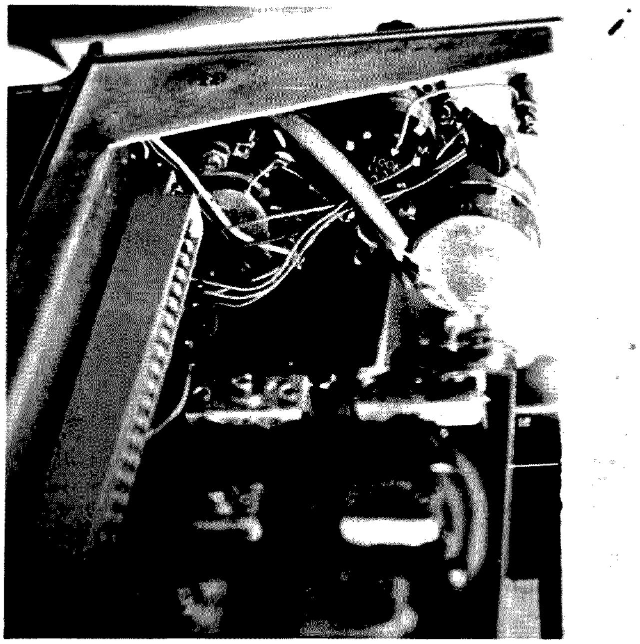

Fig. 2(b). This photo shows how the RIT potentiometer has been placed between the function switch and the ALC/MIC gain control. One of the trimpots for the RIT circuit is mounted directly on the potentiometer.

combines really compact size with good power capacity and a life of about 300/500 charge/discharge cycles. Such a battery pack is shown in Fig. 1 for a size comparison with the transceiver. The operating time that can be obtained from *any* battery setup depends on the input power level and the ratio of transmit to receive time. A QRP enthusiast can operate all night from a 4.5 Ampere/hour battery pack while, if using full power, the time would be about one hour. The microphone gain on the transceiver controls the PEP input level, of course, on SSB, but also the carrier level on CW. So, the decision is up to the operator as to the choice between operating time and the power input used.

Fig. 1 shows also an oversize tuning knob being used. The basic 15 kHz/revolution tuning rate seems to be convenient, but it is made even easier to use by a larger knob. A simple hole drilled partly into the knob with a large drill provides a simple "finger hole" for quick spin-type tuning across a band.

Improvements for SSB operation are hard to suggest for this rig. It has a fine sound on SSB and one of the sharpest filters used in an HF transceiver. But, a few simple items can improve operator convenience greatly. For instance, the aircraft pilot Plantronics type headsets, which essentially consist of a small transducer mounted over one ear with acoustic tube coupling for a pencil type microphone and a flexible tube fitting in the ear for a headphone, are now becoming available (see Godbout ads in *73*). These units are not cheap ($60), but they are excellent quality units, provide very sharp shaped speech response and, of course, provide complete "hands-free" operation. These headsets will be covered in some detail in a future article, but they are very easily adapted for use with the Atlas transceivers. Basically, the amplifier which comes with the headset need not be used, and the headphone element can be connected directly and the microphone element used via a 1k Ohm to 20k Ohm stepup audio transformer.

VOX is always a handy feature, especially for mobile operation. It can be added for $7.00! The key is the use of a simple Radio Shack "Science Fair" Voice Controlled Relay Kit no. 28-131. This kit is meant to be wired on a rather large perfboard moulded chassis, but it can be wired compactly on regular PC board and tucked in a corner of the transceiver. It was meant to be powered from a 9 volt battery, but operated well from the 12 volt line in the transceiver via a 220 Ohm dropping resistor. The kit, as it comes, has a sensitivity control, but not an adjustable time delay control. The latter feature is easily added by placing a 250k PC type potentiometer across C5 (the only 100 mF capacitor used in the kit). The relay that comes with the kit is wired to activate the PTT line. The first two stages of audio amplification used in the kit circuit can even do double duty as a microphone preamplifier, if desired.

Receiver Incremental Tuning (RIT) is one of those convenience features which can be debated on a transceiver. Obviously it is not needed for home station operation if a separate VFO console is purchased. It can be lived without for portable or mobile work, but it is handy to have. Atlas thought about RIT and paid to have a suitable circuit developed. But, how many controls, switches, etc., can you fit on the front panel of the Atlas rigs? For mobile operation, a noise blanker is a useful accessory, and Atlas opted to provide a front panel control for this accessory item. However, if the blanker is not installed, the available front panel space can be used to install an RIT circuit. The RIT circuit developed for Atlas is shown in Fig. 2(a). It is completely electronic. The MMV2105 varactor diode can be substituted by one from the Motorola MV series or even *some* ordinary 1N4001 rectifier diodes have worked. The original part, if you want it, is available for $1.50 from

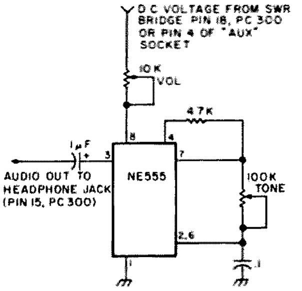

Fig. 3. The NE555 does it again, this time as a simple CW monitor for the Atlas transceivers with adjustable tone.

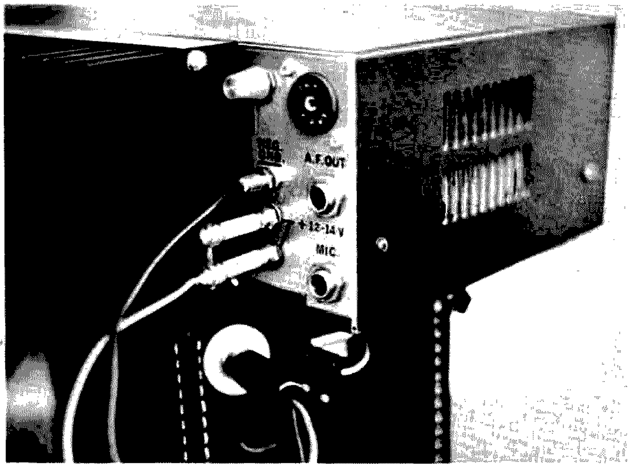

This photo shows how a miniature pot can be mounted on the rear panel as a volume control for the CW monitor of Fig. 3. It also shows the method of connection for the transceiver to a battery pack for portable operation.

Circuit Specialists, P.O. Box 3047, Scottsdale AZ 85257. The 5k tuning control provides a plus/minus tuning range of several kHz, although it is not uniform on each band. The tuning control is mounted on the front panel between the microphone gain and function switches. The photo of Fig. 2(b) shows how the potentiometer is mounted behind the front panel and how one of the PC type adjustment pots is mounted. Since only dc wiring is involved *outside* the oscillator enclosure, some liberty can be taken in the placement of the various components. Inside the enclosure, the varactor diode and 6.8 pF coupling capacitor must be securely fastened. A miniature DPDT toggle switch can be mounted any place panel space is available to turn the RIT on and off, on a 5k tuning point can be added with a switch to control a DPDT relay performing the same function.

The Atlas rigs are oriented towards the phone man, but they can make an excellent CW rig. In fact, for a rig so extremely well suited for portable emergency operations, it is a pity that the most fundamental mode of emergency communication, CW, wasn't a bit more emphasized. However, a few features to make CW operation enjoyable are easily added.

If one wants to go all the way, a complete electronic keyer can be built into the rig, such as the miniature Mini-MOS keyer described by WA6EGY in the Aug. 76 *73*. This keyer includes a monitor which also nicely takes care of the lack of the latter in the Atlas rigs. If one wants to add a monitor and use a hand key, the circuit of Fig. 3 is very suitable. The circuit is actually rf powered, although this is not obvious since pin 8, via the 10k pot, is actually connected to an rf rectified voltage point of the swr bridge built into the transceiver for swr protection of the output stages. Both volume and tone of the CW monitor are adjustable. These controls can be PC board types, adjusted once and left alone, or they can be brought out as back panel controls.

Finally, for enjoyable CW, one does have to add more selectivity. Abundant active audio filters have been described to suit the purpose and so this point won't be belabored. Fig. 4 shows one very suitable low cost active audio filter which peaks about 750 Hz. It can be connected in the Atlas audio chain by breaking the leads before the af gain control or used as a separate circuit only when headphones are plugged in. There are enough contact possibilities on the headphone jack to arrange this. Used this way, the problem of providing an in/out switch for the peaking filter is avoided. As with almost any active audio filter, the key to obtaining the best performance from it is not to overload it. Driving it too hard will considerably broaden its selectivity peak and produce a "mushy" output.

Those using Atlas rigs with some of the earlier Atlas ac power supplies have noted a disturbing dimming of the panel lamps during modulation. Atlas has produced a power supply modification which takes care of this problem. Fig. 5 highlights the modifications necessary to improve the power supply regulation so no dimming is apparent. The diagram also shows the complete power supply diagram, in case one wishes to try to duplicate the circuit. A neat construction procedure is used in case of the 1N3491R diodes which form the full wave rectifier for the "high amp" (transmitter) power supply line. These diodes have their anode as a screw stud so they can be bolted *directly* to the chassis of the power supply to form a heat sink for the diodes. The simple 1N4005 diodes handle only the approximate 500 mA load of the transceiver when in the receive mode and require no special care. ■

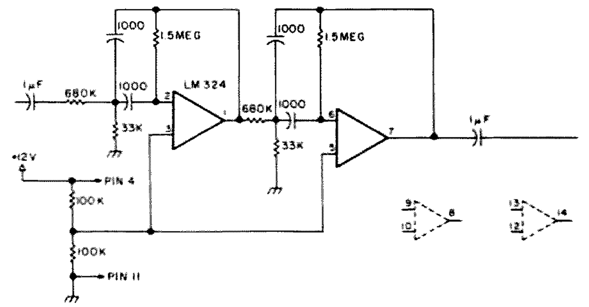

Fig. 4. Audio peaking filter for CW to be installed before the AF gain control or in the headphone lead. Note the two stages are the same. The IC contains two unused amplifiers (dotted lines) and these can be used also for a somewhat sharper filter. The 1 mF coupling capacitors are needed only for in/out coupling, not between the stages.

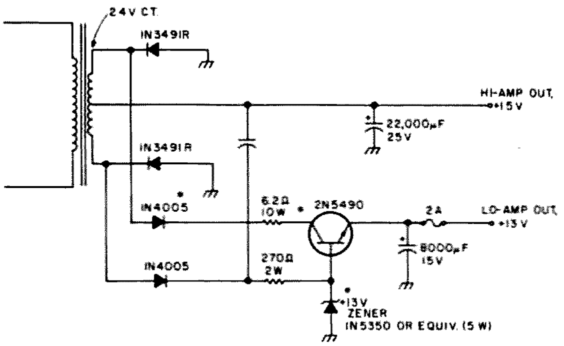

Fig. 5. Diagram of the Atlas ac power supply. The three components marked with an asterisk can be added to earlier model power supplies to improve regulation and eliminate dial lamp blinking during modulation. Home brewers can duplicate the supply if a good 24 volt center-tapped transformer can be found that will deliver 8-10 Amperes continuously.

PC Layout Tips

- - next time, do it right !

Many easy methods for printed circuit board fabrication have been published before, but most of them are limited in that only simple boards can be produced with them. In these days of IC keyers, IC frequency counters, etc., this is rather undesirable.

I recently ran up against this problem when building the K2BLA keyer (*73 Magazine*, December, 1973). Not possessing a drill press or the fancy photographic equipment that seemed to be necessary for construction of a PC board accommodating ICs, I came up with another method using neither. It will produce a PC board with a minimum of effort.

Assuming that no circuit board plan or template is available, one can be made in the following manner: Lay a sheet of paper on a flat piece of styrofoam or similar material. Now, using actual components, stick them into the styrofoam as they will appear on the finished circuit board and draw connecting lines and pads on the paper. Because of the nature of the styrofoam, components can be shifted and rearranged until a pleasing template is obtained. Here are a few general hints that should help when doing this:

1. Remember that circuit diagrams don't always show Vcc and ground connections for ICs; these must be included on the board for the device to function.
2. Try to bring all outside connections to one side of the board – this looks neater and is easier to work with.
3. A list of interconnections between ICs often helps to place these parts.

Once the circuit board template is finished, remember that it was made for the component side of the board and is the reverse of the foil side. To get the foil side template, first lay a sheet of paper on a piece of face-up carbon paper. Now lay the completed circuit board template on top of the sheet of paper and trace over the template with a pencil or blunt instrument. The reverse of the template will be transferred to the sheet of paper.

Now locate the points on the board where ICs will be located. Find a pattern that corresponds to the case style of one of the ICs. Remove it from the page (or better yet, make a copy of the page) and tape it by the edges to the place where the IC will be positioned. Now take an awl or a similar tool and position it on one of the small black dots on the pattern. Tap gently on the awl with a hammer or just press down on it until an indentation in the foil is made. Repeat this for each pad on the pattern and then remove the pattern and drill through each indentation with a small drill bit. A #60 bit is good for this purpose.

When the above procedure has been followed for each IC, draw pads around each of the holes – a resist-ink pen will work well. Then draw the rest of the circuit on the board (or use paint, tape, or another suitable resist). Let it dry, and then etch the board.

When etching, try to keep the etchant warm or even hot. This will speed the process a great deal and can be accomplished with a double boiler arrangement (with hot water surrounding the container where the board is etched). Another way to speed etching is to continuously agitate the container.

Now get that keyer – or whatever – on the air! ■

Radio Equipment Insurance

- - foil the Hamburglar

Proper insurance on your ham equipment can prevent painful headaches when you have a loss. Proceeds paid out on the loss of ham gear often do not represent actual replacement cost of the equipment.

As a property and casualty agent for an insurance company, I've learned a considerable amount about "proper coverage."

Until recently, most insurance companies have included losses of this type under the comprehensive portion of your auto policy. Due to tremendous losses of CB radios (mostly by theft) reported nationwide, nearly all companies are now excluding two-way communications equipment from this coverage. This is now an optional coverage which can be purchased for an additional premium on your auto policy. And this coverage applies only to equipment which is permanently installed in your vehicle. The rates will vary from state to state, but I've seen $10 per year to $500 per year, depending on the state and the company and the equipment insured.

Most homeowner's, renter's, and mobile homeowner's policies include coverage for ham gear under the personal property section of the policy. This coverage is in force when the gear is located at the insured's permanent home and can be extended, on a limited scale, to cover other locations.

Both the coverage under the auto policy and that afforded under the homeowner's, renter's, and mobile homeowner's policies are good.

But disappointment, disgust, or anger may result when you have a loss to a hamburglar or fire. Depreciation is a factor which all insurance companies use in determining loss to personal property, and this includes ham gear. In the eyes of an insurer, you have possession and use of that gear for one, two, five, or even ten years. So, when arriving at a settlement figure — the check the insurer writes you — dollars of value will be taken off the actual replacement cost of that gear. Depreciation is coupled with any deductibles which almost always apply, and the final settlement may be very disappointing as well as costly for you.

The best way to save grief is to insure your gear on an Inland Marine Floater Policy. This floater is usually attached to the homeowner's, renter's, or mobile homeowner's policy. The premium is not prohibitive, either. Again, depending on your state and your company, premiums per $100 of value may vary from as low as 25 cents per $100 of value to $2 or more.

The biggest advantages of insuring your gear on a floater are that the coverage literally floats with the equipment and depreciation is usually not a factor. As a result, the amount you are paid at loss time has already been determined. This agreed-upon amount is stated right in the policy. And the deductible clause is usually low or non-existent.

Before you run down to your local insurance agent, you should have some facts and figures to present to him. First, write down the make, model, and serial number of each piece of gear to be insured. A brief description of each piece will be required. And, of course, the fair replacement cost of each item must be included. Cancelled checks, bills of sale, or other proof of purchase and/or value will be helpful too. Finally, your agent may require photographs of the equipment to be insured. Even if he doesn't need photos, it's a good idea for you to snap photos of your equipment and file them with your policy and the list of serial numbers. These pictures need not be any more than a sharp Polaroid. Visual identity of the items is the key here.

This may seem like a lot of effort and trouble just to get insurance. But I'll guarantee you that the effort is worth it. You see, all this compilation of info, pictures, values and all has been determined ahead of time — before the loss. And the agreed-upon amounts are what you'll be paid.

With the floater policy, you have protection wherever you may haul that prized gear. It's covered at the ham shack. It's covered while installed in your vehicle. And if you haul it to a hamfest or to a vacation spot, your gear is protected.

And when you have that loss, there is no hassle about depreciation, deductibles, or any of the usual problems involved in handling this claim under standard insurance policies. For the few extra bucks you pay in premium for the floater, you can save on headache and nerve pills when the hamburglar or fire strikes your QTH. ■

Information Management System

-- organize those articles!

Electronic hobbyists have more information available to them today than ever before: reference books, catalogues, manufacturers' data sheets, magazine articles. And the range of information is wide: stereo, ham radio, computer, CB, SWL, radio control. Even if you're into only one of these electronic hobby fields (and how many of us have only *one* interest?), keeping up with the information you need to stay current can be difficult. Unless you have a photographic memory you can't keep all this information in your head, so how do you get the most out of what you read, and how do you find this information later when you need it? I've developed a technique which may not be foolproof, but for me it is far ahead of what's in second place.

How often have you remembered a magazine article or advertisement, wishing you could recall some pertinent data from it? You can remember the magazine, perhaps even which side of the page it's on, but repeatedly leafing through its pages doesn't turn up the information. The first part of my retrieval technique handles this problem nicely.

Whenever you pick up a magazine or catalogue, be sure you have with you a "Highlighter" or "Vu-Thru" pen. These wide-tipped felt markers use a clear ink and allow you to augment a sentence or word with a colored stripe. I like yellow, but they come in a variety of colors, including blue and pink. They usually cost less than four bits.

Most of the technical publications I read get several readings, each with increasing attention to detail. The first time I'm looking for articles I want to read closely later, advertisements for new products, prices, formulas, or anything unusual or interesting. These items get a liberal swipe with the highlighter pen. This ink rarely bleeds through magazine pages and in no way hurts the future readability of the ads or articles. Highlighting just makes important information easier to retrieve — it'll leap off the page at you.

You'll also need a fine-tipped ball-point or felt-tipped pen to take notes in the margins. Have an idea on how to use an advertised product or how to customize a construction article for yourself? Jot down enough information so you'll know what you meant when you see the note again. Wayne Green talks about how *73* readers can make money with their ideas by telling others, so when you think of a way to make a construction project better, write down a few ideas in the magazine margin. You can develop the idea more fully later with no danger of losing your train of thought. Good ideas sometimes flash and are gone, never to be retrieved.

By the second time you read the publication, you have a new use for the fountain pen. Always check out the "Error" or "Feedback" or "Corrections" sections of the magazine and go back — right then — to write in the correction in the previous issue. It is important to do this even with articles you haven't read or don't see any immediate need for. The surest way to need the information you have available is to let it slip through your fingers. Remember that oddball capacitor you'd saved for ten years hoping to find a use for? When did you need it, finally? Why, as soon as you decided it was cluttering up your junk box and threw it away. Usually a need for the discarded item develops within 48 hours of its departure. Technical information is the same way. Keep everything as up-to-date as possible and you increase the reference value of each of your publications.

I know it is very popular these days to downgrade the value of advertising, to be distrustful of advertisers. What a narrow view. Especially in the technical fields, you usually find out as much or more about a manufacturer's product from his ad as you could from talking face-to-face with a sales person. You learn when new products are introduced, "bigger and better" than the old model; you learn how products from different manufacturers stack up with each other (assuming the advertising is honest — and most of it is); you discover a great deal about product utilization — how to put a given product to work filling your particular needs. And there are ways to gather even more information from the manufacturer, and ways to put the information you have to better use.

Again the old yellow pen comes in handy. Highlight pertinent information such as price, specifications which make a given product unique or uniquely applicable to your needs or addresses of local suppliers. Use your fountain pen for notes in the ads, too. Suppose you're looking for a new 4K memory board for your hobby computer. Everybody is offering a 4K memory board, so to help you compare specs write yourself notes alongside the ads, something like: "See page 116. 4K for $10 less."

The manufacturers themselves want to help us learn as much about their products as possible, yet many of us rarely make full use of the information services available. Most technical magazines, for example, have a reader service card bound into the back of the publication — you know, the card with all the numbers on it? Though I don't have firm figures, I imagine this service costs both the publisher and the advertiser a great deal of money. But it costs even more if we don't use it. As you peruse a magazine and see an interesting product advertised, flip to the back and circle the appropriate number. Don't send in the card until you're sure you've circled all the numbers you want, because most publishers won't process more than one card from

each reader. Even if they did, that would increase the cost of getting the information to you. We can help in a small way to keep down product cost by trying not to tax the resources of the advertisers. Don't send in for information you don't really need, and do use your highlight pen to indicate which advertisers you've asked for data so you won't mistakenly request the same information twice. This could happen if he promoted a different product in next month's issue or had a different ad in another publication. Usually if you circle a number from an ad for a 4K memory board, for example, the advertiser will send you his general catalogue or whatever he has available, in addition to the information you specifically requested. There's no need to send in multiple requests to the same company.

You'll find, too, that most manufacturers are quite helpful in answering specific queries. Write a to-the-point letter explaining where you learned about the product — why you need more information. Then list your questions one at a time and leave adequate space for the company reply. You get quick service this way, you have a record of your questions and the company's reply, and you've saved someone the trouble of writing a personal letter. While not as formal, this technique ultimately provides you and others better service by saving the advertiser or manufacturer time, and since time is money . . . well, you get the idea. You may find that enclosing an SASE with your letter will speed up the reply from some companies.

Now you've got all this information carefully marked and annotated, and your mail box is filling up day by day. What are you going to do with this flood of stuff? An inexpensive filing cabinet and a stack of manila folders are what you need. If you don't already have an office of sorts set up in your ham shack or computer room, you ought to start one. Pick up a cheap cardboard, two drawer filing cabinet from Sears or your local discount store. I paid $5.95 for mine a few years ago. They are lightweight but strong, and will last for years (Sears' latest catalogue lists a two drawer steel cabinet for $19.95, if you want more permanence). One two drawer cabinet probably will last the average hobbyist a long time if he's just using it to store technical information.

Use whatever system is helpful to you, but arrange the information according to subject so you can find it later. I have folders labeled variously: "Clock circuits," "Computers, general," "Memory boards," "Specialty catalogues," "IC data sheets," "Antennas," "Receivers," "Transmitters," "Hi-Fi, stereo, general," etc. Now when you get somebody's poop sheet, give it the highlighter and fountain pen treatment (perhaps cross-referencing the data to the original ad or article that prompted your interest). Then stick it away in the appropriate folder. I usually keep a sheet of notebook paper in the folder, with subjects on it that I reference most frequently. If I learn a useful tidbit of information (a formula, a source for equipment, a building technique), I jot it down on my sheet. I don't have to remember where I saw it when I need it again; I just go to the appropriate folder and look at the latest entries on my hand-written data sheet.

Treat your catalogues the same way. Arrange them on a bookshelf according to subject, highlight portions you find most interesting, cut out and save product information from catalogues you're discarding. Many companies publish IC data sheets, circuit diagrams and the like with their catalogues. This information can be invaluable when filed so you can retrieve it — and it's free. Too, mark the date you received each catalogue near the address label. This helps you decide which catalogues are out-of-date as new ones arrive.

Use a copying machine. Many people have access to a copier at work, or you can find one at the local post office, library or other business establishment. My bank offers a copying service, giving very good quality for a modest price. Expect to pay about a nickel a page for info-only quality, and about a dime a page if you really want that circuit to be as good as the original. If you make a great many personal copies on your business machine, it is only fair to make arrangements to pay for them — probably at a reduced rate. Otherwise, you're stealing from yourself and others who work with you, raising business overhead for personal gain.

By using copies of articles and ads you can file this information away with your mail-outs while keeping the magazine or catalogue intact. There are, however, some publications which you might not keep forever. I take so many magazines that I can't possibly keep all of them on file. So, regularly I go through them and tear out ads and articles I want for reference and throw the rest of the magazine away. This cuts down on the storage problem, while giving you good access to needed information. I usually wait until the year is out, however, before making the decision to rip and file.

Many publications regularly provide instructive articles in a series ("How Do You Use ICs?", in *73*, for example). If the subject is interesting and the articles are well done, why not make up the series into a booklet when it is completed? You can either rip out the originals or make copies. Staple the pages together with a stiff cardboard cover, use a commercial binder you can pick up in the school supply section of your grocery store or discount outlet, or simply put the series in a manila folder and label it. You'd be surprised how useful it can be to have the whole series together so that you can reference it like a book when you need the information. A note on copying: If you think you might want to copy something, don't highlight it first. The highlighted portion sometimes copies dark and is hard to read. So copy the material first and highlight it as you re-read. Of course, you can make your margin notes before copying if you don't use a red pen. Most copiers don't do a very good job of copying red ink.

Another excellent information retrieval aid is the year-end listing of articles provided by many magazines like *73*. Usually published in the last issue of the year, these listings are well cross-referenced and are a great help in finding just what you need for that next project. Again, I find a copy machine helpful. Copy the list, then cut it up according to subject and file the listings with the appropriate material in your filing cabinet. You may not have copied the full article the first time around, but having the cross-indexed reference on file can be almost as good. Alternately, you can hand copy the most interesting references on your notebook paper sheet in each file. If you know enough about your individual needs, you can transfer in a reasonable time all you're likely to want.

One more thing. Keep a card file, 3" x 5" or 4" x 5", depending on your needs. Have you ever spent a long time researching a subject, finally found just the right source, wrote off for the information, and then lost the address? When your query is lost in the mail or in the paper shuffle at its destination, you might have to start all over again with your original research. So keep a

file card copy of what you learned the first time and there won't be a second time.

Long distance telephoning is easy and relatively inexpensive these days, and some of us tend to use it to get technical aid with a specific product. When you have talked directly with someone at a given company, be sure to find out the name of the individual who helped and make a note of the type of information provided, the department in which the person works, the telephone number and the department extension. File away this information on two cards: one with the company name and another under the subject involved (memory boards, to continue our example).

Sound like a lot of work? For someone who isn't used to getting things organized it might, but once the ground work is laid it's easy. Once you get the system operational – i.e., when you've purchased a filing cabinet and manila folders, when you have the yellow (or blue or pink) marker in hand – then the system mostly takes care of itself. You'll likely start out simply, with large subject designations in your files. But as you get more information you'll do away with such general labels as "Computers" in favor of folders marked: "Computers, mainframes," "Computers, memory," "Computers, interface," "Computers, power supplies," and so forth.

You'll soon wonder how you built even a simple code practice oscillator without first researching available circuits from your file cabinet memory. But if you're an addicted saver and organizer like me, you'll have to learn, too, how periodically to sort through your bulging files and tearfully toss out a few sheets you haven't used in a long time – and won't need, until you see the trash man driving with them down the street. ■

CW Keycoder Improvements

-- visual space indicator

The CW Keycoder 1 authored by WA9VGS in the July, 1976 issue of *73* was excellent. However, there are a couple of modifications that I myself incorporated, and made the project very pleasing. References will be made several times to the above article.

When I went parts searching, I found that the SCR described as a 2N889 or equivalent was hard to find. In fact, in looking through some old catalogs (Deeco, Cedar Rapids IA), they indicated a price of $38.00 each. That, of course, was back in 1968. Recent prices of around $16.00 proved to me that there must be another SCR that would work without putting a dent in my billfold.

Sylvania's ECG 5404 did the trick. There are changes in the circuit, but nothing drastic. See Fig. 1.

Another problem that I encountered was the type of keyboard that I purchased at a flea market. This keyboard was built for National Cash Register by Sanders Associates, Inc. My experience was that only some of the characters would activate the SCR. This had me going for quite some time as all the switches checked out ohmically perfect. Keys that wouldn't function were like the "M" and "N", but "A", "B", "0" would work. In tearing down those that wouldn't work, I found absolutely no difference electrically or mechanically. After a few tests, I found that increasing the cathode current of the SCR helped, but other problems arose. This was not the solution. I finally realized that the particular keys which didn't work also had upper case functions. These glass enclosed reed switches had a different propagation time element. My only solution to this problem was to exchange these switches with extra keys that I wouldn't be using, such as "INSERT FORMAT," "DELETE FORMAT," "SEND BLOCK," etc. There were enough to complete the alphabet and numerals. The moral of this is to be sure of the type of keyboard that you may purchase, and know what type of switches are used.

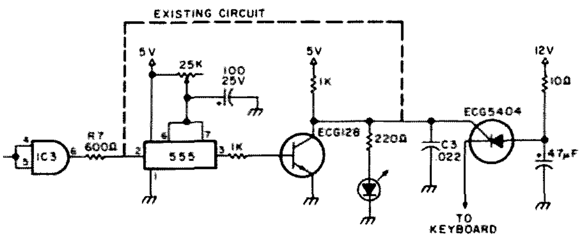

Fig. 1.

I installed the second modification after I used the Keycoder for a while. With the speed control, you are able to control the speed of characterization, but not of the spacing between the characters. Since I use the Keycoder for teaching CW in our amateur classes at our club, it was desirable to be able to send CW at precise words per minute. To meet this requirement, I installed an NE555 timer between the 600 Ohm resistor (R7) and the gate of the SCR. In Fig. 1, you will find that when a low is present on the output of the gate IC3 pin 6, during characterization, this causes a low on the input of the timer pin 2. This starts the timer into operation and a high is then present on the output of the timer. This high turns the inverter transistor on (saturated) and, in turn, the collector voltage drops to zero. This low is applied to the gate of the SCR, which disables the keyboard. With the space adjust pot adjusted properly, the keyboard will not function until the timer has reset. Even when the high is returned to the input of the timer, after characterization, the timer has to reset before a low is presented to the base of the transistor. When this occurs, the collector voltage will go up to the power supply voltage and ready the gate of the SCR. An LED was installed in the collector circuit so a visual indication would be given as to when the keyboard was ready. When the LED is turned on, it means that the keyboard is ready for characterization.

As you can see, this enables one to be able to control the spacing of his characters visually. A calibrated dial can be placed around the space control to indicate the wpm.

Another change that I made to the Keycoder which I feel was worth the time was to install a phono jack on the panel for external keying with a telegraph key. This jack *must be insulated* from the chassis if the chassis is common to the power supply. With a 1k resistor connected between plus 5 volts and the center pin of the jack, and the outer pin connected to pin 4 of IC2 (555), this will permit keying of the sidetone generator and also the relay. With this, we are able to use this keyboard with versatility, especially when we have Novices learning to send CW. It's a beautiful instructor's aid.

I wish to thank WA9VGS for the very fine article and *73* for publishing it. I would like to also thank Hobby Industry in Council Bluffs, Iowa, for their fast parts procurement of the Amidon cores used in this project. ■

Heath HW-2021 Review

-- a lot of HT for the price

Photos by Jim Gerritz WA4FMA.

When the Heath 2 meter FM HT appeared on the scene, I was in the market for an HT. Many things about the Heath interested me, not the least of which was the price. One hundred seventy dollars ($170) for a 5 channel receive, 10 channel transmit, 1 Watt HT with "rubber duckie," nicad pack and charger seemed like quite a deal – so I ordered one.

My kit arrived and I was really impressed (and a little intimidated) by the piece of Swiss cheese referred to as a circuit board. After checking the parts, I started on construction. Two things became immediately obvious: First, Heath's warning about this kit being "for the experienced kit builder" is very true. It is very easy to make a mistake and constant checking of component installation is a necessity. Second, they make a little remark about taking "a short break after completing each half or full section" of the board. The board is a double-clad glass board with plated-through holes. The side of the board where the soldering is done is coated with some goop which is supposed to, and does, keep solder from flowing where it doesn't belong.

The board is marked into six sections. Almost all of the circuitry is on this one board. I found that one section a night was all I could handle without having a fatigue problem. I would recommend that those of us whose arms get a little shorter each year invest in one of those circular fluorescent lamps with a magnifying glass in the middle.

I had the charger, battery board, and four of the six sections done when it came to my attention that all was not as it should have been. A little investigation and a phone call to Heath showed me my problem. I had an early model with a 00 series number. A little word on the Heath series numbers. These are NOT serial numbers, but identify when the kit was manufactured. The series number is a five digit number, the first two digits of which indicate the revision number. Hence, a series number starting with 00 is an original issue. The third digit is the year of manufacture and the last two digits, the week of that year. The HW-2021 I have *now* is series number 01607 which means it is the first revision, manufactured in the seventh week of 1976.

Well, back at the workbench, Heath offered to send me all the changes in parts and instructions to make my kit up-to-date, but I was a little "gun-shy" and asked for a whole new kit, which they promptly shipped upon return of my partially built kit. The new kit had several circuit and part changes, a whole new instruction book, and three pages of changes to the new instruction book. The early kits had problems with the battery saver circuit, the diode antenna switching, and a lack of drive in the transmitter. There were also problems in the instruction manual. However, the 01 series kit corrected all these problems and my kit was assembled and aligned by the book with no problems. There were a few shortages in the parts list, but these were promptly supplied by Heath.

Circuit Description

Referring to the block diagram, you can see that the receiver is a rather conventional single conversion receiver. Diode switching is used in the antenna circuit (look Ma, no relays or multipole PTT switches). The rf amp consists of two 40673 dual gate MOFETs in common source configurations. A third 40673 is used as a mixer. Two monolithic crystal filters are used at the 10.7 MHz i-f to give a 4 pole filter response. A single bipolar transistor and an RCA CA3089 IC is used as the entire i-f chain and detector. A rather novel circuit innovation is the use of a 10.7 MHz crystal to raise the Q of the quadrature detector. The audio amp is a Motorola MC1454 IC.

The oscillator chain consists of a 15 MHz crystal

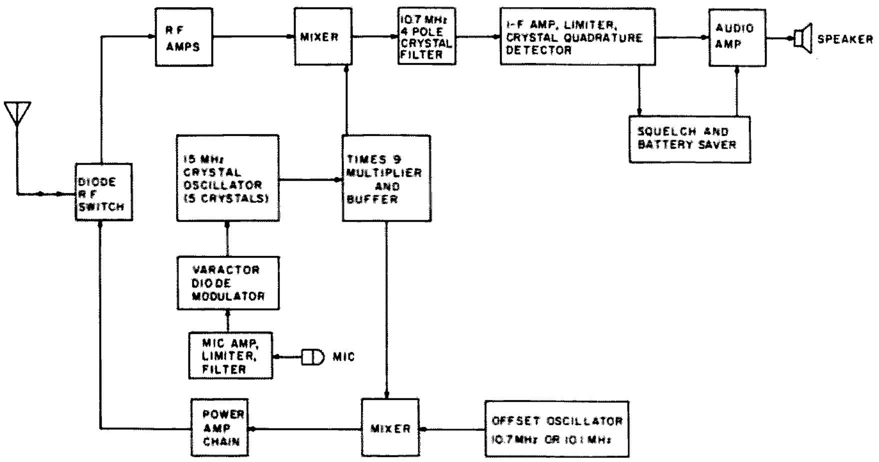

Fig. 1. HW-2021 block diagram.

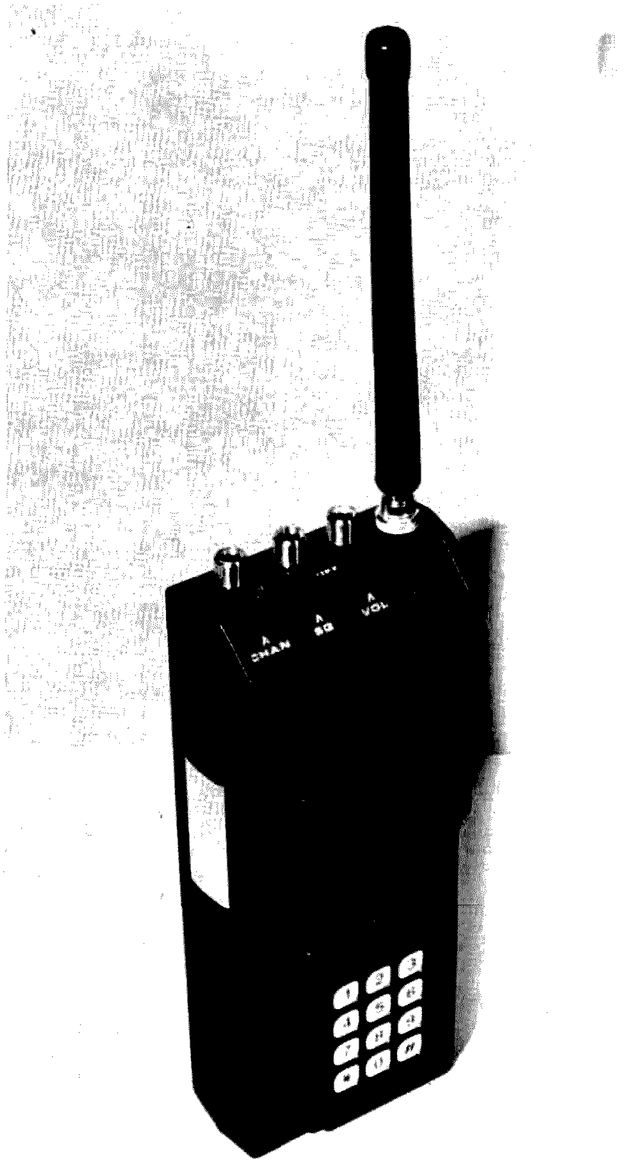
oscillator followed by two triplers and a buffer. There are five diode selected crystal positions, each with its own netting capacitor. The output of the chain is 10.7 MHz below the receive frequency. The squelch and battery saver circuit is one of the unique features of this HT. As long as the receiver is squelched, there is an oscillator that runs at about 3 Hz. The output of this oscillator turns on the entire receiver for about 20 ms three times a second except for the crystal oscillator, which runs continuously. So for 313 ms out of every 333 ms, the load on the nicad pack is just the crystal oscillator plus a small load in the battery saver circuit itself. The audio amp is not controlled by the battery saver but by the squelch, and when squelched, the load is small. All this adds up to a minimal load on the nicad pack when no signal is being received.

When a signal is received (during one of those 20 ms receiver on periods), the squelch is opened, the 3 Hz oscillator disabled, and the battery saver turns on the entire receiver as long as the squelch is open. The audio amp is also enabled. The signal goes away and the battery saver resumes operation. All in all, a rather cute circuit. (Hmmm – a squelch operated 3 Hz clock oscillator and diode switched crystals. Sounds like half a scanner!) There is an LED on the front panel that flashes when the battery saver is in operation and is on solid when the squelch is open. The squelch itself is a signal amplitude operated circuit rather than the more conventional noise operated squelch.

The transmitter is less conventional. The same crystal and oscillator chain is used as is used by the receiver. There is an offset oscillator with 10.7 MHz and 10.1 MHz crystals supplied with the kit. The output of the main oscillator chain and the offset oscillator are mixed in another 40673 dual gate MOSFET to give the transmit frequency. The mixer is followed by five bipolar transistors to bring the output power up to the proper level. Note that one crystal will give one receive and two transmit channels and, once one of the transmit channels is trimmed on frequency, the receiver and the other transmit frequency are on frequency within 250 Hz. Purists could probably trim the offset crystals, but I really don't think it is necessary. With my unit there is about a 130 Hz error on one transmit frequency if the other is set on exactly. As an example, the crystal supplied with the kit is 15.1377 MHz, which gives 136.24 MHz (when multiplied by 9), the proper injection frequency for a receiver with a 10.7 MHz i-f, for 146.94 MHz. Mixing the 136.24 MHz with 10.7 gives 146.94 MHz, and with 10.1 MHz gives 146.34 MHz. So you get simplex and the -600 kHz offset for 146.94 MHz with just one crystal. Modulation is accomplished by a varactor diode across the 15 MHz crystal, driven by a mike amp, limiter, and filter consisting of a JFET and a 741 op amp. The HT has a separate microphone for the transmitter, reducing the switching requirements and giving better fidelity than if the speaker had been used as a mike.

The nicad pack consists of 10 AA size, 1.2 volt, 450 mAh cells in series with a simple but effective charger. The only charger circuitry external to the HT is the transformer.

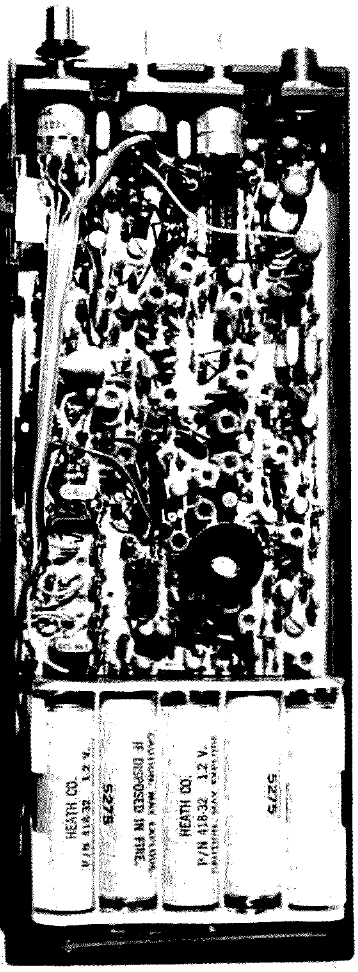
PTT is accomplished by the simple expedient of switching the nicad pack from the receiver circuit to the transmitter circuit. This is done with an SPDT microswitch under a large aluminum bar on the left side of the unit. The rubber duckie is mounted on the top right of the HT in a threaded 5/16 bushing. On the right side of the unit at the top is a standard miniature closed circuit phone jack that is used for external antenna connection. Channel selector, squelch, and volume/power controls are on top. The simplex/offset switch is on the left side of the unit above the PTT bar. The speaker is centered in the grill on the front and the mike is under the top left-hand corner of the grill. The case itself is high quality plastic, sprayed on the inside with a conductive coating. The board is mounted to the case back and the case halves fastened together using threaded inserts and machine screws. No self-tapping screws are used.



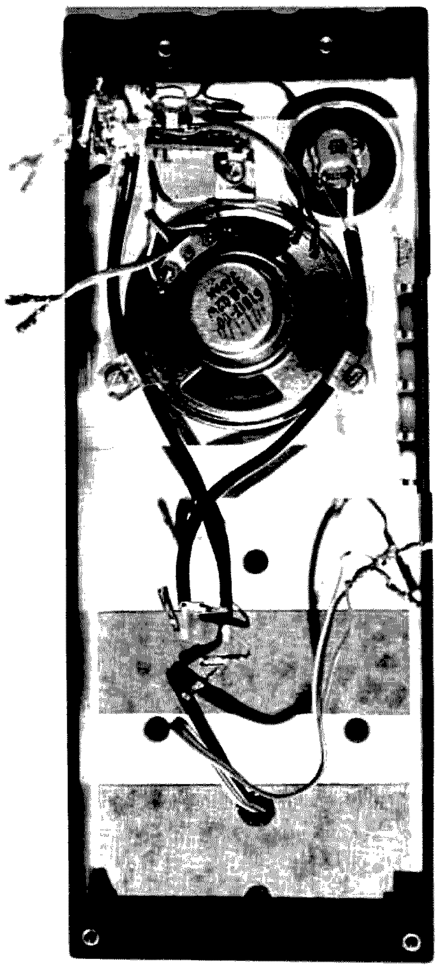
Heath HW-2021 2 meter handie-talkie with HWA-2021-3 autopatch encoder installed. Small slide switch above PTT bar on left side is the simplex/-600 kHz offset switch.

Alignment

Alignment is simple and straightforward. An rf detector and a 51 Ohm dummy load are supplied with the kit. The only test equipment needed is a VOM. The only time exotic equipment should be used is when netting the crystals, which should be done with a frequency counter, although it can be done on the air with a friend. Note: The friend can also talk to you on a repeater if direct



Inside the HW-2021. Frequency controlling crystals are on the left side about 2/3 of the way down. (146.52 crystal is in position 5. Positions 2, 3 and 4 are vacant.) Netting capacitors are just visible under the ribbon cable to the left of the crystals. The offset oscillator crystals are located between the channel switch and the squelch pot. The two crystal-looking things on the right side about 1/3 of the way from the top are the monolithic crystal filters. Note the 2-56 screw in the rubber duckie bushing at the top right — very difficult to get a screwdriver on to connect the rf cable. Transistor with heat sink is rf output.



Inside the front cover of the HW-2021. Small jack at upper left is the external antenna connection. Three wire ribbon cable coming through the bottom is from the HWA-2021-3 autopatch encoder.

is used with the HT. No problems were encountered in alignment.

Performance

The published specs on the HW-2021 are not earth-shattering: one Watt output and receiver sensitivity of 0.5 uV SINAD or 0.75 uV for 20 dB quieting. This is across a ±1 MHz range from the alignment frequency. My unit has only been used between 146.16 MHz and 146.94 MHz, but I found the performance quite a bit better. My output power was 1½ Watts across the measured range and the sensitivity measured on a Singer FM 10 CS meter was 0.25 uV for 20 dB of quieting. The squelch operated well below 0.2 uV. The receiver is quite immune to intermod and adjacent channel rejection is adequate. I can copy the 76 machine in Pensacola, 50 miles away, while the local 79 repeater is operating. It does suffer from desensitization and plain front end overload when operating in the immediate vicinity (100 meters or so) of an off-frequency source of a few Watts. The squelch circuit leaves a little to be desired. Since it is an amplitude squelch, it is more sensitive to external conditions, such as noise levels and hand capacity, than a noise squelch. The setting of the squelch is relatively critical, there being a narrow range between keeping the squelch closed and having it open with a weak but copyable signal.

The audio output is rated at ½ Watt. There is sufficient audio to hear a station in an open car (my wife's VW Thing) at 55 mph. The audio can be run all the way open without objectionable distortion.

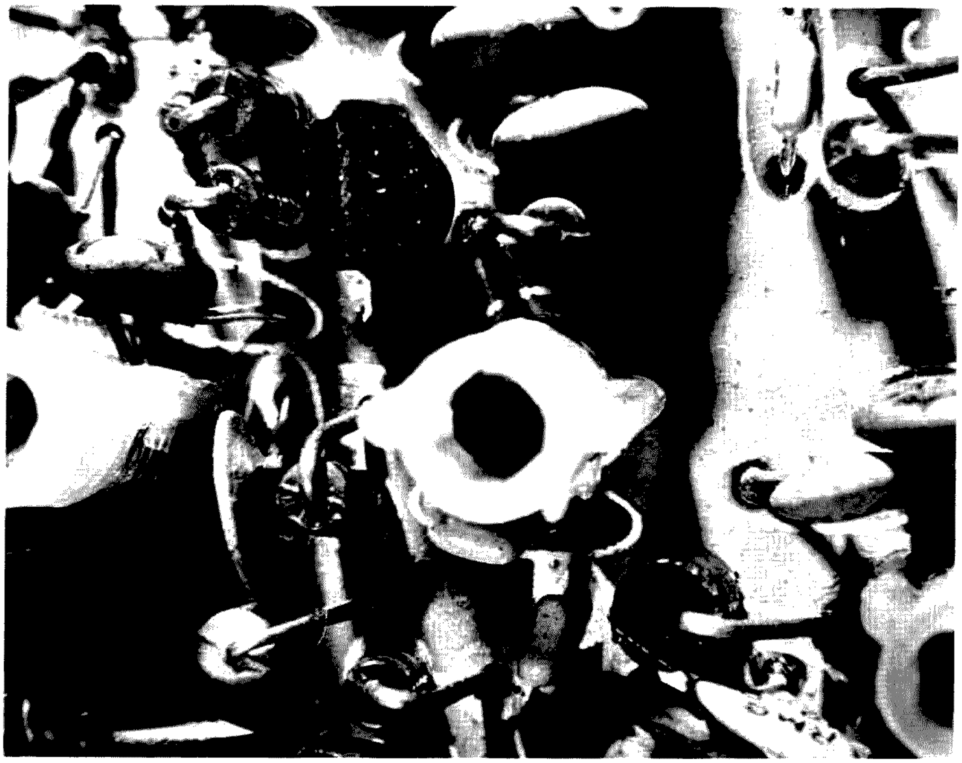
The transmitter has only two problems. The modulation is nonsymmetrical. My unit had an upward deviation of 7 kHz while downward was only 3.5 kHz. The other problem is the PTT sensitivity. It is, for me, much too light. Even with the optional installation to increase the pressure necessary to actuate the PTT, it is much too easy to activate the transmitter accidentally.

Opinions

I felt several improvements could have been made in the kit. I don't like using the phone jack for an rf connection. A BNC jack on top instead of the 5/16 threaded bushing with a BNC rubber duckie would eliminate the

phone jack for external rf connection and clean up some of the internal wiring. It would also allow the phone jack to be used as an external mike or earphone jack, neither of which are provided for. This is a change I am seriously considering for my unit. Also, there is no provision for operating from external power while protecting the nicad pack from possible excessive charging current. This means that all operation must be done off the nicad pack. The nicad pack snaps in place easily, but is not particularly easy to replace since the unit must be opened up and several leads disconnected to get to the pack.

The coax cable used for rf is not to my liking. It's the stuff that has foil instead of braid with a wire running down the foil. This shield wire is rather brittle. I would rather have seen a good high quality subminiature coax used.



Close-up of one section of the main board. Not a helluva lot of spare room. Note ferrite bead rf choke at bottom right.

With the +600 offset activity increasing above 147 MHz, a third offset position would have been nice. As it is now, I would have to sacrifice simplex or -600 offset to get the +600 offset.

There were three areas in construction of the kit that bothered me. First, whenever I cut a cable to the specified length, it seemed that when I installed it, it could have been another ¼ inch longer to make final assembly easier. Secondly, the builder is required to build up a solder bead around a mounting hole to get proper board clearance. Why not a washer? Third, a 2-56 screw is used to attach the rf line to the rubber duckie bushing. It is quite difficult to get to this screw without bending board components this way and that, and you still have to bring the screwdriver in at an angle.

Conclusion

For 170 bucks, the kit is a bargain. It went together, aligned properly, and exceeded spec. The quality is excellent, as is the manual – the kind of equipment we have come to expect from Heath. It's a little larger than most HTs (23.5 cm x 4.8 cm x 8.3 cm) but I would not have cared to build it had it been any smaller. It is sturdy, but not indestructible. I have dropped my unit three times and it broke twice. Once one of the crystal filters broke and the other time one of my crystals broke. Maybe I shouldn't have been so cheap; I should have bought the optional carrying case.

It's not perfect, but its virtues far outweigh its deficiencies and I would highly recommend it for anyone with kit building experience.

THE HWA-2021-3

After my positive conclusions on the Heath HT, I wish I could be as positive about the matching autopatch encoder – however, I can't. It's bulky, technologically obsolete, uses some rather questionable construction techniques, and does not meet the published 1½% accuracy spec. Much better pads can be obtained for the $40 the HWA-2021-3 costs.

Circuit Description

The circuitry is rather straightforward and old-fashioned. Two NE555s are used as separate high and low group oscillators. Precision (1%) resistors are switched by a miniature 12 button keyboard to generate the proper frequencies. The charging voltage waveforms across the timing capacitors are mixed in an LM301A which also filters the waveforms to make them approximate sine waves. There is also a PNP transistor driven by the square wave output of the low tone oscillator which in turn drives an LED. A rather useless circuit that lights the LED when the low group oscillator is running.

Alignment

Alignment is simple. A trimpot for each group is set at the highest tone of each group. The other tones supposedly will then be within the ±1.5% spec. The pots are mounted on the bottom of the board with the adjustment screws *facing each*

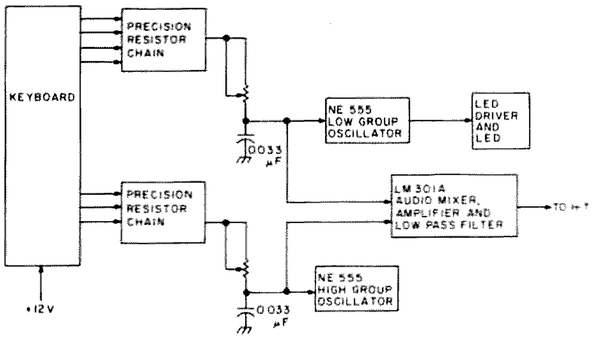


Fig. 2. HWA-2021-3 block diagram.

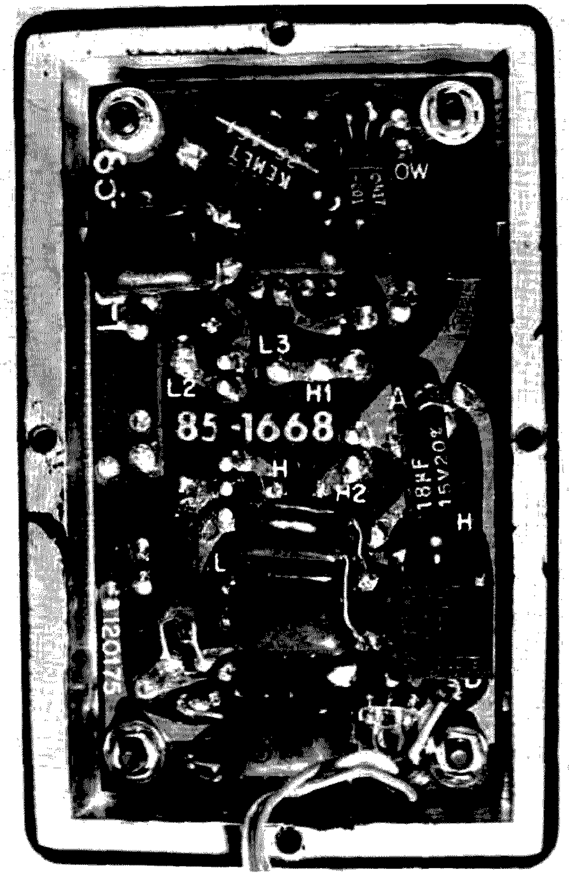

Rear shot of HWA-2021-3 demonstrates most of its faults. The two tubular 18 uF capacitors, one at the top and one at the right, are tack soldered in place. The ridiculous arrangement of the tone alignment trimpots at the right is obvious. The .01/.02 parallel capacitors necessary to make the whole unit work within spec are located at the top left and bottom center. The transistor at the top right drives the useless LED. Small pot at bottom right sets the output level.

other! Very difficult to adjust and impossible with the pad mounted on the HT. Had they turned the pots 90° and drilled holes in the side of the case, alignment would have been much easier.

Performance

To make a long story short, it didn't meet the 1.5% spec by quite a bit. It was close enough for the phone company as long as the low tone of each group wasn't used. That eliminated 1, 2, 3, 4, 7, and *. The tone decoder on the local repeater is more critical than the phone company and since the 1 and * are used in the autopatch access sequence, I might as well have not had the pad. I tried aligning in the middle of the ranges and ended up with both the high and low tones of each group out of tolerance. I checked and rechecked the circuit and had friends recheck it and could find no assembly error. I checked the resistor chain with a Fluke 8125A digital multimeter and they were within tolerance. I tried several different 555s and .033 timing capacitors and the results were always the same. I then decided to check the design. Running the circuit values backwards through the design equations, I found that the pad was operating as expected given the components supplied with the kit. Well, I had $40 into this thing, and wanted to make it work. My options were either to change the precision resistor chains or the timing capacitors. I worked under the assumption that the resistor chains were correct (two mylar capacitors are cheaper than 7 precision resistors), and resolved the equations for new timing capacitors. Both capacitors computed out to 0.03 within 1%. I couldn't find any 0.03s, but 0.01s, and 0.02s were plentiful. So I paralleled a 0.01 and an 0.02 and substituted the pair for the 0.033s in each of the oscillators. A quick alignment by the instruction book and everything worked as advertised. Even our supercritical autopatch access decoder on WR4ABZ accepted it. I have communicated with Heath and sent them all of my lab results as well as all of my calculations. My latest correspondence from Heath reads in part: "... the chief engineer assured me that as soon as time permits, he will rerun your calculations and reply to you directly. He has also assured me that if the .03 capacitor works in your case, he sees nothing wrong with installing it ..." That letter was dated 24 June 1976.

Opinions

My pad is in use with the .03 capacitors and works well. The parts are of good quality and the manual is excellent. The board is double-clad glass with plated-through holes. However, there are two filter capacitors which are tack soldered on the back side of the board, a practice I consider poor. I have already mentioned the absurd mounting arrangement of the alignment pots and the useless LED circuit.

Conclusion

For 40 bucks, forget it! You can get a smaller, better pad cheaper. ■

The First Step

-- mystery and adventure

My boss once had a plaque on his wall which read, "To hell with finding a solution, let's fix the blame." Last night, while sitting in my own private Valhalla of wires, lights, and humming equipment, far from all but the most piercing of screams from the kids, I found my thoughts weaving backward looking for my initial step into ham radio.

I can't blame my brother for this one. He had been interested in radio a few years before, but I never cared a rap for what he liked. On the other hand, it was through him that I joined the Bunker Hill Boys Club, and that institution must take most of the blame.

If you're the kind who likes solitude, stay away from a boys club. Every major city has one or more of those diabolical institutions, complete with wall to wall kids of every shape, size, and color, and even the executive office isn't immune to visits from the diminutive membership, especially when a fight has to be settled.

Now we're getting closer to the center of the problem. I mean when we mention a fight. Sure, I'd joined the radio group at the club, but after fidgeting for a while with the code practice oscillator and watching the pattern on the screen of an old oscillograph, I'd gotten my fill of electronics – or so I thought. That was when Bob entered the picture.

Bob and I were natural for thoughts of mutual homicide. We were pretty close to the same age and on opposite sides of the nation's oldest high school rivalry. Now, giving him the benefit of the doubt (in addition to the concession of not revealing his first name which he no longer uses in public), I will say, in all fairness, that I really don't know who started it, nor did I know at the time, nor did he, but fight we did, as kids will often do, and it was a lulu.

We invited each other to step outside into the hallway, and had at it for an hour or more while Jim (he was in charge of the radio room and was the only adult to figure into all this nonsense) remained discreetly on the other side of the door. Bob was a much better scrapper than I, but I was too stupid to give in. We had at it till we both were exhausted, called a truce to rest (during which period Bob offered some constructive criticism to my lousy pugilistic techniques), and then had at it again. Bob's pointers were helpful, but not helpful enough. I still got the worst of it.

The other members of the radio group had long since gone home, and Jim, tired of sitting there by himself, called us in to cool off. I sat wearily down on one end of the bench by the code practice table, feeling very sorry for myself and hoping the world would share the sentiment. Bob, feeling brisk after his pleasant exercise, chatted for a while with Jim and then switched on the old Hallicrafters HT-9 transmitter and started calling CQ.

As I watched that very despicable person, at that moment the world's meanest bully, operating the radio station by himself, I could feel the hairs on the back of my neck bristle with resentment. I hadn't even known there was a transmitting station in that room, let alone that there was anybody able to operate one. I had heard of radio amateurs. My brother (who never exaggerated or told a lie) had said you needed a license to use one of those things. And to get that license you had to know Morse code (at least 750 words per minute) and take an exam consisting of eight million questions made up by Dr. Einstein, while the FCC examiner stood behind you with a bullwhip waiting for you to make just one little mistake. Surely such a thing was out of the question for me. Yet here was that terrible, horrible, rotten, no good, very bad person, and he'd made it.

I don't know of anybody in the amateur radio hobby that began without the assistance of another ham. But, however much help is offered from another, there is a moment when an individual has to act on his own if the thing is ever to happen. When that moment comes you often don't realize it or ponder on the possible far-reaching consequences. When I turned around in my seat, donned a pair of headphones and picked the card containing Group I of radiotelegraph code characters, I took the first halting step on a road that hasn't come to an end after 25 years. There was no thought of a license – just blind rage and a reckless vow to match anything that guy could do or die trying.

Strangely enough, the enemy proved to be a friend, although I didn't really appreciate it at the time. Half helping, half mocking, Bob kept me mad enough to keep at it. He would sit down at the key, betting that I couldn't copy whatever insult he could think to translate into dots and dashes. For the time, Jim kept an eye on the progress, but otherwise stayed out of it. Once in a while he would sit down at the key himself and give me some real practice.

The more I stuck with it, the more Bob seemed ready to encourage. Bit by bit the resentment died away to be replaced by a growing friendship. (Besides, I had reached the conclusion that, as a friend, this guy would be far less hazardous to the health.) Jim entered the scene more and more until I had the code pretty well memorized. Then he saw to it that practice continued every time I showed up. I don't know how many hours I spent there with the phones on, copying code through the din and racket that is a way of life in a boys club. But one day, out of a clear blue sky, Jim casually asked me, "When're you going up for your ticket, Willie?"

That was the first time anybody had even so much as implied that such a thing could so much as be within reach. I pondered for a moment on my brother's sadistic description of the exam, then answered, "I dunno, maybe some day if I ever get good enough at the code . . . "

"What the hell are you talking about? You only have to copy five words a minute, and you're doing better than that now!"

Well, now, this put things into an entirely different light. I pondered on Jim's remark for a while, and then timidly asked about the written exam. That, according to Jim, was nowhere near the torture session I thought it was. In fact, Jim (who by then had had a fair amount of time to estimate my learning ability) felt I could be ready for the exam in a month or so. That did it. I strode over to the calendar, pointed to a date now long since forgotten, and announced that that was when I'd go up for a ticket. I left that night feeling ten feet tall.

Back in 1951, the Novice class license was comparatively new. You had to take the exam at the FCC office. Nowadays, you can take it by mail. It was good for only a year, and after that you had to have a higher grade license or forget it.

Well, I began cramming. Jim had one of the boys in the typing class type out a copy of the questions and answers from the club's only copy of the license manual, and I was on my way. Bob, in his half-friendly, half-antagonistic way, kept prodding me on the questions until I had the answers memorized verbatim. Most of the members of the group would leave by 8:30 or so, and then Bob, Jim, and I would remain until the club was ready to close at 9:30. Sometimes we'd chat about the various operating techniques and the ins and outs of ham radio in general. Sometimes, and it was bending the rules just slightly, Jim would let me try calling an occasional CQ, which occasionally was gratified with a QSO. All in all, W1MOS (the boys club station callsign) got quite a workout.

The big day finally came. I went, completely solo, to the Customs House in Boston, feeling very adventuresome, and requested a Novice exam. The application in those days was four pages long, and it had to be notarized. Luckily, I had some change in my pocket, and the notary in a nearby bank only charged fifty cents for his service. The test itself was uneventful. Jim and Bob had done their work well. The examiner quietly announced that I'd passed and would have a license in about eight weeks.

Now, getting a license is one thing; getting on the air is quite another. This is especially so when you're fifteen years old, live in an apartment house in the inner city, and your parents are struggling to recover from financial disaster. In Massachusetts nobody will hire a kid under sixteen, and you can't earn enough money to outfit an amateur radio station delivering newspapers. However, the club was there, and I got enough operating satisfaction operating W1MOS.

Then came the end of an era. We moved from the Charlestown area, which we had universally despised, to another neighborhood considerably removed from the boys club. I was then wholly on my own to either sink or swim. Now, there was no way in sight to buy a rig, so my only alternative was to build one. Somewhere along the way I'd formed the notion that a radio amateur had to be able to build all his equipment, if necessary, without following some one else's circuit.

The public library now became my retreat. I must have read every elementary book on radio communication they had from cover to cover. I had accumulated a few junk parts and with these began experimenting. An old wood base with a tube socket mounted on it became my classroom, as circuit after circuit was tried out with no direction, rhyme or reason behind my experiments. We moved a second time and, wonder of wonders, there was an old radio in the attic with a shortwave band on it. It had no CW oscillator, but a nearby U.S. Navy station was on the air every night sending out code groups at about fifteen words a minute.

Well, after an unbelievably long time, and after two tries, I finally had my General class license, but no operating station. The attic was a saving grace here because I had a place to tinker. Jim was still available. We had countless conversations by telephone, no question being too much for him to answer. I built a receiver, and began exploring the shortwave bands myself.

That receiver, incidentally, was a sight to behold. It was built in an old wood box that the attic had coughed up, with a type 27 tube in the detector stage, a 957 acorn tube amplifier, and a 6F6 output stage. It was enough to make any engineer vomit, but I'd built it, and it worked.

For a transmitter I hatched up a two tube oscillator with a home brew power supply, which gave out an unknown number of Watts. Our yard was just big enough to squeeze in a quarter wavelength of wire (with the consent of a neighbor who let me anchor one end on his roof). I fed it with a length of twisted pair and a series tuned circuit. Had I then known what I know today, I might not have even tried to get on 80 meters. But I was blissfully ignorant and, with much patient advice from Jim over the phone, I finally made my first two-way contact over a full mile distance with W1YOR.

That was a long time ago. An awful lot of water has gone over Niagara since then. I suppose I could go on and mention the nine-year-old through whose relatives I landed my first job in the field, but I think this is the place to stop. Maybe some Novice struggling to get on the air can take heart and realize that sometimes the impossible can be accomplished if you try hard enough. Amateur radio has been good to me – it has led me into a profession that has been my bread and butter for over 20 years, and has provided an endless challenge to do the near impossible.

Jim W1MCR has long gone. Bob W1TUH lives in Connecticut, and I've only heard from him once in the past decade. But I very often find my thoughts turning to that room in the old boys club where a kindly old man, a spirited rival, and countless peoples' donations to the Community Fund all came together. I owe Jim a debt I can never repay, except possibly by steering some other smart alecky kid into the hobby. Somehow, though, I don't think I'll ever recapture that sense of mystery and adventure that accompanied my taking that first step. ■

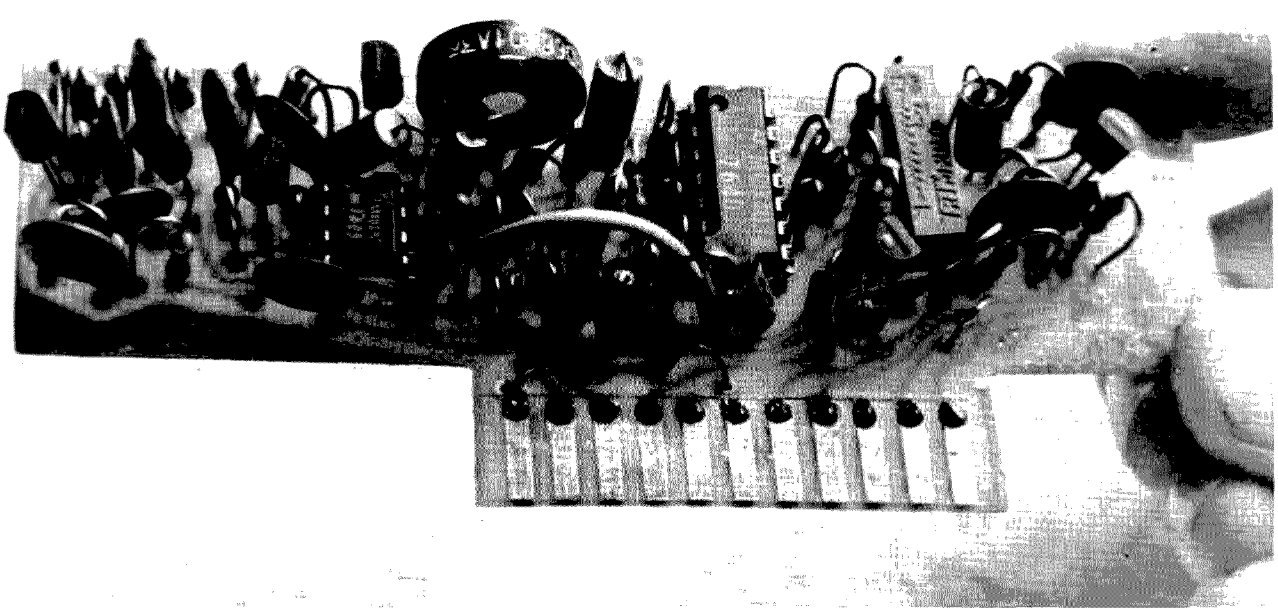
All About SCTS

-- subaudible continuous tone squelch

Subaudible continuous tone squelch has been used for years in commercial two-way radio systems to allow multiple users on a single radio channel or repeater. Most of these units use either mechanical reeds or a crystal or ceramic resonator which must be changed if a change in subaudible tone is necessary. A new resonator can cost all the way from three dollars to twenty dollars, depending on the type used.

The development of multiple op amps in one IC package has made construction of high Q active filters in a small space an easy project. A high Q active filter is the heart of this CTSS encoder-decoder.

Audio is taken from the discriminator or high side of the volume control. The high input impedance will not load the discriminator, so it is not necessary to modify the receiver circuitry. The low pass filter consisting of Q1 and Q2 passes only the audio below about 240 cycles to IC2A.



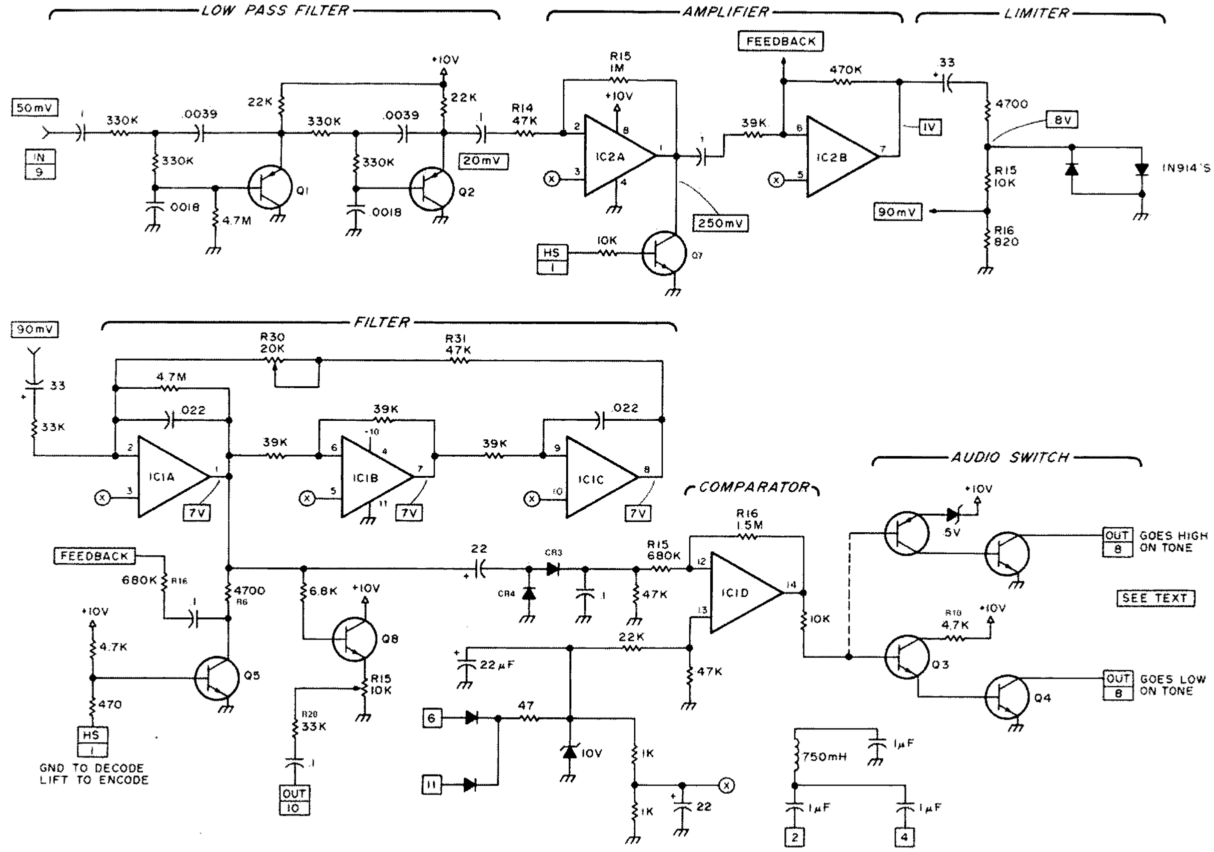


Fig. 1. All NPN — 2N3904. All PNP — 2N3906. IC1 — MC 3403 quad 741. IC2 — 1558 dual 741.

This amplifies the low frequencies and feeds amplifier IC2B, which in turn feeds a dual diode limiter. With all low frequencies being limited to .7 volts peak-to-peak, a voltage divider consisting of R15 and R16 feeds a small amount of this low frequency audio to the input of the active filter. It is most important that only enough audio be fed to the active filter so it will not limit on anything except the frequency to which it is tuned.

The active filter, which is of the "Biquad"[1] type, consists of three op amps, IC1A, IC1B and IC1C. Tuning is done using the twenty turn trimpot R30, and the course range is determined by R31. The active filter amplifies only the frequency to which it is tuned, plus or minus about one half cycle. The output of the filter is rectified by diodes CR3 and CR4. Any time the proper tone is received, the dc developed across these diodes will operate comparator IC1D. When the comparator sees sufficient voltage from the diodes it will cause Q4 to be turned on via Q3. Therefore, when the proper tone is received, the collector of Q4 will be pulled to ground. The comparator has some built-in hysteresis,[2] consisting of R15 and R16. This hysteresis will cause the transistor, Q4, to be turned on only when the output of the active filter is about six volts peak-to-peak. Once turned on, Q4 will not turn off until the output of the filter is down to about three volts peak-to-peak. This prevents the decoder from chattering on an incoming signal, thus turning the receiver audio on and off, which can be very annoying.

To cause the unit to encode, or oscillate, audio must be fed from the output of the filter back to the input. In the "mike hung up" position, Q5 is conducting hard because it is forward biased and shorts the output of R6 to ground, thus not allowing any output from the filter to be fed back to pin 6 of IC2B. Also, transistor Q7 is reverse biased, allowing incoming audio to be fed to pin 6 of IC2B. When the mike is picked up, Q7 is forward biased, shorting incoming audio to ground, and Q5 is reverse biased allowing output from the filter to reach pin 6 of IC2B. R16 is critical in value so that just the right amount of feedback will occur. This is important so the unit will oscillate on the same frequency it decodes. If IC2B is saturated too much, the frequency will be different due to the amount of time it takes the op amp to come out of saturation. The output of the active filter is also fed to transistor Q8, which serves as isolation for the audio output to the transmitter. The output level is controlled by R15, which is the emitter resistor for Q8. If the output is going to be fed into a high impedance modulator, it might be wise to increase the value of R20 so the transmitter circuit will not be loaded. Try to avoid feeding a low frequency tone such as this one into a microphone input as it is possible the microphone amplifiers will not pass such a low frequency. If possible, feed this audio directly into the modulator after the mike amplifier.

The printed circuit layout is for a Johnson 550 or 557 radio. The unit, of course, can be used with almost any radio, and has been used successfully with the General Electric Progress Line 450 units, GE Master and the new Johnson 558. When used on the 558, it is necessary to reverse the operation of the decoder as the 558 requires the ground to be released on incoming tone to unmute the receiver, whereas the 557 requires a ground to be made. This is easily done by substituting a five volt zener diode for R10, and using a 2N3906

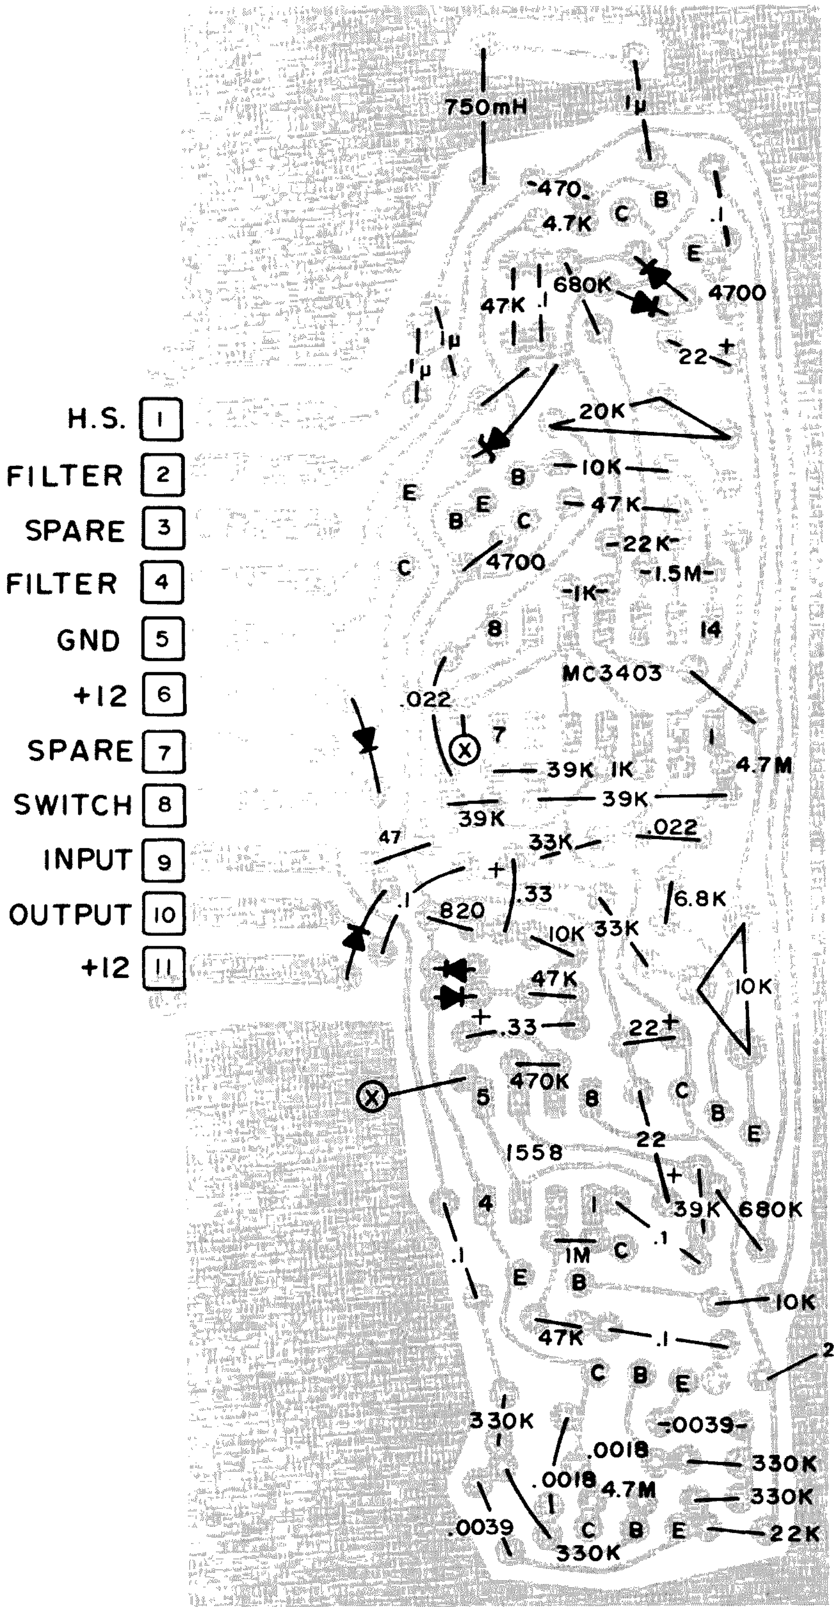

Fig. 2. PC layout.

in place of Q3. Also, when using the unit with a high input level, such as on the 558, it is sometimes necessary to put a resistor in series with the input. Depending on the peak-to-peak level of the input audio, the resistor value can be determined by experimentation. On the 558, a good value would be about 1 megohm. An alternative would be to increase R14 or decrease R15 in the feedback circuit of IC2A.

A low pass filter is included on the layout which can be used in the receiver section of the 550 or 557 to filter audio. If a filter is not wanted, then it will be necessary to install a jumper in place of the filter to provide a path for the audio in the receiver. For most applications, the encoder-decoder can be built on a single-sided board, but if it is to be installed in a 550 or 557, then a double-sided board should be made to provide pins on the plug on the component side of the unit. Wires should be soldered through as the spring connections on the plug in the Johnson won't make good contact if only the plug pins on the transmitter side are used.

It is important to use the most stable capacitors that can be found in the active filter section. The .022 uF capacitors used in this unit are Cornell Dubilier WMF1S22. The same precaution should be observed with the resistors in the active filter section. If the unit is to be used to lock up a repeater, it might be wise to increase R16 somewhat to decrease the Q of the filter so it can be activated by encoders that may be slightly off frequency. A number of these units have been constructed and are presently in use in some commercial radio systems, and they have performed quite well. There are many uses for this unit other than locking up radios. The active filter itself can be very handy for picking tones out of noise. The unit makes a stable single tone oscillator, and, by changing the capacitor values, the frequency range of the unit can be increased greatly. The low pass filter can also be used separately, as can the limiter. ■

Rotary Autopatch Dialer

-- interface repeaters and old phones

Many repeaters use touchtone* pads for control functions and autopatch dialing. Some telephone exchanges, however, still use the rotary dialing technique. With rotary dialing, the telephone circuit is broken a number of times corresponding to the number being dialed by a mechanical switch in the telephone dial. If you dial a "4", for example, the circuit is broken four times. Fig. 1 shows the timing involved in dialing a phone number. The advent of touchtone dialing makes the rotary system a bit archaic, but it is sure to be with us for some time to come, especially in the more rural areas.

To remain compatible with touchtone-oriented systems, repeaters in areas where touchtone dialing is not available may convert the incoming tone pairs to a series of pulses in order to dial the autopatch. To be convenient, the converter should be fully automatic; that is, the mobile operator should be able to access the patch, dial the number (as fast as he or she wishes), and make the call without having to go through any special procedures just because a touchtone-to-rotary conversion is involved.

The design of a *good* touchtone-to-rotary converter can be quite time-consuming. The dialer should begin dialing as soon as the first digit is entered. Since the operator can punch in the digits much faster than the rotary system can dial them, some type of FIFO, or First-In, First-Out memory must be included. The decoded tones must be stable and glitchfree before being presented to the dialer, or a misdial will occur. The point here is that designing the thing can get somewhat messy, if not expensive. A commercial touchtone-to-rotary decoder sells for about $200.

Recently, Motorola announced the MC14409 binary-to-phone pulse converter subsystem shown in Fig. 2. This chip is part of a two-chip system which is designed to replace a telephone dial with a touchtone-like keyboard. This chip is just what the doctor ordered for a rotary autopatch. The one CMOS integrated circuit will accept a four-bit BCD number and convert it to dial pulses compatible with the Bell System. The 14409 has its own onboard clock and will dial up to a 16-digit number. The numbers may be input at rates over 1000 digits/sec.

I got one of these chips as soon as I heard about it, and breadboarded the circuit shown in Fig. 3. The circuit has the following features:

1) Only 9 ICs excluding the PLL tone decoders;

2) Access patch with * for one second, clear with # for one second;

3) Automatic timeout and hangup if patch left on for more than five minutes;

4) Will take touchtone input as fast as any human can punch it in.

Circuit Description

Since this is not meant to be a construction article, the PLL tone decoder circuit is not shown. Two very good articles on touchtone decoders have appeared recently, and those who are interested may refer to them.[1,2]

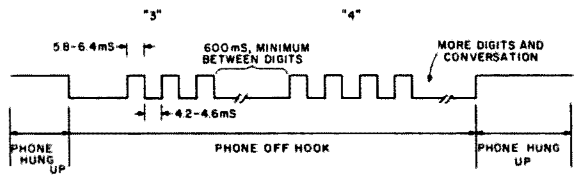

Fig. 1. Rotary dial system timing.

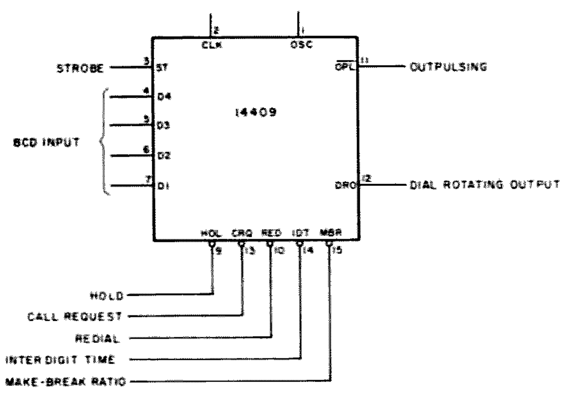

Fig. 2. MC14409 binary-to-phone pulse converter.

*AT&T trademark.

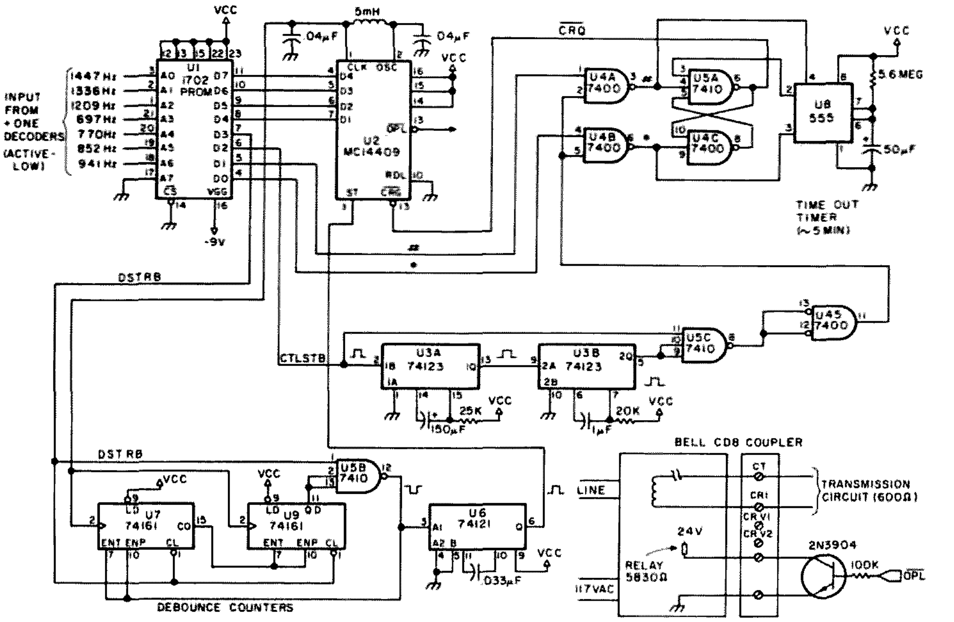

Fig. 3. Rotary autopatch. U4, U5, U6: Vcc = pin 14, gnd = pin 7. U2, U3, U7, U9: Vcc = pin 16, gnd = pin 8.

I decided to use a 1702A erasable PROM to encode the PLL outputs. Although this was a bit more expensive, I did it for two reasons – the 1702A and programmer were available, and it eliminated three or four ICs. In my opinion, every IC eliminated from a circuit eliminates 14 or 16 chances for a wiring error. Fig. 4 shows the data I programmed into the ROM. Data bits D7-D4 form the BCD output to the 14409 dialer chip. Bit D3 is the data strobe, DSTRB. It is high when any of the bits D7-D4 are high, so actually it's the logical OR of these bits. This is an example of the implementation of a bit of combinational logic (gating) with firmware (a PROM program). Bit D1 is the touchtone # and D0 is the *. Bit D2 is the control strobe, CTLSTB, the logical OR of bits 0 and 1.

The patch works like this: When a touchtone * is input (1209 and 941 Hz), PROM bit D0 and CTLSTB both go high. The 0-1 transition of CTLSTB fires one-shot U3A. After about one second, U3B fires. If CTLSTB is still present, gates U4A and U4B are enabled. Pin 6 of U6A goes low, bringing dialer chip input CRQ (call request) low. Output OPL goes high, effectively "taking the phone off the hook." The 555 timeout timer is also triggered at this time. Note that if CTLSTB doesn't remain high for at least one second, none of the above will happen and the patch will remain in the standby mode.

After the patch has been accessed and the operator hears a dial tone, he or she begins punching in the digits. Say, for example, a "7" is dialed. This causes PROM outputs D6, D5, D4 and DSTRB to go high. Whenever DSTRB is high, the debounce counters U6 and U7 begin to count. They are driven by the 16 kHz clock output of the MC14409. If at any time DSTRB goes low, the counters are cleared. This would happen, for example, if the decoders glitched on a noise spike. When DSTRB goes high and remains high, the counters count up to a count of 128, corresponding to a time interval of about 4 ms. When the count of 128 is reached, U5B and U6 generate a strobe signal to the MC14409, which causes it to input the data present in its input data lines and begin dialing. The counters are disabled on the clock pulse after the strobe is generated. (The 74161s have an *asynchronous* clear, but the enable inputs are *synchronous*. This means that if the CLR input is brought low, the outputs go to 0000 *immediately*, but disabling the counter by bringing ENT and ENP low does not halt the count until the *next* clock pulse.)

What this all boils down to is that the two counters debounce the data from the PROM and require it to be stable for 4 ms before strobing it into the dialer chip.

After the call is completed, the operator presses # to clear the patch. It, too, must be held for one second. If the mobile op is long-winded or the patch gets hung up somehow, the 555 timeout timer will hang up the patch after about five minutes by clearing the latch formed by U5A and U4C.

Doing It Legit

The dialer may be legally installed at the repeater by having the telephone company install a Bell type CD8 coupler at the repeater site. The dialer connects to the CD8 as shown in Fig. 3. A conventional audio hybrid phone patch connects to the terminals marked "transmission circuit."

I would certainly be interested in hearing from anyone who has or builds an MC14409-based rotary dialer. Best of luck with this slick chip! ■

Social Events

MACS INN ID
AUG 5-7

The 45th Annual WIMU (Wyoming, Idaho, Montana, and Utah) Hamfeast is scheduled to be held at Macs Inn, Idaho, just south of West Yellowstone (about 25 miles). This is one of the Rocky Mountain Northwest's largest hamfeasts. The registration fee for the 45th Annual WIMU Hamfeast will be S7 at the door. For further information, please contact Ronald Conley, General Chairman, WIMU Hamfeast, PO Box 30756, Billings, Montana 59107.

NEWBURGH NY
AUG 6

The Mt. Beacon Amateur Radio Club will hold their 4th Annual Hamfest on Saturday, August 6th, 9 am to 5 pm, at Stewart Field, Newburgh NY, inside hangar. Flea market and auction. Talk-in on 37/97 and 16/76. Rain or shine. Plenty of free parking. Admission $1, tailgating S1, under 12 free.

OKLAHOMA CITY OK
AUG 6-7

The 1977 Oklahoma Ham-Holiday will be held August 6 and 7, 1977 at the Southgate Inn Best Western, 5245 South Interstate 35, Oklahoma City, (405) 672-5561. Pre-registration $3.00, at the door S4.00.

JACKSONVILLE FL
AUG 6-7

The Bold City Hamfest sponsored by the Jacksonville Range Association will be held at the Jacksonville Beach Auditorium August 6-7. Vacation at our Hamfest — Florida's Friendliest. Visit our special "Solar" and "QRPp" forums. Send request for information and tables to Hamfest Coordinator, Jacksonville Range Association, PO Box 10623, Jacksonville FL 32207. For motel reservations call Ramada Inn toll free (800) 228-2828.

WASHINGTON MO
AUG 7

The Zero-Beaters ARC will hold their annual Hamfest on Sunday, August 7, 1977 at Washington, Missouri city park. Free parking, bingo, and many prizes. No admission fee or fee for parking in the trader's row. For info or tickets contact Marvin Holdmeyer WBØVPF, or Zero-Beaters ARC WAØFYA, Box 24, Dutzow MO 63342.

BERRYVILLE VA
AUG 7

The Shenandoah Valley Amateur Radio Club of Winchester, Virginia, will hold its annual Hamfest on August 7, 1977, at the Ruritan Fairgrounds, one mile west of Berryville, Virginia, on Business Rt. 7. Admission $1.50, tailgating or table $5.00. Free bingo, lots of great prizes, craft displays for the ladies and manufacturers' exhibits, refreshment stands and famous Ruritan chicken barbecue dinners. Grounds open at 8 am. The annual banquet will be held on August 6 beginning at 6:30 pm in the Pagoda Room of Duffs Rebel Restaurant on Millwood Avenue across from the National Guard Armory in Winchester VA. Admission $7 at door or write SVARC, P.O. Box 139, Winchester VA 22601.

FORT WAYNE IN
AUG 7

The Original FM Hamfest will be held Sunday, August 7, 1977, rain or shine, at the Allen County Police Reserve Center, 3022 Easterday Road, Fort Wayne, Indiana. 5400 square feet of air conditioned exhibit area, hot food and refreshments and prizes. Sponsored by Fort Wayne Repeater Association, Inc. Advanced registration $1.50 — call in to WA9EAU on 146.16/146.76, WR9ADI 146.52 or 52.525 MHz. Tickets at door S2.00. Taped route information available on 146.91 MHz. For more information and advance tickets please write: Fort Wayne Repeater Association, Inc., PO Box 6022, Fort Wayne IN 46806.

PITTSBURGH PA
AUG 7

The 40th Annual Hamfest of the South Hills Brass Pounders and Modulators will be held on August 7, 1977 from noon until dusk at St. Clair Beach, Upper St. Clair Township, 5 miles south of Mt. Lebanon, on Rte 19. Swap and shop, picnic space and swimming for the family. Mobile check-in on 29.0 and 146.52. Information and pre-registration at $1.50 per ticket ($2 at door) from Rich Eckenrode, 1410 Bellaire Pl., Pittsburgh PA 15226. Vendors must register.

LEVELLAND TX
AUG 7

The 12th annual West Texas Emergency Net Picnic and Swapfest will be held in the city park, Levelland, Texas on Sunday, August 7. Bring your own picnic basket. Registration begins at 8 am. Lunch at 12:30. Swapping all day. Tables are provided. This family event is jointly sponsored by the Hockley County Amateur Radio Club and the West Texas Emergency Net. Mobile talk-in frequency is on 2 meters only, on 28/88, the Levelland Repeater (WR5AFX). Prizes will be given this year and a $2 donation will be appreciated, but is not required for registration.

EWING TOWNSHIP NJ
AUG 7

The East Coast VHF Society and the Trenton State College Radio Club will be sponsoring a hamfest on August 7, 1977, at 10:00 am, at Trenton State College, Ewing Township NJ. Featured at 11:00 am will be the eleventh annual antenna measuring contest, on 432, 1296, and 2304. For further information, write Paul Wade WA2ZZF, 153 Woods Rd., Somerville NJ 08876, or Allen Katz, Dept. of Engineering Technology, Trenton State College, Trenton NJ 08625.

ANGOLA IN
AUG 7

The Steuben County Radio Amateurs presents the 19th Annual FM Picnic and Hamfest to be held on Sunday, August 7, 1977, at the Steuben County 4-H Park, approximately 2 mi. west and 2 mi. north of Angola, Indiana. Hamfest includes picnic-style B.B.Q. chicken and refreshments, inside tables for exhibitors and vendors, overnight camping permitted in park for those desiring to arrive Saturday, movies Saturday night, as usual. Tickets $1.00 by donation, advance registration not necessary. Talk-in frequencies 52.525, 146.52, 223.5, 446.0.

CANTON OH
AUG 7

The Canton, Ohio, Hall of Fame Hamfest (an official ARRL hamfest) will be held at the Stark County Fairgrounds on Sunday, August 7, 1977. Hamfest includes ARRL, Amateur Electronic Supply, Ken-Mar Industries, Omar Electronics, flea market, YL activities including games and drawings. Admission $3 at gate, S2.50 advanced. Under 13 years of age free. For advanced reservations contact: Butch Lebold WA8SHP, Box 3, Sandyville OH 44671. Advanced deadline July 30, 1977. For directions and information call: W8ZX on 146.19/79 (WR8ADE) or W8AL on 146.52/52. Mobile check-in prize!

AMARILLO TX
AUG 12-14

The Panhandle Amateur Radio Club of Amarillo, Texas, is sponsoring the 1977 Edition of the Golden Spread Hamfest at the Holiday Inn West, Amarillo, Texas, August 12, 13 and 14. A grand prize and pre-registration prize worth over $800 will be given away. Activities include six big tech and info sessions, commercial exhibitors, flea market, free bingo for all, two hospitality hours, live entertainment, special activities for the ladies, and demonstrations. Pre-registration $3, at the door $4. Write Golden Spread Hamfest, PO Box 10221, Amarillo, Texas 79106 for pre-registration packet.

POLSON MT
AUG 13

Western Montana amateurs will sponsor an annual Mini-Hamfest on Flathead Lake, near Polson, Montana, on August 13, 1977.

RENO NV
AUG 13

The 1977 Sierra Hamfest will be held on Saturday, August 13, 1977. Program includes: guest speakers, prizes, luncheon buffet, swap tables, QSL design contest, ladies' prizes, new equipment displays, WCARS station, swimming pool, kids' playground, rag chewing, oldest and youngest ham. Adult tickets $11 ($12 after Aug 1), ages 7 through 16 $4 ($5 after Aug 1), 6 and under free. For information or assistance, talk-in on 7255 or 146.94 simplex.

BRISTOL TN-VA
AUG 13-14

The Bristol Amateur Radio Club, Inc., will hold the Bristol Hamfest August 13-14 at the Beacon Drive-In Theatre on Blountville Hwy., 9 am to 5 pm, Saturday, 9 am to 3 pm Sunday. Tickets $1, flea market space $2. Talk-in on 01-61, 28-88 and 3980. Contact Bristol Amateur Radio Club, Paul E. Booher WA4KAS, 1221 Jonesboro Road, Bristol VA 24201.

CHARLOTTE VT
AUG 13-14

Burlington A.R.C. International Field Day will be held on August 13 and 14, 1977, at Charlotte, Vermont. Flea market both days 7 am Saturday to 5 pm Sunday. S3.00 early bird registration. $3.50 at door — write P.O. Box 312, Burlington, Vermont. Talk-in .01-.61.

FLOURTOWN PA
AUG 14

The Mt. Airy VHF Radio Club, Inc. (the Pack-Rats) will hold their annual picnic and family day on August 14, 1977, at the Ft. Washington State Park in Flourtown, Pennsylvania. Come renew friendships and talk to the hams of the Colombian Moonbounce Expedition. Time: 9 am to 4 pm. Registration $2 per family. Talk-in 146.52 and 52.525 simplex and 16/76.

PLAIN CITY OH
AUG 14

Union County Amateur Radio Club proudly presents Hamfest 77 to be held on Sunday, August 14, 1977 at Plain City Fairground near Columbus OH on St. Rt. 42, 4 miles south of 33. Hamfest includes large flea market, indoor tables for dealers, food available, free parking, and free overnight camping. Admission $1.50 advance, $2.00 at gate. Talk-in on 146.16/76. Check in (for prize) on 146.52. For more information write: Union County Amateur Radio Club, 13613 U.S. 36, Marysville OH 43040.

LEXINGTON KY
AUG 14

The Bluegrass Hamfest will be held August 14, 1977 at the Lexington National Guard Armory adjacent to the Bluegrass Field on Airport Road, Lexington, Kentucky. Grand prizes and door prizes will be given away. There will also be an indoor/outdoor flea market. Talk-in 146.16-76. Admission is S2.50 advance, S3.00 at door (includes grand prize stub). Doors open at 8 am. For more information and advance tickets write: Bluegrass Hamfest, Box 4411, Lexington, Kentucky 40504.

WILLOW SPRINGS IL
AUG 14

The Hamfesters' 43rd Annual Picnic and Hamfest will be held Sunday, August 14, 1977, at Santa Fe Park,

91st and Wolf Road, Willow Springs, Illinois, Southwest of Chicago. Exhibits for OMs and XYLs, famous Swappers Row. Ticket donation at gate $2.00, advance $1.50. For advance tickets send check or money order to Bob Hayes W9KXW, 18931 Cedar Ave., Country Club Hills IL 60477.

RIPLEY WV
AUG 14

The Jackson County Amateur Radio Club is pleased to announce the Cedar Lakes Hamfest on August 14, 1977. There will be a flea market as well as space for commercial displays available inside. The hamfest is located 3 miles off 177 at Ripley WV, at the site of the Arts and Crafts Fair. Talk-in on 146.52 as well as 31/91. The call is WD8JNU. For more information contact WB8TJA, PO Box 631, Ravenswood WV 26164 or call (304) 273-3190.

ST. CLOUD MN
AUG 14

The Saint Cloud Radio Club Annual Hamfest will be held on Sunday, August 14, 1977 from 10:00 am till closing, at the Sauk Rapids Municipal Park. Free parking and overnite parking, hot dogs and pop and chile available. Swapfest and ham gear sale. Talk in on 34/94 and 3925. For further information, contact Bill Zins WA0OTO, R.R. #4, St. Cloud MN 56301.

STURGIS SD
AUG 20

The Signal Hill Amateur Radio Club of the Northern Black Hills area will hold a Ham Flea Market from 10 am to 6 pm on August 20, 1977, at the South Sturgis Church of Christ, Sturgis SD. Talk-in on 52/52. For more information contact Dennis Painter WB0FYG, Box 759, Sturgis SD 57785, phone (605) 347-3087.

WHITNEYVILLE PA
AUG 20

The 1st Annual Tioga County, Pennsylvania, Hamfest will be held on Saturday, August 20, 1977, at the Tioga County Fairgrounds in Whitneyville, Route 6, 6 miles west of Mansfield PA, 5 miles east of Wellsboro PA. Programs include: Novice and beginner interest, space communications, FM and repeater forum, flea market area — free and large, open and covered. Admission $2 — unlicensed XYLs and harmonics free — CBers welcomed. Talk-in WR3AHN 146.19/79 . . . CB channel 5 simplex .52. Sponsored by the Tioga County Amateur Radio Club. For more information contact Denny Voorhees WA3FWQ, RD 2, Box 117A, Millerton PA 16936.

EL PASO TX
AUG 20-21

The El Paso Hamfest and Swapmeet will be held on Saturday, August 20 and Sunday, August 21 at the Mesa Inn Motel (take Interstate 10 to Executive Center exit). Saturday will feature registration, seminars, ladies' activities and banquet with a guest speaker. Sunday will feature an all day swapmeet. There will be door prizes as well as a pre-registration prize. Registration fees are: hamfest/swapmeet only — $8/head, $14/couple; swapmeet only — $2/head; total package (hamfest, banquet, swapmeet) $15/head, $25/couple. No registration necessary for children under 15. For more information write El Paso Hamfest, PO Box 4573, El Paso TX 79914.

STANTON DE
AUG 21

The 1977 Delmarva Hamfest will be held August 21, 8 am to 4 pm, rain or shine, at the Delaware Technical Community College in Stanton, Delaware. Take the Stanton-Delaware Park Exit off 1-95. Tickets $2 advance, $2.50 at gate. Tailgating and tables $2.50. Door prizes and refreshments. Talk-in on 13/73, 146.52, and 3905. Contact John Low K3YHR, 11 Scotsfield Drive, Newark DE 19713.

DECATUR AL
AUG 21

The North Alabama Hamfest will be held Sunday, August 21 at Calhoun Community College in Decatur, Alabama. For information write North Alabama Hamfest Association, PO Box 9, Decatur, Alabama 35602.

WARREN OH
AUG 21

The Warren Amateur Radio Association will hold their hamfest on August 21, 1977 at the Trumbull KSU Branch, Route 45 at Warren Outerbelt. Best site ever. Bigger flea market, all closed-in parking; parks, lakes nearby. $2 registration. Details? QSL: Hamfest, Box 809, Warren OH 44482.

LAFAYETTE IN
AUG 21

The Seventh Annual Lafayette, Indiana Hamfest sponsored by the Tippecanoe Amateur Radio Association will be held Sunday, August 21, 1977 at the Tippecanoe County Fairgrounds, 18th Street and Teal Road (Indiana Highway 25), Lafayette IN. Tickets are $2 either by mail or at gate. You must purchase tickets by mail to be eligible for pre-registration prize. Send check or money order with SASE to Bill Bayley WA9ZDI, 1021 Beck Lane, Lafayette IN 47905 for tickets by mail. Last date for mail order purchase is August 12. The Indiana Radio Club Council meeting and presentation of awards will be in the afternoon. An Emergency Forum with Bruce W9UMH will be held from 10 am until noon. Bingo for XYLs. Free coffee and donuts early Sunday morning. No additional charges for flea market operators other than regular entrance ticket. Talk-in on repeater 146.13-146.73 and simplex 146.94. Club call is W9REG.

DESOTO IL
AUG 22

The SARS Hamfest will be held on August 22, 1977, in Desoto, Illinois. Program includes prizes, food, auction. No charge for flea merchants. For more information write Nick Koeningstein, 2009 Gray Dr., Carbondale IL 62901.

MARSHALLTOWN IA
AUG 28

The Iowa 75 Meter Phone Net will hold its Annual Ham Feast and Picnic Sunday, August 28, 1977, in Riverside Park in Marshalltown, Iowa. A pot luck meal will be held at noon with a short program and a few small prizes to be given away.

O'FALLON MO
AUG 28

The St. Charles Hamfest will be held August 28, 1977 at Diermanns Lake, 4 miles south of O'Fallon MO on Hiway K. This annual event will be bigger and better with improved facilities. Prizes, flea market, dealers, refreshments and plenty of parking. Tickets still $1.00. For advance info or tickets send SASE to: Dan Corbin, 1512 Sundowner, St. Charles MO 63301.

OAKLAND NJ
AUG 28

The 550 Amateur Radio Club Fleamarket will be held Sunday, August 28, 1977, 9 to 5 pm at the Oakland American Legion Hall, Oak Street, Oakland, New Jersey, rain or shine. Admission $1, tables $3, tailgate $2. Dealers invited. Beverages available. Talk-in WR2AHD, 146.49-147.49, 146.52. For further information contact 550 A.R.C., PO Box 364, Oakland NJ 07436 or call Rick Anderson WB2QOQ (201) 684-8569.

SPRINGFIELD MO
AUG 28

The Southwest Amateur Radio Club is having its annual Hamfest and picnic at Lake Springfield, just south of Springfield, Missouri on August 28, 1977. For more info write Southwest Missouri Amateur Radio Club, Inc., Drawer B, Glenstone Station, Springfield MO 65804.

LAPORTE IN
AUG 28

The LaPorte County Summer Electronic Swapfest will be held on Sunday, August 28th, at the County Fairgrounds in LaPorte, Indiana, 50 miles southeast of Chicago. Paved midway and indoor booths available at no charge. Good food and cold drinks available. Talk-in 37-97, 01-61, or 52 simplex. Tickets $2 at gate. More information from PO Box 30, LaPorte IN 46350.

ROLLAG MN
SEPT 2-5

The Western Minnesota Steam Threshers reunion will be held in Rollag, Minnesota, Sept. 2-5, 1977. Featured will be amateur special events station WM0STR. Plans are being made for operation of CW and SSB on 80 through 10 meters, and possibly on 6 meters. QSL certificate will be sent upon verification of the log and receipt of an SASE. Send to: W8ØLRK, PO Box 596, Fertile MN 56540.

OAKWOOD GA
SEPT 18

Lanierland ARC will hold its fourth annual "Hamnic" at the Lanier Islands Dogwood Pavilion on September 18, 1977. Two large covered pavilions and large parking area for swap shop and exhibits. Food available. No entry fee for Hamnic; however, Lanier Islands charges $2.00 entry fee per car. Picnic, hiking, and swimming for the kids. First prize IC-22S. Many other prizes. Talk-in on W4IKR/4 on 3975 and .07/.67. For further information, write Terry Jones WB4FMJ, Route 1, Box 298, Oakwood, Georgia 30566.

EDITORIAL BY WAYNE GREEN

from page 4

whatever problem they were having (and I hadn't been able to get them to admit to what it was) by first stating the problem and then seeing if the mere statement of the real problem wouldn't suggest some solutions.

If the HFers are the big problem, even though the FCC doesn't want to admit it, then there are several possible ways of tackling the problem. One would be to use the historic FCC approach to solving difficult problems . . . legalize the illegal activity. This worked fine with CB. Another approach would be to try and close down HFers with FCC monitoring agents, but since the FCC is outnumbered about 500 to one, and even the most determined efforts at stopping HFers haven't achieved anything significant, this doesn't seem a reasonable way to go.

If there were any justifications for closing down the HFers, I suspect that the FCC might be able to get the enthusiastic aid of amateurs and CBers. But, with the situation of their being illegal, yet not doing any great harm, it is difficult to work up much of a program. Not a few hams may take a good look at the HF band and wonder if the time might not be coming when this will be the *only* high frequency band left for using ham gear . . . unless there is some major change in the prognosis of the coming disaster at Geneva. Do we really want to participate in helping to shut down a band we ourselves may desperately need someday?

Next I wanted to know if CB TVI complaints were tied in with illegal amplifiers. It seems that there is some agreement on this. Since the amplifiers have been made illegal, manufacturers have been making them as cheap and dirty as possible, with the end result that the linear ban has greatly increased TVI problems. The FCC answer to this is to make the laws even stronger banning amplifiers — a typical government approach to a problem.

Several manufacturers at the meeting testified that prohibition had rather conclusively proven that laws are not going to stop people making something that is wanted by the public. I suggested a try at getting the public not to want amplifiers . . . some education which would encourage CB groups to move against any local CBers using amplifiers. After all, the chap with 4 Watts output and a lousy receiver which collapses when an thin over 4 Watts comes on the

Another approach to the linear amplifier problem on CB is to change the rules and allow 1000 Watts. If that gets out of hand, raise it to 5000 Watts. The cost of 5 kW amplifiers is such that this could be a limiting factor for a while. With the coming sunspots and the more constant opening of the CB channels for skip, a bunch of kW signals should be most interesting. Remember that the FCC has no mandate whatever to provide interference-free bands for CB.

Legalized amplifiers would make it easier for the FCC to make sure that the moonshine linears we are seeing these days would be killed off. Making something illegal doesn't stop it — it just makes it attractive and forces people to buy junk instead of goods which have withstood the test of the marketplace.

If the FCC stopped licensing CBers, they could cut the staff at Gettysburg in less than half. I realize that this is contrary to every law laid down by Parkinson and thus can't happen . . . but I like to dream. Just because it is serving no useful purpose is no reason to stop it.

Let's take this even further. While I accept that we do have to have licenses and license exams for amateurs, I don't agree that the tests have to be given by the FCC. The ARRL would dearly love to take over giving the license exams, and I'm sure this would work out as it has in several countries where the national club issues the licenses . . . no membership in the club, no license. And to a club whose main source of income is advertising from a magazine, government-enforced subscribing to their magazine is most attractive.

Even though the FCC found what amateurs had long known, that the Conditional class license was being cheapened by cheating, that doesn't mean that there is no possible way for hams to self-administer the exams. I'd like to see ham clubs with enough interest to run classes be permitted to give exams and issue licenses. With any exam supervised by a minimum of three licensed amateurs of an equal or higher grade than the examinee, we should have little trouble with cheating. A club's reputation would be on the line.

The FCC could require a fairly tough training course and make the clubs toe the line. It would still take far fewer people than they are using today to examine tens of thousands of applicants. The FCC could then take some of the people released from examining us and [illegible]

RTTY

This issue of *73* is dedicated to amateur radio teletype, or RTTY. Even if you are not a RTTY enthusiast, the special articles should be of interest to the technically inclined. The winner of the Call For Papers competition of a few months ago is in this issue. The article, "So You Want To Get Into RTTY?", by Richard Parry, contains information for beginners and experienced operators alike. A fine article, "Design An Active RTTY Filter," by Pete Stark, is also presented. This article is not only for RTTY operators, as it describes basic design techniques for active filters — also used by CW operators and audio enthusiasts. Enjoy!

There is always some trepidation about starting out on a new mode, such as SSTV, RTTY, or OSCAR. In the case of RTTY, it's not really that hard, and the advantages are many. Believe it or not, many hams have mike fright, and conversations over the air often degenerate into a tiresome routine of signal strength reports and local weather information. Typing on a teletype machine is slower paced than talking — it gives you time to organize your thoughts, just like writing a letter to a friend. And, of course, there are always those pictures (pix) to exchange. RTTY art is enjoyed by many operators; just tune in on 20 meters on Saturday morning about 14.09 MHz and see. Some of the pix are masterpieces and take over an hour to print!

I was introduced to RTTY by a friend and fellow ham, Ken W2PSU. He said that "there is always something to do" when operating teletype. Think about it; on phone, most operators just sit and listen during a QSO, having tuned up and organized before answering a call. Could get boring, unless you're locked in a pileup. There is always something to fiddle with while "printing" a QSO. You can pretype your response to questions on paper tape with most systems, prepare picture tapes, adjust your printer, or whatever! Never a dull moment — just watching the QSO type out in front of you is better than listening, in my opinion.

It really does not take a roomful of gear to gain an introduction to the world of RTTY. If you already have a transceiver (HF or VHF), it can be done for less than $100. First you will need a page printer and keyboard. There are a multitude of these available; a common device is the Teletype Corporation Model 15. The larger Model 19 stations with paper tape equipment are based on the ubiquitous Model 15.

Printers are available for under $50. I picked up a classic Model 15 with answerback and internal loop supply for $35 at a flea market this summer — they can be had for less. Check flea markets, or ask a ham who is into RTTY, as he may have a second, unused printer around.

After obtaining and converting the printer, a terminal unit, or TU, is required. The TU converts the received frequency-shift tones into dc pulses that drive the printer. TUs can be very simple. A good one is not all that expensive. This month, almost by accident, I obtained a TU kit from the Flesher Corporation in Topeka KS. Dubbed the DM-170, this $39 kit outperforms much more expensive devices. It takes an hour to build, and is on a 3" x 5" PC board! (Check my review in this issue.) So let's see, we're up to about $80 for a TU and printer — add a loop supply to drive the printer (definitely a junk box project) and you are ready to copy RTTY signals off the air! In order to transmit, a method for keying the transmitter from the keyboard is required. The practice today is to use audio frequency shift keying, or AFSK. This technique involves generating two tones which, when shifted back and forth, provide a means of coding the keyboard characters. In most cases, the audio tones can be fed directly into the microphone input of an SSB transceiver. A suitable AFSK generator can be built with one 88 mH toroid and about $5 of new parts. That's it! A basic RTTY station is guaranteed to produce hours of operating pleasure, and may be expanded as time and money permit. RTTY lends itself to computerization like no other aspect of hamming, and there are loads of digital operating aids that can be added. Some of these special projects are described in this issue.

NOTE TO CORRESPONDENTS

I have been receiving volumes of mail lately, requesting everything from writers' guides to conversion information on 1934 receivers. As I have said, we do our best to answer all correspondence, especially from authors. A problem exists, however. Many of the requests for information come with no return postage or SASE. Most publishing houses immediately file such correspondence in the circular out basket. In the future, I will not respond to unsolicited requests for information unless an SASE is provided. Manuscripts rejected with no return postage will be saved, but not returned unless postage is provided by the author. I don't think you would bear such expense as postal rates spiral; why ask your friendly amateur publication to do it? Thanks!

NEW TRENDS

My experiments on 10 GHz with the Gunnplexers slowed down this month for several reasons. I am refining my system with the VHF Engineering receivers, and ran into a parts bind. The mail advertisers in *73* are fast, but not that fast! The details of my experiments will be along soon, however. Who knows, RTTY on 10 GHz? I did construct a set of active filters for my RTTY station, using Pete Stark's design guidelines. Some type of filter is needed before the discriminator in a RTTY TU, and active filters are the way to go. Most older designs use 88 mH toroids, which require careful and tedious tuning. With an active filter, a variable trim control can be used to set each stage in a matter of minutes. It was a fun project — the filter is now embedded in my terminal unit. I usually get a chance to operate on weekday evenings, especially when 20 is open. Look for me between 14.090 and 14.1. I'd like to print you!

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz.
OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz.
Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

CARF

Canadian Amateur Radio Federation, Inc.

CARF NEWS SERVICE BULLETIN

In reply to a CARF request for a special callsign prefix to commemorate Queen Elizabeth's Jubilee year (25th year of her reign), DOC has announced that Canadian amateurs may use the prefix "CY" for VE and "CK" for VO station calls for the balance of this year.

DOC announced third party traffic agreement and reciprocal operating privilege agreement between Canada and Columbia, effective May 25, 1977.

LETTERS

TRANSIENT SWR

I read with interest and disappointment a recent article by J.A. Murphy, "Transmission Line Primer," *73*, June, 1977.

It is unfortunate that instead of enlightening your readership, the author has simply succeeded in muddying the transmission line waters even further. After reading a dreary succession of articles which attempted to explain transmission line theory, standing waves, and reflective power, I have concluded that one of the reasons that nothing definitive has appeared in the amateur literature is that a detailed understanding of the physical mechanism involved simply does not matter.

That is, most hams know that a high vswr is undesirable, and that efforts should be made to match antenna to transmission line. By following these simple rules, in most instances, a satisfactory amateur solution can be obtained without knowing much more.

Nevertheless, Mr. Murphy, apparently a professional engineer, should know better. In substance, he has simply confused the transient solution with the steady state solution. His simple analysis is correct as far as it went, but he incorrectly generalized his result.

Mr. Murphy makes use of a dc step function to describe what antenna engineers would call a pre-cursor wave front. Initially, the transmitter supplies a certain amount of extra energy to the transmission line until the first reflection makes the transit from antenna load back to transmitter. Until that time, of course, the transmitter does not "see" any change in loading due to antenna/transmission line mismatch. A first reflection does represent real power, and that real power is used to establish a standing wave. The presence of the standing wave alters the input line impedance so that the transmitter now "sees" a different load condition, and *thereafter* delivers less power to the line.

Standing waves, by and large, represent a steady-state condition, but standing waves do not represent a continuous back and forth reflection of real power. The phase relation between current and voltage in a standing wave pattern is indeed 90°, with a consequent zero power factor. You can see that this must be so if you consider the case of a shorted line. At the shorted end, current is at a maximum while voltage is at a minimum. If you plot current and voltage as sine waves, and superimpose a minimum point on one curve with a maximum on the other, you will appreciate that a 90° phase shift has occurred at the load. The same reasoning, of course, applies to the case of the open line – maximum voltage with minimum current at the load. The equations derived by Mr. Murphy do not account for these conditions, resulting only in trivial solutions when the line is open or shorted.

The transient effect described in the article is rarely observed in practice by amateurs. It would take an almost lossless and relatively long transmission line to produce noticeable transient effects on transmitter loading. However, when discussing fast rise-time digital pulses in computer circuits, distortion of the leading pulse edge (caused by reflection) can be most important. But this example merely serves to confuse the issue. It is too bad indeed that the article didn't develop the steady-state solution and avoid the usual mumbo-jumbo about effects of loss, phase and group velocity, and other relatively arcane considerations which add little to an understanding of standing waves and reflected power.

I suppose what is really needed here is a definitive article by a recognized expert in the field who will, once and for all, put some of this nonsense to bed.

Comments, engineers? – J.M.

APPRECIATION

Kudos to Craig Anderton for his fine article concerning mail order in the July issue of *73*. As someone in that business, I can empathize with the entire story. If everyone who shops by mail would only read Craig's story, it would save many people time and effort, not to mention money.

Al Smith WA2TAQ/WA4LDW
Merrick NY

HOW FAR WEST?

Most cases I don't like to complain too strongly, but after waiting such a long period of time, I can't hold off any longer.

I have been a subscriber to *73* for a few years now, and during that time I have been reading a column entitled "Looking West" by Bill Pasternak WA6ITF. According to my definition of the term, "West" should include many states in the western portion of the country. I don't believe the amateurs in New Hampshire would consider their state as the only state in the "East." Therefore, by the same token, it seems a bit unfair to classify California as the only state in the "West." According to my qualifications, I would say all the states in the "West" would be those in the 6th and 7th call areas.

To the best of my knowledge, since I have been a *73* reader, I have yet to see any coverage of amateur activities in any area other than California in the "Looking West" column. In fact, within the past 8 to 10 months, we have sent Arizona news to Bill. Before I recently acquired my new trifocals, I sure hope I haven't missed any western ham news in "Looking West" (wherever that is) in your magazine.

Wm. Oliver Grieve W7WGW
Phoenix AZ

What say, Bill? – J.M.

SERVICE NETWORK

This is to inform you about the activities and the existence of the Guatemalan net, "TG Amigos del Mundo" (TG Friends of the World).

It was created in June 1976, on the 17th, to be precise, and this day was the first day of labors. It's already been over a year since it was initiated, and on June 17, 1977, we had a party at the American Club of Guatemala, to celebrate our first anniversary.

The net was created to thank the many friendly countries in the world that sent help and assistance to Guatemala during the past earthquake (Feb. 3, 1976), and also to correspond with other countries which have nets that have so many times helped Guatemalan ham radio operators.

Until that date of June 17, 1976, you had to try luck on the different bands to be able to catch a TG station, but now you know that on 7.085 MHz, from 02:30 to 03:30 GMT, Monday through Friday, and from 16:30 to 17:30 GMT, Saturdays and Sundays, you will be able to find TG stations.

Since the initiation of the net, we have handled about one hundred emergency traffic messages. In January 1977, there was a need for medicine in a hospital in Nicaragua, and through the net we coordinated to get the medicine. After approximately two hours, such medicine was taken on a private plane from Guatemala to Nicaragua.

There was another time, unfortunately I don't *remember* the date, when there were floods in Honduras. For 30 hours the Guatemalan net stayed QAP, working on different shifts of one hour each, until we were able to give the necessary help to the Honduran people.

The founders of the net are: TG9LN Mrs. Ana Maldonado, TG9VD Mr. Rafael Maldonado, TG9QV Mr. Ricardo de la Vega, TG9RL Mr. Rony E. Liang, TG9RC Mr. Rodolfo Casas, and TG9LX Mr. Luis Stolz.

Guatemala, C.A.

QUALITY OR QUANTITY?

Am I an old-fashioned snob? I never thought so, but apparently, according to Mr. Magness' letter (July '77, "More Tech Debate"), I must be.

I have nothing against Technicians, and certainly not Novices. I had as much, if not more, fun as a Novice as now. *But come on!*

I'm a 16 year old kid who sweated my brains out to get my General ticket. I got my Novice in Oct. of '75, and after failing the General theory in Dec. '75, I finally passed it (second try) in Jan. '76. When I failed, did I beg for an easier test? *No!* I just went home and studied a whole lot more.

At the present, I've failed the Advanced twice, but am I yelping for an easier test? *No!* I'm a DXer, and I see that the Advanced ticket is quite a point in your favor for DXing. Someday, I'll pass my Advanced, and earn new frequencies to use, *but I sure don't want them given to me!*

In explaining to my friends at school some of the differences between CB and amateur radio (besides power, frequencies, etc.), I tell them how you get a CB license by filling out an application and sending it in to the FCC. However, in order to get a ham ticket, you must pass an exam, consisting of being able to copy the International Morse Code, and then you must pass a test on electronic theory. They understand that ham tickets aren't given away, but do we?

OK. Say that the 13 wpm test is too high. Has this stopped thousands of *determined* persons from getting their General tickets yearly? And again, OK. So what if there is a high rate of Novice and Tech dropouts? If they don't want to work for their tickets, should we take it on ourselves to give them to them? Do we want quantity or quality of amateurs? If (and when) they drop out, *have we lost anything?*

I spent a lot of money on my equipment, too. Out of my own pocket (by my parents' decision). I know that since I had to shell out the cash for my rig and antennas, I'm not as likely to abuse it as someone who had it given to them (because I know what it's going to take to replace it). But do I fuss because I can't use frequencies allocated to Advanced or Extra class licensees? *No!*

When I got my Novice ticket, I knew exactly what I wanted to shoot for (General and above), so I buckled down and put out some effort. I expected nothing to be given to me, *and it wasn't!* I had to pass the 13 wpm code test like any other guy who went in for the test.

If we're going to start easing the requirements on exams to encourage CBers (and the public) to become hams, then why not just give 'em all their Extra, and be done with it (and amateur radio) in one big step.

Maybe nobody listens to kids, but after all, I'm a ham just like you, and we kids are the ones who are going to have to live with the laws you grown-ups make.

I'm sure, and I think you'll agree,

that if CBers had to pass an exam to get their licenses, there wouldn't be the problem that there is today with them. The ones who studied and passed their tests in order to *earn* their privileges would respect their right to operate, and wouldn't abuse it (or allow anyone else to).

But look at us! *We're hams!* We're really above the problems caused (and endured) by CBers. And what are we doing? We're lessening the requirements for our licenses so that more people can be hams!

I'm just as willing to welcome newcomers into ham radio as anyone, but if I had my choice, I'd rather be welcoming hams who have earned their new privileges.

Mark A. Clark WB4CSK
Fayetteville TN

WR7AFC

The idea was born over three years ago, and on Father's Day of this year, a group of fathers made this reality become true, when WR7AFC, Arizona's Finest Channel, began operating from Mingus mountain near Prescott and Cottonwood, Arizona. Operated by the Mingus Mountain Repeater Group on 147.600 input and 147.000 MHz output, coverage promises to be excellent from Phoenix to Flagstaff and almost all areas of Northern Arizona.

In fact, California repeater operators take note — many of the mountaintop (not bumps) repeaters are being operated at elevations in excess of 7000, 8000, and even 9000. Attention, Jack Anderson: Come out to Arizona and see some of our high-rise mountains, but don't look down.

Wm. Oliver Grieve W7WGW
Phoenix AZ

TRIAL SUB

Your comments about the ARRL are particularly disturbing. Apparently you do not have very good access to the facts, since many of your comments are out in left field. I realize that you are trying to sell magazines, but you would do better to stop knocking the competition and join with them to really do something for amateur radio. Split factions never do any good for the overall good. I criticize the ARRL in letters to them all the time, but I don't go around saying things bad to other folks.

Your conflicting comments regarding *CQ* in your last editorial make it readily apparent that you are using them to sell magazines. I have a number of friends that do not subscribe to *73* simply because of your lousy editorials. I think you would do much better to join a common cause to help promote amateur radio instead of trying to sell *73* through your editorials, especially when you don't know the facts. (And how about giving the new administration at ARRL a break and stop bringing up this old stuff from years ago?) They make mistakes, but a look at the annual report shows just how much they are really doing for amateur radio.

This subscription will be a trial one for me.

D. Paul Gagnon N6MA
Camarillo CA

Thanks for the chance, Paul! — J.M.

PUBLIC FIRE

The other night while talking over beer and crackers with some amateur friends of mine, we came to a horrible prediction for amateur radio: Amateur radio may no longer be a hobby in the year 2000, due to public opinion.

One of the fellows (an Extra) mentioned the fact that amateurs take hundreds of frequencies for granted. VHF and UHF channels have very sparce activity, while only a few kilohertz away commercial channels are becoming overcrowded.

Think about this: You're watching the six o'clock news and up comes a story on the overcrowded conditions with commercial two-way radio. A telephone company rep tells how four or five megahertz of space isn't even being used by "hams" or "amateurs." He goes on to say how many hundreds of calls should be handled by their microwave links. He finishes, saying, "Amateurs are a stumbling block for the advancement of the radio art."

We may laugh now, but this could happen. Several co-workers are expressing displeasure in my hobby that used to excite them. After the Jack Anderson article, a few would say, "Is it true you hams have thousands of frequencies while CBers have a fraction of that?" One comment really hurt me: "What gives you guys the right?"

About a year ago, the ARRL made a big noise on how they would provide Public Service Announcements to broadcasters, new exciting movies, and code kits.

Where are these magical materials from the League when we need them? The radio station I work for broadcasted the PSAs five or six times, hardly enough for any listener to be convinced amateur radio is the "in" hobby. I still have not seen any PSAs on local TV.

Here's my point. Hams are coming under public fire. A few citizens have realized we do provide a public service, autopatching traffic accidents, or passing traffic. But, the general public can be turned against us, and so can legislators.

Why can't the League buy some prime time commercials during a television special? Why can't local clubs purchase commercials telling of the upcoming hamfest? Why don't hams get off their asses and show the public how exciting this space-age hobby can be?

Now is the time to get a club president of the local ham group to speak to the Chamber of Commerce. Insist on becoming a recognized community organization. How about an OSCAR setup at the shopping mall for two days? Tell how local amateurs have put the town on the map with their contests, QSL cards, and hamfests. Enlist the support of the mayor, the police chief, the City or Town Council.

Recently at a club meeting, the local group was having a field day on Jack Anderson. "He's a clown," "What a joker," were the comments in the meeting hall. Then I mentioned how amateurs should send letters to the Office of Telecommunications, White House, protesting comments made about our hobby. Then follow up with another letter to Congressmen and the President. The bunch of people didn't even hear me. They just went on complaining about the raw deal hams got in a newspaper article.

I know that my next-door neighbor doesn't consider Jack Anderson as a clown. I think most of the nation would agree. I respect him as a reporter. So what's the public supposed to think when this man tells us hams are getting special favors from the FCC?

I love ham radio, enough to write six letters to Washington, D.C., and one that was printed in the local paper about ham radio. I am handling more traffic for reluctant neighbors, and explaining my HT and autopatch to anyone who wants to know.

Hams have to do a "sell" job in preparation for the WARC in '79. Now is the time to become a community leader and show off your station to your neighborhood, to your kids, your kids' friends, to everyone. Once they get a glimpse at your QSLs, CB will seem like a toy.

If I have gotten the reader all fired up, great! Grab some paper and ask our President why an advisory agency that is supposed to coordinate military radio frequencies is hinting at the FCC for more CB frequencies. President Jimmy Carter or Office of Telecommunications, The White House, Washington, D.C. 20030.

You might want to send a radiogram to your Congressman, and good luck with the Chamber of Commerce. Unlike most hobbies, ours is regulated by the people, and for the people.

Dave Sweigert WB9VKO
Fort Wayne IN

You might drop Mr. Baldwin at the ARRL a note endorsing Dave's suggestions. I wonder what the effect of 100,000 letters would be? — J.M.

BELIEVER

I purchased your 13 wpm tape approximately 1 month ago and spent 1½ hours/day 7 days a week and received my General ticket 6/17/77.

I have used 3 different makes of code tapes besides yours, but they always brought me to the mental barrier of 10 wpm. I could not go beyond this until I used your tape.

You made a believer out of me. Keep plugging your method. It works!

Ed Hegyera WB9VZU
Kenosha WI

HERE SHE COMES

Please be advised that amateur radio station K2BR ("Boardwalk Radio") will be operating from the Miss America Pageant in Atlantic City, N.J., from September 1 to 10, 1977. Frequencies: CW — 3560, 7060, 14060, 21060 kHz; phone — 3960, 7260, 14290, 21390 kHz; Novice — 3720, 7120, 2112 kHz.

The station is under the sponsorship of the Southern Counties Amateur Radio Association (SCARA). Please QSL to N2NJ (ex-K2JOX).

Henry G. Rainville WB2QXX
SCARA/Miss America Pageant Coordinator
Ventnor NJ

QRP

Hurrah for K6JQD! I just received the June issue of *73* and am very impressed with the letter from K6JQD concerning power levels. I certainly do agree with his views, but for other reasons than those stated. I have been living in Germany for several years and am aware of how high-powered American ham stations are affecting the overseas ham community, and it does not look good. I also am in about the same position as many of the European hams, in that I am not able to run high power or a very efficient antenna. I am afraid that not many American hams appreciate what is available to them at very reasonable cost. They are also giving American hams a black eye, although it may not be obvious that this is so.

Like many other hams in Europe, I am only able to run 200 Watts or so, and an inefficient antenna, and of course this limits to some extent the number of contacts I can make. This situation is not really that disturbing to me, except for the fact that when the receiver is turned on, about the only stations I can hear are lots of high-powered stateside stations with 1000 Watts and a big multi-element beam punching through with extremely strong signals which override many of the other stations I might like to work. Oddly enough, it is very difficult to work those strong stations; I suspect they only listen for loud stations and won't come back to anyone who does not have at least an S7 or S8 signal. It is very frustrating to call CQ

for hours and not receive a contact due to the stateside QRM or to hear a desirable station but not be able to work it due to the frequency being overloaded with super-powered stations. Then, of course, in the back of one's mind is the fact that you know you don't have a chance with low power (200 Watts) and a vertical antenna. For me, this is merely frustrating, but for a native European (or any other native for that matter), it must be even worse, considering that his knowledge of English is probably limited (along with his understanding of the American ham scene), and then he's limited in power and antenna and hears nothing but strong stateside stations on frequency. I speak German fluently and have had many nice eyeball QSOs and 2 meter QSOs, during which various opinions have been expressed, concerning the mess on 20 meters primarily. Many hams in my area hold a rather low opinion of the American ham and simply do not work HF anymore, or as little as possible due to this situation. One must realize that most foreign hams have had to struggle for a long time to scrape up the cash for a 200 Watt rig and have done a lot of fighting to put up any kind of antenna in the limited space most of them have available. It is then no wonder that many foreign hams are resentful when so many American hams on the air state, as if it were nothing, that they are running 1000 Watts with a multi-element beam high on a tower; such things are only wild dreams to most hams over here. I believe that the image of the American ham is tarnished enough without all of the high-powered stations rattling the ears of other hams all over the world. I would not want to introduce a blanket low power limit; however, after all, as you stated, there are cases where high power is needed, but in most cases it is not necessary.

I am afraid that many hams these days are using high power to cover up poor operating practices or laziness. After all, it does take more effort to dig a little for the weaker stations and that is a shame, for many of those weaker stations could carry on a good QSO, too, if others would put forth a little more effort. Those weak stations out there are hams, too, although some operators seems to think they are little more than sources of QRM. I believe that most of the hams running high power could make do with less power if they would put on their headphones and sharpen up their operating skills.

I believe with WARC coming up we American hams cannot afford to give other countries a bad impression of ham radio in the US, but I am afraid that is just exactly what we are doing. We can do all the goodwill work there is to do and still come up on the short end of the stick if we do not watch our manners on the air.

In closing, I hope that others will respond on this subject and I am very pleased that you offered to open the letter forum to comment. This letter will no doubt stir up a hornets' nest, but I believe that there are many hams out there who will agree with me and K6JQD.

Richard J. Molby WB7NZG/DA1DB
HHB 3rd BN 84th Arty
APO NY 09176

I agree, Richard! It's a shame that the kilowatt signal appears to be the norm on the HF bands, at least in the phone section. Why run 1000 Watts when 100 will do the job? Not only is this practice discourteous to our foreign neighbors, but it cuts the moderately powered stateside stations "out of the action." Most of my low frequency operating is on 20m RTTY. Very few stations run over 200 Watts, and get out just fine. I run 75 Watts out of necessity, and work everything I hear. Now, I'm sure that there are those who will point out that the RTTY section of 20 is not as crowded as the phone areas. True, but how much more usable space would be available on phone if much of the power-induced QRM was eliminated? Think about it. — J.M.

ENJOY

I enjoy *73 Magazine* immensely. Pity that due to my lack of knowledge of the technical end of it, I cannot really absorb it all.

I did manage to pass the Novice exam, due in part to the excellent code tapes, and a great amount of study.

Electronics really did not interest me until the advent of CB SSB. Then I decided there had to be a choice of remaining or advancing. I will truthfully state that the knowledge does not come easily, as first I had to overcome my dislike of the electronics bit, but in the very near future, I intend to pass the Element III exam. I was extremely interested in the articles on conversion of 11 meter rigs to 10 meters, as I had a suspicion it could be done. Keep up the good work and fine articles.

Leon S. Greenwood WB3HEV
Philadelphia PA

Stay tuned for additional conversions, Leon! — J.M.

MORE MAIL

The mail-order article by Craig Anderton (*73*, July 77) was unusually warm to read. It was upbeat, informative, with empathy for both the seller and the buyer. I hope that enough readers paid the due that it so richly deserved, and will benefit by the insight Mr. Anderton provided to enhance understanding in the cold, detached world of consumer economics.

Bob Grove WA4PYQ
Davie FL

WHO CAN LISTEN?

Have you noticed the item in the Happenings column of the July *QST* (p. 67) which states that hams in Indiana have "won" something by being exempted through legislation from the prohibition in bill SB454 against the ownership of receivers capable of copying the police bands for mobile or portable use?

I have always understood that the civil rights of American citizens included the reception of any radio transmission which is within the ability of an individual to receive it. Transmitted signals are within the public domain, and it is the obligation of the transmitting party to achieve security of information through codes, ciphers, cryptography, or whatever means are available. From this perspective, it concerns me greatly that a state agency can include legislation and criminal punishment as means of ensuring the security of its radio communications.

What have hams in Indiana won if they do not have the right of all citizens to listen to any signal which causes current to flow in their antennas? Is tnis a police state? What do the authorities have to hide? Can this be done at the state level?

I am writing to both the ARRL and the Governor of Indiana. I hope that the ARRL and you can come down hard on Indiana, because this activity is clearly out of the authority of state government and is clearly discriminatory if not applicable to all citizens.

Ted Edwards W1AJS
Sugarloaf PA

Ham Help

This is to request your readers to help us with our "Project Lifesaver" radio effort. We need parts and advice to enable us to adapt an ARN-6 system for finding people caught in blizzards.

We are solid stating the following tubes: 2050, 0D3, 6L6, 6V6, 6SJ7, 12SK7, 12SY7, 12SW7, 6SA7, 6SG7, 6AC7, 6J5, 26A7 — and we need a manual or at the least a schematic for ARN-6. Also, we need a 3-stack carbon pot (60k, 10k, 33k).

Ellis County Volunteer
Emergency Services
Box 522
Hays KS 67601

I have a vibroplex key with which I would like to become proficient (prior to on-the-air use). However, after scrupulously cleaning the contacts on the key and installing new batteries in the Heath transistorized code practice oscillator, I'm still getting "dits" that are different in frequency (pitch) than the "dahs" on a straight key. Anyone have a "fix" for this?

James R. Theby WB0HZX
4912 Brockwood Drive
St. Louis MO 63128

I am in need of a tube layout or a schematic for a Jackson Model CRO 25" oscilloscope. It is manufactured by the Jackson Electrical Instrument Company of Dayton, Ohio, which is now out of business. I am missing two tubes which have 8 pin sockets — they control the intensity. Any help would be greatly appreciated.

John M. Matz
741 Schuylkill Ave.
Pottsville PA 17901

Many would-be hams don't know where to turn for classes to help them obtain their Novice tickets. Therefore, we are compiling a list of people or clubs conducting Novice classes throughout the country. We would appreciate it if these people or clubs would send us the following information about their classes: club or person sponsoring the class (if club, specific person who should be contacted); address; telephone number; whether classes are held year-round or at specific times of the year; any additional information.

Please keep us informed of any changes in your classes, so our list will be as current as possible. We ask anyone asking about information concerning classes near them to please enclose an SASE.

Bob Billson WA2TXY

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

This month we will discuss the connections required to interface a Model 15 or 19 machine to a RTTY loop. Once this has been accomplished, the machine can be used with a terminal unit to receive and print RTTY signals.

I will assume you have acquired a Model 15 page printer or its big brother, the Model 19. This is a useful assumption for several reasons. First, it gives me a chance to talk about something I know. Second, the Models 15 and 19 constitute the foundation of ham RTTY. Setup of other machines can be based on what we cover here. Third, if you are rich enough to afford an ASR-32, you don't need *my* help!

The Model 15 machine consists of two major parts, a keyboard and a printer. Separate electrical circuits are provided for both devices; however, they are driven by a common motor. Some Model 15 machines have optional goodies, such as built-in loop supply, answerback, and assorted control relays. In any case, all the electrical connections are terminated on a terminal block on the right side of the machine, when viewed from the front. The terminals are available when connecting the keyboard and printer. Normally, the selector magnets in the printer are connected in series with the keyboard contacts; thus everything typed will be printed locally.

There are three connections which must be made to the Model 15 to get it running: (1) 115 V ac for the motor; (2) loop current for the selector magnets; and (3) keying circuit for the keyboard. We will cover each of these in turn.

To begin with, take a look at the motor in your RTTY machine. If there is a wheel with black and white stripes on one end, with levers protruding, you have a governor motor. The first thing you will have to do, after applying power, is set the speed of the motor. Good luck! You need a tuning fork and lots of patience. Most motors are synchronous, and remain accurate through the good graces of the electric company. To get the juice to the motor, connect the ac line to terminals 21 and 23 on the terminal strip located on the right side of the machine. See Fig. 1. You should use three-wire cable, and ground the chassis of the machine. Now, when you turn on the line switch, the motor should start, and all kinds of levers and gears should clatter. This is called "running open." Now — turn off the machine and unplug it.

Take an ohmmeter and lay it across terminals 45 and 46. There are two selector magnets, each with a resistance of 105 Ohms. If they are connected in series, total resistance is 210 Ohms and operation is for 20-30 mA of current. Parallel connection, with a resistance of 52 Ohms, is designed for 60 mA loops. If your magnets are in series, change them; see Fig. 2. A loop supply capable of delivering 150 volts at 60 mA is needed. Fig. 3 shows a typical circuit. Notice the series resistor. If it was omitted, the current in the loop would be:

$$I = \frac{E}{R} = \frac{150}{52} = \text{about 3 Amps!}$$

Don't forget that resistor! Without it, the selector magnets will burn themselves up. By the way, required wattage for the resistor:

$$W = E \times I = 150 \times 0.06 = 9 \text{ Watts}$$

Don't skimp on size, either!

Now, take this power supply, which we will call the "loop supply," and connect it to terminals 45 and 46 (see Fig. 1 again). Plug the machine back in and turn it and the supply on. Things should run quietly now, without all that clatter. This is not running "closed"; it's just working as it should.

One more hookup and you will have yourself an electric typewriter. Connect some leads onto terminals 32 and 34 (start to wear out Fig. 1). Connect these keyboard leads in series with the loop. Fig. 4 illustrates the point. Now turn everything back on (I hope you turned it off while your fingers were in there), and everything you type on the keyboard should print on the page. Not exactly a Selectric, but still neat, right?

Next month we will discuss how to use the machine to receive signals. Familiarize yourself with the keyboard and special functions. It might be advisable to lubricate the mechanical parts, paying special attention to the oil cups on the motor and main drive shaft. Under no circumstances allow oil to contaminate the printer contacts. To do so will result in erratic transmission. See you next month!

I hope you are enjoying the RTTY Loop. As you can see, this issue of 73 *features RTTY operations, so if you are into RTTY, keep reading! At this point, a little pitch for the* 73 RTTY Handbook, *edited by the 73 staff, is in order. This book has information for beginners and seasoned operators alike, and is a must for all RTTY enthusiasts. This reference is up-to-date, featuring circuits based on op amps, FIFOs, and UARTs. For $5.95 you can't pass it — order from the 73 Radio Bookshop. Another publication will be of interest to RTTY enthusiasts: The* RTTY Journal, *published about ten times a year, is exclusively RTTY oriented. It features a classified section loaded with teletype gear. Subscription price is $3.50 (amazing) a year, and subscriptions may be obtained by writing* RTTY Journal, *P.O. Box RY, Cardiff-by-the-Sea CA 97002. (This is not a paid commercial — just a helpful tip from one RTTY afficionado to another!) — J.M.*

Nice to read that you are finally going to have some RTTY coverage in your publication — it is about time. I first got hooked on that mode many years ago when Wayne Green ran his series of articles in *CQ*.

Now that the *RTTY Journal* is moving back to the West Coast, we could use some coverage for the East and Middle West.

Incidentally, I had always been informed that RATT stood for Radio Amateur Teletype. However, it is no longer used in Navy MARS, although it was ten years ago or so, when I first joined.

Herb Draeger WB5HVE
Mountain Home AR

I'm looking forward to the new column. The timing couldn't be better. I just was handed a Model 15 which is geared for 65 wpm.

I have an SB-303 receiver and an SB-401 exciter. My receiver is already set for FSK of the transmitter via shifting of the vfo in the transceive mode.

So, as you say, John, "Let's get started."

CONTESTS

FOUR LAND QSO PARTY

Starts: 1800 GMT Saturday, September 3;
Ends: 0200 GMT Monday, September 5

Sponsored by the Fourth Call District Amateur Radio Association of the IARS, Inc. The same station may be worked again on each band and/or mode fixed, and repeated again if operated portable or mobile and from each different county.

EXCHANGE:

RS(T), county, and state for 4th call district; state, province, or country for others.

SCORING:

4th call district stations score 1 point for W/VE QSOs and 3 points per DX contact (including KH6 and KL7). Final score is total points times states and provinces; states and provinces count only once, regardless of band/mode. All others score 2 points per QSO and multiply by the number of 4th district states and counties; count each state and county only once.

FREQUENCIES:

CW — 3575, 7060, 14070, 21090, 28090 (±10 kHz); phone — 3940, 7260, 14340, 21360, 28600; Novices — 3710, 7110, 21110, 28110 (±10 kHz).

ENTRIES AND AWARDS:

Certificates to top scorers in each state, province, and country. Second and third place when scores warrant. Other awards to each 4th district county, Novices, SWLs, etc. Logs must be mailed with score within 30 days to Fourth Call District ARA, Attn: Bob Knapp W4OMW/W4NP, 105 Dupont Circle, Greenville NC 27834. Include an SASE for results.

WASHINGTON STATE QSO PARTY

Operating Periods:
0100 to 0700 GMT September 10;
1300 GMT September 10 to 0700 GMT September 11;
1300 GMT September 11 to 0100 GMT September 12

Sponsored by the Boeing Employees' ARC (BEARS), the contest is open to all amateurs. All bands and modes may be used. Stations may be worked once per band and mode, and may be worked again if they are a new multiplier.

EXCHANGE:

WA stations send QSO number, RST, and county; others send QSO number, RST, and state, province, or country.

FREQUENCIES:

CW — 1805, 3560, 7060, 21060, 28160; phone — 1815, 3935, 7260, 14310, 21380, 28660; Novice — 3735, 7125, 21150, 28160.

SCORING:

Score 2 points per QSO. WA stations multiply QSO points by total number of states, provinces, and other countries worked. All others score 2 points per WA QSO and multiply by number of WA counties worked (39 max.). For non-WA stations only, there is an extra multiplier of one for each group of 8 contacts with the same WA county.

Washington county checkoff list for non-Washington State entries: Adams, Asotin, Benton, Chelan, Clallam, Clark, Columbia, Cowlitz, Douglas, Ferry, Franklin, Garfield, Grant, Grays Harbor, Island, Jefferson, King, Kitsap, Kittitas, Klickitat, Lewis, Lincoln, Mason, Okanogan, Pacific, Pend Oreille, Pierce, San Juan, Skagit, Skamania, Snohomish, Spokane, Stevens, Thurston, Wahkiakum, Walla Walla, Whatcom, Whitman, Yakima.

ENTRIES AND AWARDS:

Certificates to high scores in both single and multi-operator classes. Five BEARS awards are also available to anyone working 5 club members. All contest entries will be screened by the contest committee for possible Worked Five BEARS Awards. The Worked 3 BEAR Cubs Award is also available for working 3 Novice members. Logs are available from the contest committee upon request. Logs must show dates/times in GMT, stations worked, exchanges, bands and modes, and scores claimed. Include a check sheet for entries with more than 100 QSOs. Each entry must include a signed statement that the decision of the Contest Committee will be accepted as final. Logs will *not be returned*. Results of the QSO Party will be mailed to all entrants; an SASE is *not* required. Logs and scores must be postmarked no later than October 10th and sent to: Boeing Employees' ARC, c/o Contest Committee, Willis D. Propst K7RS, 18415 38th Ave. S., Seattle WA 98188.

PENNSYLVANIA QSO PARTY

Starts: 1700 GMT Saturday, September 10;
Ends: 2359 GMT Sunday, September 11

Sponsored by the Nittany ARC; all amateurs are invited to participate. PA stations may work both PA and non-PA stations. Each station may be worked once per band and mode.

EXCHANGE:

QSO number, RS(T), county or ARRL section.

FREQUENCIES:

CW — 1810, 3550, 7050, 14050, 21050, 28050; SSB — 1815, 3980, 7280, 14315, 21380, 28560; Novice — 3715, 7160, 21115, 28115.

SCORING:

PA stations score 3 points per out-of-state QSO and 1 point per PA QSO. Multiplier is number of ARRL sections, including EPA and WPA. One additional multiplier may be counted for DX QSO (limit: one). Out-of-state stations score 1 point per PA QSO times the number of PA counties worked (67 max.).

ENTRIES AND AWARDS:

Logs must include dates/times in GMT, stations worked, RST sent/rcvd., band, mode, and number of new section or county as worked (multipliers). Summary sheet required, showing number of QSOs, QSO points, total multiplier, and claimed score. Also, include a checklist of counties worked. Mail logs, summary sheets, check sheets, and any comments by Oct 15th to: Douglas R. Maddox W3HDH, 1187 S. Garner Street, State College PA 16801. SASE appreciated. Certificates to section winners and outstanding PA entries with minimum of 10 QSOs required for awards.

NORTH AMERICAN SPRINT CONTEST

0200 to 0600 GMT Sunday, September 11

Sponsored by the National Contest Journal, this contest is open to all amateurs. Entry classes include: single op (no helpers, one active xmtr, multiple rcvrs, no spotting net assistance); multi-single (multiple operators, one active xmtr, multiple active rcvrs, no spotting net assistance); multi-multi (multiple operators, multiple active xmtrs, one signal per band). All contacts must be made on CW only on any band from 160 to 20 meters. Stations may be worked once per band. North American stations are defined by the rules for CQ WW contests.

EXCHANGE:

You must make sure the entire exchange includes his call, your call, serial number (starting from 001), your nickname, state, province, or country. Example: W6OAT DE WB2GFE NR 27 BOB NJ K.

FREQUENCIES:

1800-1820, 3530-3550, 7030-7050, 14030-14050. Try 160m during the last half hour of the contest.

SPECIAL RULES FOR NA STATIONS:

If a station calling CQ NA is called by another station and makes a valid exchange with him, he cannot call CQ again on that frequency, nor can he solicit contacts by calling QRZ, etc. He must move a minimum of 5 kHz away from the frequency before calling CQ NA again, or he may answer a CQ NA on the frequency and, following a valid exchange, call CQ NA on that frequency.

CLUB COMPETITION:

Club competition is limited to a maximum of 15 operators as a single club entry unit. Clubs with more than 15 members may submit more than one entry unit. In this case, members of each unit must be drawn by lottery from the pool of members who will compete. To qualify as a club entry

CALENDAR

Sept 3-5	Four Land QSO Party
Sept 10-11	Washington State QSO Party
Sept 10-11	Pennsylvania QSO Party
Sept 10-11	ARRL VHF QSO Party
Sept 10-11*	European DX Contest — Phone
Sept 11	North American Sprint Contest
Sept 17-18	Scandinavian Phone Contest
Sept 24-25	Delta QSO Party
Sept 24-25	Scandinavian Phone Contest
Sept 25-26	Fall Classic Radio Exchange
Oct 1	Open CD Party — CW
Oct 1-2	California QSO Party
Oct 1-2	VK/ZL/Oceania — Phone
Oct 8-9	VK/ZL/Oceania — CW
Oct 15-16	Open CD Party — Phone
Oct 15-17	Manitoba QSO Party
Oct 22-23	CQWE Contest
Oct 22-23	CARTG RTTY Sweepstakes
Oct 29-30	CQ WW DX Phone Contest
Nov 5-6	ARRL Sweepstakes — CW
Nov 12-13	IPA Contest
Nov 12-13	European DX Contest — RTTY
Nov 13	OK DX Contest
Nov 19-20	ARRL Sweepstakes — Phone
Nov 19-20	WWDXA International CW Contest
Nov 19-20	All Austria Contest
Nov 26-27	CQ WW DX CW Contest
Dec 3-4	ARRL 160 Meter Contest
Dec 10-11	ARRL 10 Meter Contest

*Described in last issue.

unit, the name and call of each operator in the unit must be registered with the Contest Coordinator (W6OAT) before 6:30 PDT, Sept. 10th. Changes may be made in the unit members up to that deadline. This rule limits multi-multi entries to a maximum of 15 operators if they are a club entry. Multi-multi's, multi-singles, and singles can be combined in a single unit, but the total number of operators cannot exceed 15.

SCORING:

NA stations multiply total valid contacts by the sum of states, VE multipliers, and countries to get final score. Non-NA stations multiply total valid contacts by the sum of states, VE multipliers, and NA countries. KH6 is not counted as a state and is not an NA country. VE multipliers are: maritime (VE1, VO1, VO2, etc.), and each VE call district (VE2 to VE8).

ENTRIES:

Logging is to be done on separate sheets for each band. Regardless of the number of licensed callsigns issued to a given operator entering, one and only one callsign shall be used during the contest period by that operator. Logs should include GMT time as well as complete exchange information.

Entries must be sent to Rusty Epps W6OAT, 35 Belcher Street, San Francisco CA 94114, and be received by Oct. 10th to be eligible for trophies and awards. Each entry should include a summary sheet showing valid contacts by band, total multipliers, total score, name and call of operator(s), station callsign, location, and declaration statement ("I declare, on my honor, that I operated in understanding and compliance with the NCJ Contest rules as well as all regulations for amateur radio in my country, and that my summary and log sheets are correct and true to fact."), followed by the signature(s) of the operators. Also required are a complete, legible log of all contacts (by band, with indication by numbered sequence of each multiplier claimed) and a separate check sheet for each band.

RESULTS

RESULTS OF THE 1977 FLORIDA QSO PARTY

Top 10 FLA Phone Stations		Top 10 FLA CW Stations	
WA4LZR	94,135 points	WA4NFF	27,900 points
WA4UFW	55,057	K4BV	10,560
WB4PQB	34,713	W4OO	10,098

DELTA QSO PARTY

Starts: 1800 GMT September 24;
Ends: 2400 GMT September 25

Sponsored by the Delta Division of the ARRL; all amateurs are invited to participate. No time or power restrictions. Amateurs outside of the Delta Division will attempt to contact as many amateurs inside the Delta Division (consisting of Ark., La., Miss., and Tenn.) as possible. Stations may be worked once per band/mode. Portables/mobiles may be reworked on the same band/mode if they change counties.

EXCHANGE:

QSO number, RST, and QTH — ARRL section for non-Delta Division; county and state for Delta Division.

FREQUENCIES:

CW — 3550, 7050, 14050, 21050, 28050; SSB — 3990, 7290, 14290, 21390, 28590; Novice — 3725, 7125, 21125, 28125.

SCORING:

Delta Divisions take number of QSOs times number of ARRL sections (75 max.). Outside the division, take number of QSOs times number of counties worked (316 max.). DX stations may be worked, but do not count as multipliers.

ENTRIES AND AWARDS:

Logs must include date/time, call, exchange, band, emission, and multiplier. Logs must be postmarked no later than Oct 21st to be eligible for awards. The Delta Achievement Award is issued to all amateurs contacting 5 different stations in each of the 4 states in the Delta Division.

RESULTS

RESULTS OF THE 1977 BARTG RTTY CONTEST

Top 10 Single Operator Stations (107 Entries)

CT1EQ	488,160 points with 336 contacts
9H1EL	409,464 points
I5WT	281,160
I5KPK	270,560
G3YYD	258,560
K5ARH	235,056
SM6GVA	230,838
PJ3AR	229,600
W3FV	219,186
W2NZ	218,988

The top multi-operator entry was from I1PYS, with 388,448 points. W1MX finished third in the multi-op category. The top SWL entry was from Cech Luhos (OK2-5350), with 278,820 points.

Other certificates and plaques for high scores. Logs will be returned if requested. Send logs to Malcolm P. Keown W5RUB, 213 Moonmist, Vicksburg MS 39180.

FALL CLASSIC RADIO EXCHANGE

Starts: 1800 GMT Sunday, September 25;
Ends: 0100 GMT Monday, September 26

Sponsored by the Southeast ARC (K8EMY) of Cleveland, Ohio, the contest is open to all. The object is to restore, operate, and enjoy older equipment with like-minded hams. A "classic radio" is any equipment built since 1945 but at least 10 years old — an advantage, but not required in the exchange.

EXCHANGE:

Name, RST, state, province, or country, receiver and transmitter type (if home brew, send PA tube, e.g., "6L6").

MISCELLANEOUS:

The same station may be worked with different equipment combinations, and on each mode on each band. No AM phone below 21 MHz. CW call is "CQ CX"; phone call is "CQ EXCHANGE". Non-contestants may be worked for credit.

FREQUENCIES:

CW — up 60 kHz from low end of band edges; phone — 3910, 7280, 14280, 21380, 28580; Novice/Tech — 3720, 7120, 21120, 28120.

SCORING (NOTE CHANGES FROM LAST YEAR):

Add the numbers of different transmitters and receivers, states/provinces/countries contacted for each band. Multiply by total number of QSOs. Multiply that total by class multiplier, the total years old of all transmitters and receivers (three QSOs minimum per unit). For transceivers, multiply years old by two.

ENTRIES AND AWARDS:

Awards for highest scores, longest DX, most equipment combinations, oldest equipment, and "unusual achievements." Send logs, comments, pictures, etc., to Stu Stephens K8SJ, 2386 Queenston Road, Cleveland Heights OH 44118. Include an SASE for a copy of the *Classic Radio Newsletter*.

CALIFORNIA QSO PARTY

Starts: 1800 GMT Saturday, October 1;
Ends: 2400 GMT Sunday, October 2

Sponsored by the Northern California Contest Club. Of the 30 hour period, the maximum operating time shall not exceed 24 hours. Times on and off must be clearly marked in the log, and each time off shall not be less than 15 minutes. All amateur bands may be used, and stations may be worked once per band and mode. Mobile or portable CA stations may be worked in each new county on each band and mode. CA stations may work other CA stations.

EXCHANGE:

CA stations send consecutive QSO numbers and county; others send QSO number and state, province, or country.

FREQUENCIES:

CW — 1805, 3560, 7060, 14060, 21060, 28060; SSB — 1815, 3895, 7230, 14280, 21355, 28560; Novice — 3725, 7125, 21125, 28125. Try 10 meters on the hour and 15 meters on the half hour between 1800 and 2200 GMT.

SCORING:

Each QSO counts 2 points. CA stations multiply QSO points by number of states (including CA) plus Canadian districts (8 max.). DX may be worked for QSO points, but does not count for multipliers. Non-CA stations multiply QSO points by number of CA counties worked (58 max.).

ENTRIES AND AWARDS:

Log information should include date/time, band, mode, callsigns worked, and exchanges sent/received. Number each new multiplier as worked. A summary sheet should be included, showing your callsign, name, address, number of QSOs per band, total number of QSOs, total multiplier, claimed score, and indication of whether single or multi-operator entry. Summary sheets are available from the NCCC. Certificates are awarded to the highest scoring station in each CA county, state, province, and country. Portable stations must make 20 QSOs minimum for county certificate. There will be second and third place awards if justified, as well as special high score awards and a club award for highest aggregate score. All entries must be sent to the NCCC, c/o Lew Jenkins N6VV, 1750 Eucalyptus Ct., Concord CA 94521, and must be postmarked not later than Oct. 31st. Please include a large business-size SASE with each entry.

ZONE 29 AWARD

Issued by the West Australian Division of the Wireless Institute of Australia to amateurs and SWLs worldwide for contacts with 25 stations located within zone 29. Contacts may be on any amateur band or mode, but must have been made after January, 1952. The following endorsements are available when the award is issued as confirmation of following special conditions:

(a) All 25 stations on one band only;
(b) All 25 stations on phone (SSB, AM, FM, etc.);
(c) All 25 stations on CW;
(d) All 25 stations on one band and all on phone;
(e) All 25 stations on one band and all on CW;
(f) 25 stations heard by SWL listener, in (a) to (e) above.

Confirmation in writing of all contacts must be submitted to: The Secretary, WIA (WA Division), Box N. 1002, GPO, Perth, W.A. 6001, Australia. Include S1 or 5 IRCs for postage and handling.

Corrections

There is an error in the article "The Morse Clock," July, 1977. The table in Fig. 7, page 57, has an incorrect value. The ROM contents for digit 1 should be "11110", not "10000" as indicated.

John Molnar WA3ETD
Executive Editor

There are several corrections to "Super DVM," starting on page 108 in the August, 1977, issue. The zener diodes in Fig. 4 are incorrectly designated. The two diodes marked "1NT63" should be 6.2 V 1N753 diodes. In Fig. 3, the op amp is shown with incorrect pinouts. The 100 pF capacitor should be connected between pins 8 and 1, not between 8 and 7 as shown. The power should be connected to pin 7. This pin is not numbered in the figure. The photographs in "Super DVM" were taken by Bert Mau.

John Molnar WA3ETD
Executive Editor

There's an error in my article, "Build A Multiplying Prescaler," in the July issue. Fig. 9(b) on p. 136 should show IC2 pins 5 and 8 grounded, as in Fig. 8.

J. H. Everhart K3JE/2
Lancaster PA

The balun transformer illustrated in Fig. 4 of "Satellite Zapper," on page 83 of our May issue, is in error. The RG-58 coax cable indicated should in reality be RG-59 or RG-11 cable. The balun transformer requires 72 Ohm cable to properly match the 300 Ohm twinlead.

John Molnar WA3ETD
Executive Editor

The article "Inside The Bird," by Robert Bloom, July, 1977, made several references to the term THRU-LINE™ on page 44. This term is a registered trademark of Bird Electronic Corporation, Solon, Ohio, and was incorrectly used without the identifying trademark symbol.

There are also three errors in the article: The resistor in Figs. 2 and 3 has to be on opposite sides of the loop, not in the left leg. On page 45, column one, the formula for I_r is missing a minus sign, and in column two, I^2R is printed as "1^2R". The correct formulas are: $I_r = -E_r/Z_0$ and $I^2R = IE$.

John Molnar WA3ETD
Executive Editor

My letter to you dated 19 May concerning the conversion of certain SSB CB rigs to 10 meters contains a rather foolish statement which I wish to correct. I had said that using a 12.6685 MHz crystal in place of the X4 value given in the table would yield six additional frequencies between 28.6 and 28.8 MHz. This is obviously erroneous: The suggested change would indeed produce six frequencies different from the original crystal frequency, but no more of them would be between 28.6 and 28.8 MHz with either crystal. My apologies — this was an admittedly stupid error which I made due to trying to do the math involved in the conversion at 0230 hours.

Those who are involved in the Ten-Ten activities, and have no particular desire to operate in the DSB full carrier mode, may be interested in the following set of crystal frequencies. When substituted for the high oscillator crystals in the Cobra 138A/138, Midland 13-895, or Pace 1000 CB transceivers, they will produce 23 operating frequencies between 28.510 and 28.800 MHz. X1 — 12.5485 MHz; X2 — 12.5585 MHz; X3 — 12.5685 MHz; X4 — 12.5885 MHz.

If you calculate the operating frequencies obtained with the above, you will note that all of them fall on frequencies which are evenly divisible by 10 kHz. Since approximately one third of the existing Ten-Ten local nets meet on frequencies which are not evenly divisible by 10 kHz, you may want to change one or more of the crystal frequencies by a few kHz to accommodate your local net.

I will repeat my earlier caution that the "delta tune" controls on most SSB CB radios swing both the transmit and receive frequencies. This is accomplished in the abovementioned radios by a varactor diode which operates in the high oscillator circuit. My experience has been that the maximum frequency swing with the original components is on the order of one kHz plus and minus. It may be possible to increase this range by using a different varactor, but I don't know of anyone who has tried it.

Finally, a brief comment on WA4MFT's 10 meter bandplan — fooey! As far as I'm concerned, we already have enough bandplans on the VHF and UHF bands without encumbering the HF bands with them. Some cooperation among 10 meter AM ops is indeed necessary, but Ray's plan is just too structured for my taste.

Stan Modjesky WB3CJI
Woodlawn MD

A FAAR-OUT DXpedition

-- airborne VHF and OSCAR!

On Saturday, September 17, 1977, the FAAR-OUT Airborne DXpedition will take to the skies over California and Nevada. FAAR-OUT (*F*ive *A*irborne *A*mateurs *R*eaching *OUT*) will provide a unique opportunity for VHF/UHF/microwave amateur operators to participate in a unique experimental DXpedition. We will fly a 1085 statute mile route over a period of nearly eight hours, operating on 4 bands and using several modes of communications. We will be seeking a maximum number of contacts on all bands and modes, and will be looking for real DX stations, as well.

We expect to make contacts with stations in high locations, with good antennas, and with other airborne stations. For pilots who would like to know our exact flight plan, here 'tis: San Jose V334 Sacramento V6N Reno V105 Las Vegas. Lunch and refuel at Las Vegas, then via V21 Hector VOR, V12 Palmdale, V137 Priest VOR, V485 San Jose. We plan to fly the San Jose to Las Vegas leg between 1600 GMT and 2000 GMT, and the Las Vegas to San Jose return leg between 2100 GMT and 0100 GMT. This timing may vary up to an hour each, or either way, and the exact times will depend on the weather and upon OSCAR orbits. The San Jose-Las Vegas leg will be flown at 11,500 feet, and the return leg will be flown at 12,500 feet.

We will be operating on the following bands and modes: 146.52 MHz FM, 145.1 MHz SSB, 223.50 MHz FM, 432.0 USB, 446.0 FM, 437.25 ATV, OSCAR Mode B, and 1296.010 USB. At present, the inclusion of ATV equipment is contingent on getting the equipment working in time, and the OSCAR shot will be made if mode, orbit, and antenna installations on the aircraft permit.

The following operators will be operating the following bands, etc.: 146.52 MHz FM – Dave WB6KHP, 40 Watts ERP; 145.1 MHz SSB – Ray WA6VAB, 40 Watts PEP; 223.50 MHz FM – Brad WA6REE, 10 Watts ERP; 437.25 ATV (if aboard) – Ray WA6VAB, 40 Watts peak video; 432.0 USB – Paul WA6UAM, 40 Watts PEP; 446.0 FM – Alan WA6YOB, 10 Watts ERP; 1296.010 USB – Paul WA6UAM, power not specified; OSCAR Mode B – Paul WA6UAM, 40 Watts PEP.

In addition, if other airborne amateurs wish to contact us and find the QRM a bit much, call Cessna N1522Q on 122.90. We'll fit you in. Please call the operator listed above for the particular band/mode you will be using. We are not planning to use a single call for the DXpedition.

In order to provide an opportunity for as many amateurs as possible to contact us, we request that when you call us, give your callsign and wait for an acknowledgement. Keep trying. There will be QRM and our own self-generated intermod for us to contend with, so if we seem a bit abrupt in acknowledging your contact, please be patient. Be sure to log it, too, and we will QSL 100% of verified contacts with a specially-printed photo QSL card for the expedition. We will also QSL all SWL reports that indicate that you have copied our transmissions.

If conditions permit, we are also going to try some propagation experiments within the California coastal duct. If the duct appears to be forming, or present during the latter part of our flight, we will be flying up and down inside it, in an effort to discover what atmospheric phenomena may be related to various modes of propagation within it. If we locate the duct, we will be operating primarily on 145.1 and 432.0 SSB.

Anyone wishing to schedule a contact or contacts with us can send a note requesting the desired schedule time and frequency(ies) to: Alan Christian WA6YOB, PO Box 5314, San Jose CA 95150. We will reply by mail and will make every effort to keep the schedule.

The SSB and ATV antennas will be horizontally polarized, and the FM antennas will be vertically polarized in an effort to maximize contacts.

If inclement weather on the West Coast causes postponement of the flight on the 17th, we will fly the expedition one week later on September 24.

If you have any questions about the DXpedition, please feel free to write. We would appreciate an enclosed SASE, but we will answer all queries. It seems advisable for stations near our proposed coverage limits to write and schedule their contacts in advance. ■

So You Want To Get Into RTTY?

-- "Call For Papers" winner

So you want to get into radioteletype? Congratulations, you made the right decision. Radioteletype (abbreviated RTTY) is the most interesting, fascinating and rewarding mode of communication around today.

The burgeoning of integrated circuits over the last decade and the rapid decrease in the cost of these circuits have made it easier than ever before to get into RTTY at a minimum cost. It is this proliferation that has also aided the development of RTTY systems that were heretofore impossible or impractical. For example, how would you like to be able to turn your friend's teleprinter on and leave a message for him when he gets home? You can do it; it's called a selective calling system. Or how would you like to turn on a transmitter thousands of miles away to get an idea of current propagation conditions? No problem. If the other station has an answer-back system, all you need do is type the station's access code. The transmitter is then automatically turned on and a short message is broadcast. If you are of an artistic bent, exchanging RTTY pictures should fulfill your desires. If you enjoy music, composing songs to be played on the teleprinter will prove fascinating. If building is your bag, you have come to the right place. While commercial equipment is available, building your own equipment should prove rewarding, not to mention the pecuniary savings. If contests are your main interest, RTTY has many throughout the year. You say collecting award certificates is your thing? Then try working all states or all continents on RTTY for a challenge. If you like to rag chew, you have come to the right place.

Photo 1. The author and friends. The basic RTTY equipment includes a Model 15 teleprinter, an ST-6 demodulator, and an AFSK modulator. The amenities include an electronic keyboard; a CRT RTTY tuning indicator; a UT-4 for signal regeneration and electronic speed conversion; a digital date, time, and message generator for the Selcal and W-R-U system; and a cassette tape recorder for storing and transmitting data. (Photo by Anthony R. Donaldson.)

RTTY is a very relaxing way to communicate. Since the conversation is printed on paper, you can go get that cup of coffee or glass of soda pop while the other fellow is talking without missing any of the conversation. It is also possible to start answering the other fellow while he is still talking by punching your message into paper tape. When the other fellow is finished transmitting, you can send your prepared message back.

If you want to keep informed on different aspects of ham radio, W1AW broadcasts RTTY bulletins daily. Information on OSCAR crossings, propagation, and general comments about ham radio are given. You say you like to keep abreast of the news and weather? No problem. Many commercial stations such as the Associated Press broadcast news bulletins throughout the day. Other commercial stations broadcast weather conditions. This type of information could be most useful during

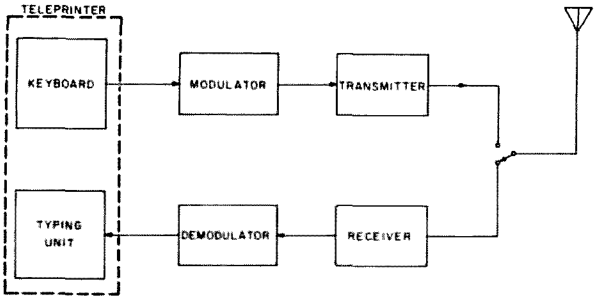

Fig. 1. Typical RTTY station block diagram.

the tornado or hurricane season.

If you are technically oriented, the flexibility of RTTY should interest you. Many amateurs are connecting microcomputers to their stations. With one of these, you are only limited by your imagination. You say you don't like the dampened roar of a teleprinter? Then an elegant video display is just what the doctor ordered. If any of these facets of RTTY intrigues you, then read on, and welcome to the wonderful world of RTTY.

While the history of teleprinters goes back to as early as 1906, when the first American teletypewriter was invented, amateur use of teletypewriters is relatively new. Amateurs were involved in radioteletype as early as 1946. But it was not until 1953, when the FCC removed certain restrictions on amateur radioteletype, that the field of amateur RTTY really began to grow.

The amenities of RTTY are indeed myriad, but let's get down to basics. There are actually only three components necessary to get a RTTY station on the air – a teleprinter, a modulator, and a demodulator. Fig. 1 shows these three basic components and their interconnection in a typical RTTY station.

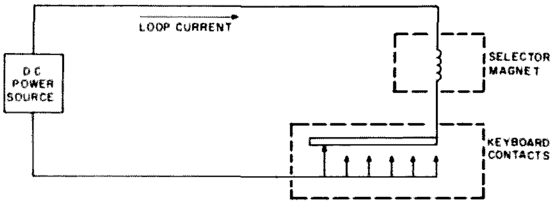

Fig. 2. The Local loop.

PART I
THE BASICS

The Teleprinter

Before getting involved in the technical aspects of teleprinters, a clarification of the word teleprinter is in order. A teleprinter is often wrongly referred to as a "Teletype." Teletype is a registered trademark of the Teletype Corporation. As such, it should always be capitalized and used as an adjective rather than a noun. The name Teletype has come to be used erroneously due to the popularity of the Teletype Corporation products. There are, however, other manufacturers of teleprinters including Kleinschmidt, Lorenz, Mite, and ITT Creed. Therefore, to be correct, I will use the word teleprinter to describe this family of machines.

At the heart of every amateur RTTY station is the teleprinter. The teleprinter is quite similar to a typewriter.

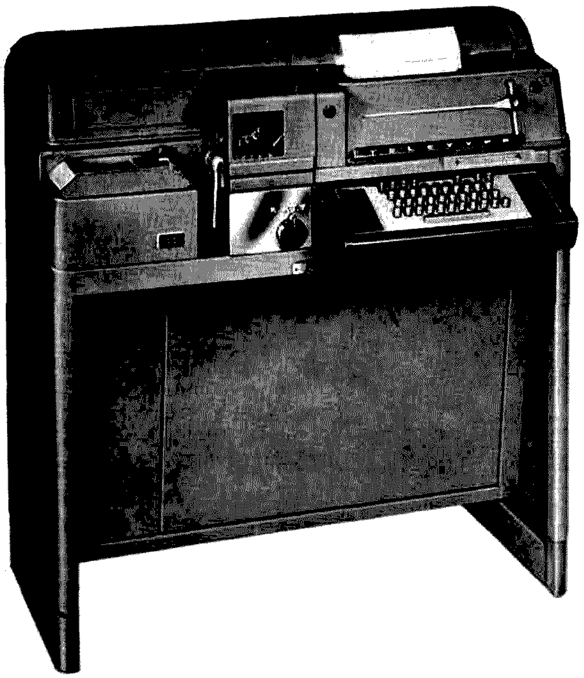

Photo 2. The Teletype Model 28 ASR shown here is a highly respected and sought-after machine. The unit includes a keyboard, a page printer, tape reader, tape punch, and a stunt box for adding special control functions. The Model 28 is built for heavy duty, 24 hour per day operation and easily operates at 100 wpm. Unlike the Model 15, the Model 28 is still manufactured by the Teletype Corporation. (Photo courtesy of the Teletype Corporation.)

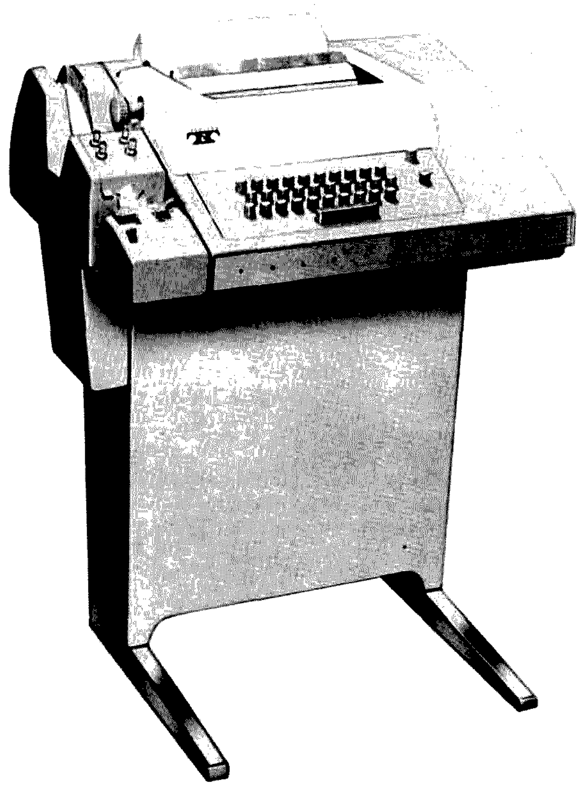

Photo 3. The Model 32 ASR, shown here, is the newest model teleprinter using the Baudot code manufactured by the Teletype Corporation. The machine includes a paper tape reader and punch shown on the upper left side in the photo. (Photo courtesy of the Teletype Corporation.)

Table 1. The Baudot code. M = mark, S = space.

However, in a typewriter there is a mechanical linkage between the key the typist depresses and the arm that comes up and strikes the paper. This is not the case in the teleprinter. The teleprinter consists of two virtually separate units – the typing unit, and the keyboard. When one depresses a character on the keyboard, the keyboard encodes the character as a stream of pulses. The exact coding will be discussed later in greater detail, but at this time it should be noted that each character has a particular code much like the Morse code.

The purpose of the typing unit is to convert the stream of pulses back into a mechanical motion. Typically, the keyboard is also wired to the typing unit so that in addition to sending pulses to another machine, the pulses are received and printed locally.

Fig. 2 shows what is referred to as a local loop. With this circuit configuration, it is possible to type on the keyboard and obtain local copy. Current is flowing in the circuit until broken by the operation of the keyboard. The selector magnet senses the current pulses and prints the requested character.

The condition in which current is flowing in the loop is referred to as the "mark" state. The "space" state is characterized by the absence of current flowing in the loop. With these marks and spaces (current and no current), it is possible to make a code in which a particular combination of marks and spaces represents a particular character. We will discuss this code in greater detail later. The important concept to grasp at this point is that the keyboard and the typing unit are separate and not mechanically attached. In fact, some teleprinters do not have a keyboard at all, such as the Model 28RO. The RO indicates Receive Only. These machines are used where only one-way communication is desired, such as in a commercial newsroom.

While new teleprinters are available from the Teletype Corporation, the price is rather high for the average amateur. For this reason, most amateurs use teleprinters that have been retired from commercial use. A teleprinter may be obtained for as little as $30. Hamfests or advertisements in the amateur radio magazines are good sources for machines.

There are several models of teleprinters that are currently used in amateur applications. However, Models 15 and 28 are the most popular. These models are called page printers. This means the message is printed on a continuous roll of paper rather than a narrow paper strip. The paper tape printer is virtually gone from amateur use.

The Code

Before we get into the two remaining basic units of the RTTY station, the modulator and the demodulator, we must discuss the code used for radioteletype communication.

The code used by the teleprinter is similar in nature to the Morse code. However, where the Morse code uses dots and dashes, the teleprinter code uses marks and spaces. One important difference between the teleprinter code and the Morse code is the length of each basic element or bit of information. For example, the length of a dot or dash is determined exclusively by the operator.

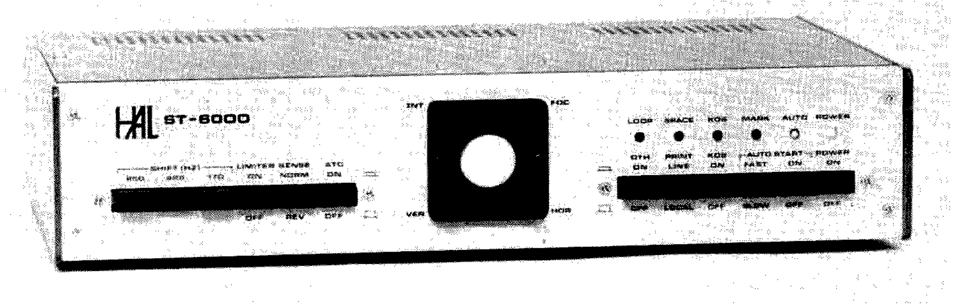

Photo 4. The Hal Communications Corporation is the most popular manufacturer of amateur RTTY equipment. Shown here is the ST-6000. Other demodulators manufactured by Hal include the ST-5000, the ST-6, and the ST-5. Of particular note is that most of the Hal products can be purchased already assembled or in kit form, or, for those with a well-stocked junk box, individual components such as printed circuit boards are available. For more information write Hal Communications Corporation, Box 365, Urbana, Illinois 61801 or call 217-367-7373. (Photo courtesy of Hal Communications Corporation.)

It would be difficult to design equipment that would have to copy correctly at all typing speeds. Therefore, a special teleprinter code, referred to as the Baudot code, is used. This code was designed so that each character contains the same number of elements or bits, and each element is of a fixed duration. One other important characteristic is required of our teleprinter code. When transmitting the code, the receiving teleprinter must be synchronized with the transmitting teleprinter, even though they may be thousands of miles apart. To accomplish this end, a start pulse is added at the beginning of the character, and a stop pulse is added at the end. These pulses are used to insure synchronization of the machines.

Table 1 shows the Baudot code that is used by teleprinters to communicate. All elements of the code are 22 ms (22/1000 seconds) except the stop pulse, which is 31 ms. Fig. 3 represents graphically a teleprinter character. The entire 7 bit word for this character may be written as SSMSMSM. Since the first and last bits are the start and stop bits respectively, the character is reduced to the following 5 bit code, SMSMS. Referring to Table 1, we see the character is the letter "R", or the number "4". Why are there two possibilities you ask? For those of a mathmatical bent, you will notice with a 5 bit code that the maximum number of combinations is 32 (2^5=2 x 2 x 2 x 2 x 2=32). The alphabet and ten digits require 36 (26+10) combinations by themselves, and we still haven't allowed for punctuation and other special functions. To obviate this problem, the teleprinter is equipped with a lower and upper case character set. This is analogous to the upper and lower case of a modern electric typewriter. However, where the typewriter uses "shift" and "unshift" to control the case, the teleprinter uses the "figures" and "letters" command. The upper case is attained by depressing the figures key. The teleprinter moves to the lower case when the letters key is depressed. Going back to our example, if the teleprinter is in the lower case (letters), it will print the letter "R". If a figures key has been depressed previously, the teleprinter will be in the upper case (figures) and print the number "4".

Since each character is of a finite duration, there must be an upper limit to the number of words that can be printed in one minute. Adding the duration of the 7 elements of the code, we arrive at a total time of 163 ms for each character (see Fig. 3). Since each character is 163 ms, the number of characters that can be printed in one minute is 368 (60 seconds/.163 seconds). One word is typically considered to be 5 letters plus 1 space. Thus, the number of words per minute is equal to 61.3 (368/6). This is then rounded off to 60. It would be nice to use machines that operate at higher speeds, but one should remember that teleprinters use mechanical parts that are limited to relatively slow speeds. Video display units are obviously not mechanical and hence are not limited to such low speeds. Speeds of several thousand words per minute are not uncommon. The 163 ms character length sets the upper typing limit at 60 wpm (actually 61.3). Since few amateurs are speed typists, this does not usually limit one's typing speed. While it is true that other speeds are used, such as 67, 75, and 100 wpm, amateurs use 60 wpm almost exclusively.

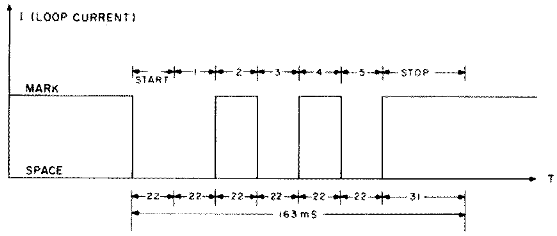

Fig. 3. Graphic representation of the letter "R" or the number "4".

It is important to note that each and every character is 163 ms no matter who is typing or how fast. Contrasting this with CW, even if all operators sent CW at a specific speed, each character is of a different duration. This is a characteristic inherent in the Morse code.

We now know the code that we must use to talk to the teleprinter. Our next task is to put these marks and spaces in a form that can be transmitted over the air. This is the purpose of the modulator.

The Modulator

Modulation refers to the process of transmitting the RTTY signal. Let's return once again to our analogy between CW and RTTY. CW is transmitted by opening and closing a telegraph key. Since a telegraph key is nothing more than a switch, and a teleprinter's keyboard is also a switch, why don't we substitute the keyboard contacts for the telegraph key? With this technique, the mark may be thought of as the transmitter's "on" condition, and the space the transmitter's "off" condition. This is called make-and-break keying and is sometimes used. However, a problem arises using this method. It occurs while the transmitter is off. Suppose a static crash occurs during the space condition (transmitter off); chances are the static crash may be misconstrued by the equipment as a mark, when it is really a space. The net outcome under this method is poor reliability, and thus a wrong character may be printed. We don't have this problem with CW because the incredible machine, the brain, can discriminate between a static crash and a signal.

So now what do we do? The answer is use frequency shift keying (FSK). With this method, the transmitter is on during both the mark and space states. If the transmitter

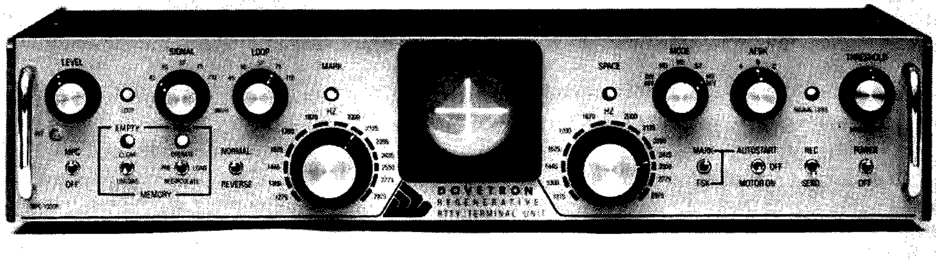

Photo 5. The Dovetron MPC-1000R is the Rolls Royce of terminal units. Some of the special features of the unit are electronic speed conversion, signal regeneration, a character memory up to 200 characters, error correction to erase misspelled words, Tee Dee inhibit, and variable character rate. Front panel controls permit "signal" and "loop" speed selections of 60, 67, 75, 100 wpm Baudot and 110 baud ASCII. (Photo courtesy of Dovetron.)

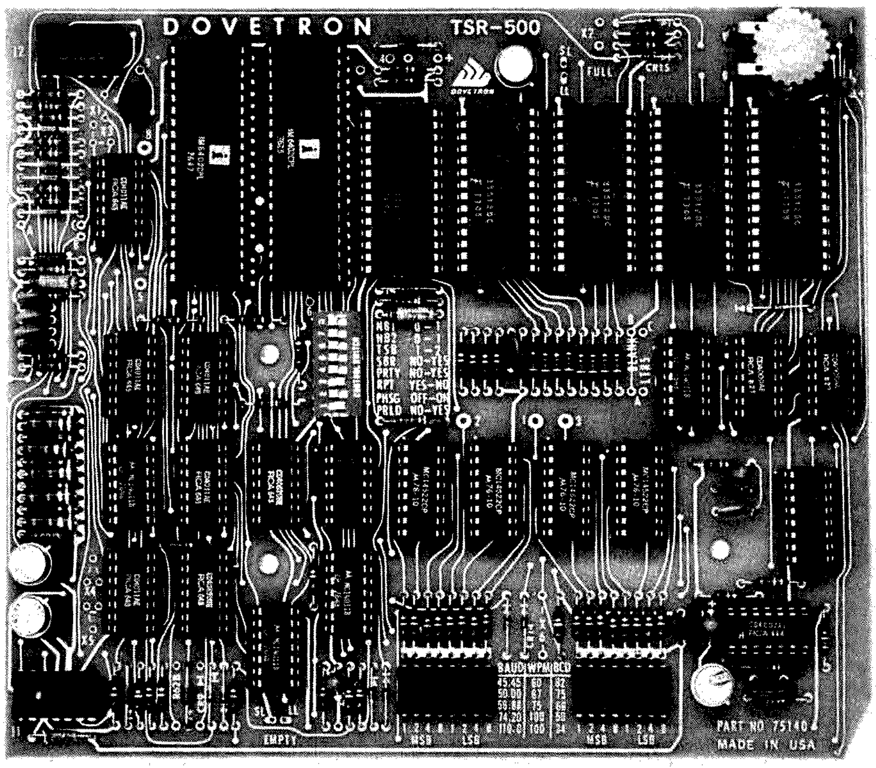

Photo 6. The TSR-500 is at the heart of all the special features of the Dovetron MPC-1000R and may be purchased separately. The error correction circuit allows one to erase the last word put in the memory by depressing a "blank" key. Information on this and other Dovetron products may be obtained from Dovetron, 627 Fremont Ave., South Pasadena, California 91030 or phone 213-682-3705. (Photo courtesy of Dovetron.)

is on during both states, how do we differentiate between the two? Simple, we let the transmitter transmit one frequency during the mark condition and transmit another frequency during the space condition. Thus, we are shifting between two frequencies, and hence the name, frequency shift keying. The difference between the two frequencies is referred to as the shift. While amateurs are allowed to transmit RTTY using any shift less than 900 Hz, the amateur fraternity has settled down to two standards, 170 and 850 Hz shifts. The 170 Hz shift is used almost exclusively on the low bands, while 850 Hz shift is typically used on the VHF bands.

Two methods are used to shift the transmitter's frequency – carrier frequency shift keying (FSK), and audio frequency shift keying (AFSK). With the first technique, the carrier frequency is shifted by placing a capacitor across the transmitter's oscillator tank circuit. This capacitor is connected by the contacts of the keyboard. With the capacitor disconnected, the transmitter is transmitting a mark signal. When the capacitor is connected by depressing a key on the keyboard, the transmitter's frequency is lowered, and this represents the space condition. Typically, the keyboard is buffered from the tank circuit because the keyboard's contacts cannot efficiently control these radio frequency signals, but the idea of connecting a small capacitor for space and disconnecting it for mark remains unchanged.

With the second method, audio frequency shift keying, audio tones are generated and fed directly into the microphone jack of the transmitter. For narrow shift, the AFSK unit generates 2125 and 2295 Hz signals (2295 - 2125 = 170 Hz shift). The 2125 Hz signal denotes the mark signal and the 2295 Hz signal represents the space signal. When the keyboard contacts are closed, a 2125 Hz signal is fed into the microphone jack. The 2295 Hz signal is generated when the contacts are open. Note that with this method, the space frequency is higher than the mark frequency. When using carrier FSK, the opposite is true; the mark frequency is higher than the space frequency. This apparent contradiction can be explained by noting that the heterodyne system of generating a lower sideband signal has the effect of flipping the frequencies over. Therefore, the final space frequency generated by the transmitter is indeed lower than the mark frequency when using AFSK as it is when FSK is used.

The AFSK method of generating a RTTY signal requires a stable audio generator. Its main advantage lies in the ease of interfacing the keyboard with the transmitter. One need simply plug the output of the generator directly into the microphone jack of the transmitter.

The Demodulator

At the receiving end, our job is to decipher the tones and reconstruct the information in a form the teleprinter can handle. There are basically two methods that are used to differentiate between the two tones. The old technique, and still the most widely used, involves demodulation via two separate resonant LC (inductor and capacitor) circuits. In the case of 170 Hz shift, one LC resonant circuit is tuned to pass the 2125 Hz mark signal, and the other is tuned to pass the 2295 Hz space signal. These filter circuits, called discriminators, pass only their respective tones, mark or space, and drastically attenuate all other frequencies. Fig. 4 shows a simplified diagram of this type of demodulator. After the two tones have been segregated through the filtering process, they are fed to a stage called a slicer, which drives the keying transistor. When a mark signal is received, the slicer turns the transistor on, and we have a closed loop. With a space signal received, the slicer turns the keying transistor off, and we have an open loop. Thus the keying transistor acts as a switch. However, more to the point, it is simulating the keyboard switch contacts of the station transmitting.

A modernization of this method employs active filters to replace the passive LC filters. The main advantage of this technique comes from the fact that fairly large inductors (typically 88 mH) are not required. Tuning the

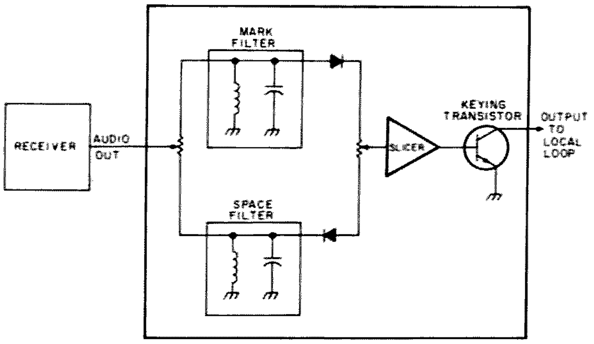

Fig. 4. Simplified circuit diagram of a RTTY demodulator using passive filters.

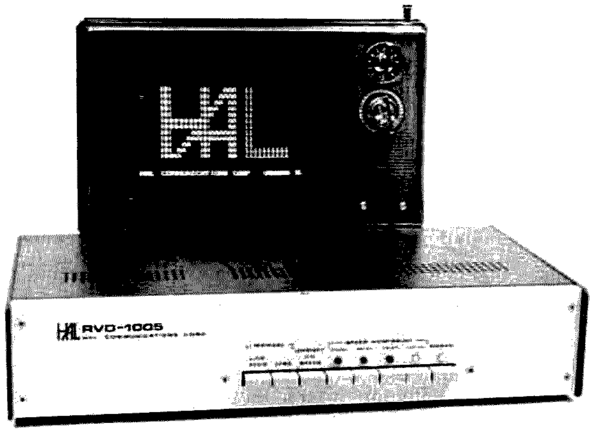

Photo 7. The RVD-1005 visual display unit is the modern answer to the teleprinter. The unit accepts demodulated Baudot signals at 60, 66, 75, and 100 wpm and displays the information on 25 lines with 40 characters per line. (Photo courtesy of Hal Communications Corporation.)

active filters for the exact frequency during calibration is also simpler, since it typically requires an adjustment of a resistor rather than the trial and error technique used in trimming an LC filter to the exact frequency.

The second method that is used to demodulate a RTTY signal uses a phase locked loop (PLL) integrated circuit. Despite its inferiority to the method described above, it is cheap and easy to build. As such, it makes a great demodulator to build to get on the air in a hurry.

PART 2
THE AMENITIES

As previously stated, all that one needs to get a RTTY station on the air is a teleprinter, a modulator, and a demodulator. However, several accessories may be added to a station to really increase the joy of RTTY and operating ease. Amenities available to the RTTY aficionado include an electronic keyboard, a vidio display, tape distributor, tape reperforator, magnetic tape recorder, a CRT RTTY tuning indicator, a Selcal, and a W-R-U answer-back system.

The Electronic Keyboard

Typing on a typical teleprinter keyboard will require some practice and patience, especially if you are accustomed to typing on a modern electric typewriter.

Refering back to Table 1, you can see that the alphabet is printed if the typing unit is in the lower case, and punctuations and numbers are printed if the typing unit is in the upper case. Thus, typing a station call or an address, which contains both numbers and letters, would require extra operations to put the teleprinter into the upper or lower case as desired. An electronic keyboard, designed for the Baudot code, automatically inserts upper and lower case commands to insure the proper character is printed without the operator directly requesting the upper or lower case.

An electronic keyboard has other, more subtle, advantages. In addition to being attractive and quiet, the action of the keys is much smoother than a conventional teleprinter keyboard. These features decrease operator fatigue and increase the ease of operation.

The Video Display

For those who don't like the noise and maintenance of a teleprinter, state of the art technology has made video displays possible. An old black and white TV, coupled with a video display interface module, makes an attractive display.

Two notes of caution. Except for the Hal Corporation unit (see Photo 7), these video display units require a special code called ASCII. ASCII is the acronym for USA Standard Code for Information Interchange. Therefore a unit capable of translating the Baudot code to ASCII is required.

The second shortcoming of a video display deals with the maximum amount of information that can be displayed on the screen. While the format of characters on the screen varies from manufacturer to manufacturer, 1000 characters is typical. This 1000 characters may seem like a lot, but it really isn't. A typical QSO consists of several thousand characters. This means that you cannot look back at the content of a previous transmission or leave the ham shack for more than a few minutes. Both are only slight disadvantages, but, nonetheless, something to consider before purchasing a video display.

The Reperforator

If one wished to record a message to be played back at some later date, he would use a reperforator. The reperforator records a message by punching holes in a narrow strip of paper tape. Messages may be recorded either locally, by typing on the local keyboard, or straight off the air. The Teletype Corporation Model 14RO is a reperforator typically used by amateurs. Of particular importance is that once the paper tape has been made, it may be transmitted at full machine speed (60 wpm), thus expediting the transmission of information. A tape reperforator is used most often by amateurs to make and record RTTY pictures. More on this exciting facet of RTTY later.

The Tape Distributor

The tape distributor is used to read the punched paper tape made on the tape reperforator. The unit translates the holes in the tape into pulses so that they may be printed locally or sent to another station. The Teletype Corporation Model 14TD is a popular tape distributor used extensively on the ham bands.

The Magnetic Tape Recorder

Since the RTTY signals sent to the demodulator are in the audio range (2125 and 2295 Hz), why not record the information on a magnetic tape rather than on paper tape? After all, a cassette player is quieter, cheaper, and more convenient than a mechanical paper tape reperforator. The answer is that we can do just that. In fact, this technique is used extensively by computer hobbyists to record data. However, some problems can arise. For example, when using a narrow shift (170 Hz), this method becomes very sensitive to fluctuations in

Photo 8. Shown here is a small sampling of some of the RTTY pictures that are exchanged on the ham bands. The small uncomplicated pictures require approximately 10 minutes to reproduce at 60 wpm, while some of the large pictures with overlining can require an hour or more. The RTTY Journal *sponsors an annual RTTY art contest for those interested in this facet of RTTY. The pictures were stored on the cassettes shown in the photo. (Photo by Anthony R. Donaldson.)*

the tape speed. The mark and space tones will change frequency as the tape player changes speed. This problem can be remedied by using a high quality tape player with a low wow and flutter specification. There is still one additional complication, though. It would be difficult to find two machines that turn at exactly the same speed. Therefore, the cassettes could not be interchanged between machines. Both problems are solved by using a wider shift (850 Hz). For a mark tone of 2125 Hz to be misconstrued as a space tone of 2975 Hz, the tape player would have to be in very poor shape indeed. Photo 8 shows several RTTY pictures, all of which have been recorded on the cassette tapes shown.

The CRT Tuning Indicator

Several methods for tuning in a RTTY signal have been tried over the years. However, one of the oldest, and perhaps the best, makes use of a cathode ray tube (CRT). The mark and space signals are depicted on the screen of a small CRT (see Photos 4 and 5). The mark is typically a line displayed horizontally, and the space signal is a line shown vertically. With such a unit, the operator tunes the receiver until the horizontal and vertical lines are of maximum length.

The Selcal

The station equipped with a selective calling (Selcal) system can be turned on and off by typing a predetermined access code. While a station may be programmed for any access code, the standard has become the use of the last three letters of the station's call. For example, if your friend's call were W9IUV, typing the last three characters of his call, IUV, at your station would turn on the teleprinter at the station of W9IUV. You can now leave a message. When you are finished, typing four Ns will shut your friend's teleprinter off. The four Ns at the end of the message are a universally accepted shutdown code. Such a system is a great way to keep in touch with friends. Of particular importance is that there is no need for a person to be on the premises. Therefore, the equipment may be left running continuously. I still get a kick out of getting home to a few notes sent by friends. The distinct advantage of this system is that only notes addressed to you are received. In an all-call system, you would receive everyone's notes.

The W-R-U

A W-R-U (who are you) answer-back system is one step beyond a Selcal system. Leaving a note for a friend can be a hit or miss affair unless you are sure his equipment is on. A W-R-U system allows one to ascertain just that. By typing a predetermined access code, one can in essence interrogate the condition of the equipment. Adding the three characters figures, blank, and H after the last three letters of the station's call has become the customary code used to gain access to the equipment. For example, suppose you want to leave a note for W9YPS, but you are not sure if his equipment is up and running. To ascertain the condition of the equipment, you would type the six characters Y, P, S, figures, blank, H. Typically, the message sent after the W-R-U is tripped has been punched on paper tape and is played back on a tape distributor. Having tripped the W-R-U and, thus, confirmed the status of the equipment, you can now proceed as with a Selcal system and leave a note with the assurance the note has been received.

PART 3
SOME UNIQUE ASPECTS OF RTTY

For those of you who are connoisseurs of art, you should enjoy designing, making, receiving, and sending RTTY pictures. The number and kinds are truly prodigious, ranging from angels to nudes. Making a RTTY picture requires a reperforator (paper tape puncher) and a tape distributor (paper tape reader). For those wishing more information on this fascinating aspect of amateur RTTY, consult any of the RTTY handbooks listed in the annotated bibliography.

RTTY Music

I got home late one night during the Christmas season and thought I would listen to a RTTY QSO or two before retiring. Instead of hearing the customary clatter of old faithful (my Model 15), my ears were treated to a chorus of Jingle Bells followed by Noel and other Christmas favorites. This aspect of RTTY makes use of a tape distributor and tape reperforator. Instead of printing a character, the bell of the teleprinter is actuated in time to the melody.

Conclusion

It has been the purpose of this article to give the reader

an introduction to the fascinating world of RTTY and to whet his appitite. For those wishing to pursue this mode of communication further, I have accumulated an annotated bibliography listing books and articles to read for further information on this subject. Good luck and MMSMM MMMSS MSSSS. ■

ANNOTATED BIBLIOGRAPHY

Periodicals and Books Devoted to Radioteletype

American Radio Relay League. *Specialized Communications Techniques for the Radio Amateur.* Newington, Conn., The American Radio Relay League, 1975.

Only a portion of this book is devoted to radioteletype. Other topics include slow scan television, facsimile, and space communication. However, the approximately 70 pages that are devoted to radioteletype are well filled with useful information. I recommend this book highly.

RTTY Journal. *Beginners RTTY Handbook.* RTTY Journal, 1975.

If you want the most for the least, this is it. As the title indicates, the handbook is designed specifically for the beginner. I find it an excellent reference book and recommend it highly. Send $2.50 to RTTY Journal, PO Box RY, Cardiff-by-the-Sea CA 92007.

RTTY Journal

This short but useful periodical is devoted exclusively to

GLOSSARY

AFSK — Abbreviation for audio frequency shift keying. With this method of modulation, two tones (mark = 2125 Hz, space = 2295 Hz) are fed directly into the microphone jack of the transmitter.

Answer-Back (W-R-U) System — A system capable of being remotely controlled by another station. When tripped by a unique access code, a short predetermined message is broadcast.

Autostart (All-Call) System — An autostart circuit may be thought of as a squelch circuit. If an authentic RTTY signal is detected, the teleprinter motor is turned on and the message is printed. Unlike a selective calling system that turns the teleprinter on only when a particular access code is received, autostart circuits act as an all-call system and, thus, print any RTTY signal. The cessation of the RTTY signal causes the teleprinter motor to turn off.

ASCII — Acronym for the USA Standard Code for Information Interchange. At present, this code cannot be used on the amateur bands without special FCC permission. Unlike the 5 level Baudot code, this is a 7 level code used extensively in the electronics industry.

Baud — The basic unit of speed derived from the duration of the shortest code element. For 60 wpm operation, the baud rate is 45.45 (1/22 ms).

Baudot — The code used by amateur RTTY stations to exchange information. It is a 5 level code plus one start and one stop bit.

Discriminator — A discriminator, as used in RTTY circuits, consists of a filter, either passive or active, to pass one frequency and discriminate against all others.

FIFO — Acronym for first-in/first-out. A special integrated circuit memory device that will accept parallel data and retransmit it on a first-in, first-out basis.

FSK — Abbreviation for frequency shift keying. With this method of modulation, the frequency of the transmitter's crystal or vfo is shifted.

KB — Abbreviation for keyboard.

KOX — Acronym for keyboard operated transmission. A station equipped with a KOX system can turn on the transmitter and turn off the receiver simply by typing on the station's keyboard. When the operator ceases typing, the transmitter automatically turns off, and the receiver turns on after some preset delay.

Local Loop — The circuit containing a power source, the selector magnets and a keyboard. This connection allows local copy on the teleprinter (see Fig. 2).

Mark — In RTTY applications, the mark is one of two states. The mark condition is characterized by a closed circuit. The space, the other state, is characterized by an open circuit condition.

Modem — Acronym for modulator, demodulator. A modem is typically used in a system where tones are transmitted and received over telephone lines. It may be thought of as the equivalent to a RTTY station's terminal unit.

PLL — Abbreviation for a phase locked loop. A PLL integrated circuit can be employed in a RTTY demodulator to discriminate between the mark and space tones.

RTTY — Abbreviation for radioteletype. Often pronounced "ritty."

Selcal — Acronym for selective calling system. This system allows the teleprinter to be remotely controlled by a unique code.

Selector Magnet — An electromagnet that senses current flowing in the local loop and picks a character to be printed in response to the current pulses.

Shift — The difference between the mark and space frequencies. For example, if the mark frequency is 2125 Hz and the space frequency is 2295 Hz, the difference of 170 Hz is referred to as the shift. The 170 and 850 Hz shifts have become two widely used standards.

Space — One of two states describing the condition of a teleprinter's loop. The space is characterized by an open loop condition. The mark state indicates a closed loop.

Stunt Box — A mechanical unit that allows the operator to add control features to the teleprinter; for example, an automatic "non-overline" control which prevents printing over a message already typed. Controlling a remote device is another use for the stunt box.

Tape Distributor — A machine that reads prerecorded paper tape.

Tape Reperforator — A device that records data by punching holes in a paper tape.

TU — Abbreviation for terminal unit. This is the RTTY equivalent to a modem. It contains a modulator, demodulator, and loop power supply.

UART — Acronym for universal asynchronous receiver transmitter. A sophisticated integrated circuit that accepts serial data and retransmits it as parallel data and vice versa.

W-R-U — Abbreviation for who are you. See Answer-Back system.

amateur radioteletype. To subscribe send $3.50 to RTTY Journal, P.O. Box RY, Cardiff-by-the-Sea CA 92007. Price differs outside the U.S., Canada, and Mexico.

73 RTTY Handbook

There are two RTTY handbooks, both of which are, or have been, distributed by *73*. The old RTTY handbook, while probably a fine book several years ago, is currently outdated. Being aware of this shortcoming, *73* has recently released a new handbook called, appropriately enough, *The New RTTY Handbook*.

Teleprinters

McNatt, M.S. "A Guide to Baudot Machines: Part 1, Description of Available Devices," *Byte*, April 1977, p. 12.

An excellent, interesting, and succinct article describing many of the Teletype Corporation machines (i.e., Models 11, 12, 14, 15, 19, 20, 26, 28, 29, 31, 32, 33, 35, 37, 38, and 40). On page 158 of this article is a list of sources for Baudot equipment.

Modulators

Roos, J.C. "Universal AFSK Generator," *73*, July 1974, p. 37.

This article describes a RTTY modulator using the AFSK method of modulation. The unit is somewhat advanced for the beginner, but it does a very nice job. This is the modulator I have been using for several years, and I can speak highly of its effectiveness and reliability.

Demodulators

Grossman, B., and John S. Reid. "Building the Safari RTTY Terminal," *73*, August 1976, p. 122.

Unlike most demodulators that use passive filters (inductor and capacitor) to discriminate between the mark and space frequencies, this unit uses active filters. Inherent in active filters is their ease of calibration. A resistor is used to trim the filter to the exact frequency, rather than the iterative method used in LC filters.

Hoff, I. M. "The Mainline ST-6 RTTY Demodulator," *Ham Radio*, January 1971, p. 6.

The author, Irvin Hoff, has probably done more for RTTY within the last 15 years than any other RTTY aficionado. He is responsible for many demodulators, of which this article describes the most advanced. This unit has become a standard of excellence in the RTTY community. For the amateur who is earnest about RTTY, this is the demodulator to get.

Joffe, A.S. "Ridiculously Simple RTTY System," *73*, September 1976, p. 70. For those who want to get on RTTY in a hurry, this is the article you want. The demodulator, while lacking sophistication, works, and you can't argue with success.

Stinnette, N. "Phase Locked Loop RTTY Terminal Unit," *Ham Radio*, February 1975, p. 36.

This article describes a simple demodulator using the phase locked loop principle. This is probably the best demodulator for the neophyte to RTTY since it is cheap and simple.

Selcal, Answer-Back, and Related Equipment

Kelly, B. "Monitor Receiver for RTTY Autostart," *Ham Radio*, December 1972, p. 27. This article describes a fixed frequency receiver for the RTTY aficionado interested in autostart operation. Unattended autostart operation requires more than just a receiver with good sensitivity and selectivity. It requires the receiver to be ultrastable since, as previously stated, the station is unattended. For this reason, the receiver described in this article is crystal controlled.

Lichtenwalner, B.D. "The Computer QSO Machine," *73*, January 1976, p. 80.

This unit is capable of sending the time (hours and minutes), the date (year, month, and day), a preprogrammed message, and a CW ID. This unit is typically used in an answer-back system. When tripped by an access code, the time, date, message, and CW ID are broadcast, indicating the equipment is up and running.

Sanders, L.W. "RTTY Autocall — the Digital Way," *73*, February 1976, p. 76.

This article describes a selective calling unit (Selcal). Of particular note is that the unit uses integrated circuits rather than a mechanical stunt box.

Advanced Projects

Guthrie, R.D. "ASCII/Baudot with a PROM," *73*, June 1976, p. 114.

There are many commercial video display units on the market for those who don't like the clatter of a teleprinter. Unfortunately, these commercial units are geared for the computer hobbyist and, as such, accept only the ASCII code. This article describes a circuit that will convert the Baudot code to ASCII, so an amateur RTTY station can use one of the commercially manufactured video display units.

Hoff, I.M. "The Mainline UT-4," *RTTY Journal*, February, March, April, May 1974.

This series of articles describes the UT-4 which is a UART/FIFO combination capable of regenerating the received signal and electronic speed conversion. It's an advanced project but most worthwhile to the serious RTTY aficionado.

Hutton, L.I. "Build This Exciting New TVT," *73*, March 1976, p. 76.

This article describes two projects. The first is a home brew electronic keyboard that generates the Baudot code. The second portion of the article describes a Baudot to ASCII converter and a TVT character generator.

Levy, S.P. "A Morse to RTTY Converter," *73*, June 1976, p. 106.

If you like sending CW but not receiving, this article is for you. The circuit makes use of a microprocessor to convert CW to ASCII or Baudot. It sure would be nice to have the next time you have to take a code test at the FCC.

Mooring, E.E. "Phase-Shift RTTY Monitor Scope," *Ham Radio*, August 1972, p. 36.

There are many different methods that one can use to tune in a RTTY signal properly. This unit uses the phase shift method and a CRT display. This technique is superior to most other methods, since the CRT display gives a great deal of information. It is possible to tell at a glance if the other station is transmitting wide or narrow shift, if the mark and space signals are reversed, and much, much more. This is a nice amenity to add once you have a station running.

Miscellaneous

Alexander, D. "The First Computer-Controlled Ham Station," *73*, August 1976, p. 82.

This very interesting article describes the amateur RTTY station of the grand prize winner at the 1976 Altair Computer Convention. If you want to get some idea of the flexibility of a computer-controlled amateur RTTY station, this article is for you.

Brehm, R.C. "RTTY Goes Modern," *73*, February 1977, p. 82.

This article is a must for the beginner who wants to know the history of amateur RTTY. The author concludes with a prognosis for RTTY and its ever increasing comradeship with microprocessors.

Green, W. "Thirty Years of Ham RTTY," *73*, November 1976, p. 110.

An interesting article describing the history of amateur RTTY and is by one who was around during its infancy. Also included are pictures of antique RTTY gear.

Design An Active RTTY Filter

-- eliminate CW QRM and noise

This project started several months ago when I became interested in RTTY and bought a copy of the ARRL's *Specialized Communications Techniques* to learn something about RTTY demodulators. But I couldn't quite see why, in this day and age, anyone in his right mind would want to build RTTY equipment with *tubes*. It seemed antediluvian.

The next thought was that perhaps the LC filters used in most current demodulators could be replaced by *active filters*. An active filter is made with an operational amplifier IC such as the popular 741, plus a few resistors and capacitors. Though it has no inductor, it can be tuned just like an LC filter can. It's used in the same way and does the same job. Aside from lacking an inductance, the active filter has one big advantage — its resonant frequency and its Q can easily be adjusted with potentiometers. A conventional LC filter requires removing turns from a toroid and/or hand-picking capacitors to find one with just the right value.

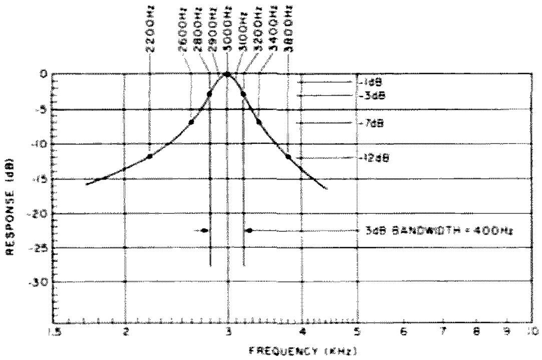

Fig. 1. Simple bandpass filter response curve.

In this article you will find not only several filters useful for RTTY, but also a complete description of how they were designed. Following these simple steps you could design other useful filters as well.

This description will concentrate on bandpass filters. In a good RTTY demodulator, a bandpass filter is used at the input to separate the desired RTTY tones from noise and QRM. This filter has to have fairly constant gain throughout the middle of its passband so that all needed RTTY information can pass through without distortion. But to reject the most QRM its response should drop quite fast to either side of the desired frequency range. This is a fairly tall order for a filter and usually requires the use of three 88 mH toroids and a batch of capacitors which are *very* carefully chosen. With active filters the three toroid filter stages are replaced instead with three op amp filter stages. Separate filters are used for receiving 170 Hz shift and 850 Hz shift RTTY signals.

In case your knowledge of filters needs a little brushing up, the following discussion will help bring you up to date and also explain why three stages of filtering are needed.

Single-Stage Filters

The frequency response of a one stage bandpass filter is shown in Fig. 1. This particular filter is resonant at 3000 Hz and has a bandwidth of 400 Hz. This means that the peak in the response curve is at 3000 Hz. This is the frequency where the filter has a maximum gain.

The bandwidth is measured by noting those frequencies where the gain drops to 70% of its maximum value. In terms of decibels, this is equivalent to a loss of 3 dB gain from its maximum value at the top. For the sake of simplicity, the gain at the top is usually defined as 0 dB, in which case the gain at the 70% points is -3 dB. The two frequencies where this occurs (see the plot) are 2800 and 3200 Hz. Since the difference between them is 400 Hz, we say that the bandwidth is 400 Hz. Sometimes, just to be precise, we say that "the 3 dB bandwidth is 400 Hz."

The "quality" of a bandpass filter is judged by how narrow the bandpass is in relation to the center frequency. This "quality factor" is called Q, and is defined as Q = resonant frequency/ bandwidth. In this case, the Q is 3000/400 or 7.5, while typical Qs range from 2 or 3 up into the hundreds in some cases.

If you know the resonant frequency and the Q of a filter circuit, it is easy to draw an approximate

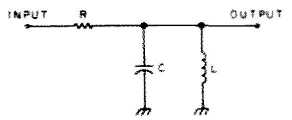

Fig. 2. Simple LC bandpass filter.

100 Hz away	(2900 and 3100)	the response is	-1 dB
200 Hz away	(2800 and 3200)	the response is	-3 dB
400 Hz away	(2600 and 3400)	the response is	-7 dB
800 Hz away	(2200 and 3800)	the response is	-12 dB

Table 1.

response curve. First, you use: bandwidth = resonant frequency/Q to solve for the bandwidth. Then you assume that the bandwidth of the filter is centered evenly around the resonant frequency. (This is usually not true, so you get a slight error when you do it.) If you divide the bandwidth by two, this tells you how far to go each side of the center frequency to find the -3 dB points. In this case the bandwidth is 400 Hz, so you go 200 Hz each side of 3000 to find the -3 dB points.

Other points on the curve can be gotten if you remember that halfway to the -3 dB point the response is at -1 dB, while twice as far away the response is at -7 dB, and four times as far as the -3 dB point the curve is at -12 dB.

In the example of Fig. 1, this works as shown in Table 1, using the center frequency of 3000 Hz as the reference.

Simple filters of this type have a curve which falls off 6 dB for every octave. What that means in this case is that each time you double the distance from the peak the response would drop by another 6 dB. Hence 1600 Hz away the response would be at -18 dB, 3200 Hz away it would be at -24 dB and so on. Most practical filters, however, completely stop dc and very low frequencies. As a result their response curve drops much faster for the low frequencies, and much slower for high frequencies than the above would make you think. Nevertheless, the above calculations are useful for high Q filters as long as we do not get too far away from the center frequency.

Bandpass responses such as Fig. 1 can be approximated by simple LC filters such as the one in Fig. 2. Because this filter has two reactive elements — one inductor and one capacitor — it is called a *two-pole* filter.

Two-pole filters can also be built with op amps as shown in Fig. 3. Many different kinds of op amps can be used with just minor changes in biasing. My favorite happens to be the 741, so that is what is shown here. Because it has two reactive elements — both capacitors — such a filter is also called a two-pole filter. (In many cases there may be more capacitors used for bypassing or coupling. These are not part of the filtering action and don't count toward the number of poles. If in doubt, check whether changing a capacitor's value changes the resonant frequency or the Q. If it does, then the capacitor counts as a pole.)

The circuit of Fig. 3(a) uses only one op amp, and is usable only for Qs less than 10. The component values are easy to find from the following equations. Given the resonant frequency f, the Q, and the desired gain G, choose a convenient value of capacitance C. For typical audio filters C is often 0.01 or 0.1 uF. Then,

$$R1 = \frac{Q}{2\pi fGC}$$

$$R2 = \frac{Q}{(2Q^2 - G)\, 2\pi fC}$$

$$R3 = \frac{2Q}{2\pi fC}$$

$$R4 = R3$$

where π = 3.14. The value for R2 is the exact value assuming all the other components have the exact values calculated. Usually R2 is a pot about twice the calculated value, which is then used to precisely set the resonant frequency. Making R2 twice the calculated size makes the final setting come out about midway in the pot rotation.

To get higher Qs requires two op amps as shown in Fig. 3(b). This circuit works for Qs in the range from 10 up to about 50. Component values for this circuit require a little more work to calculate.

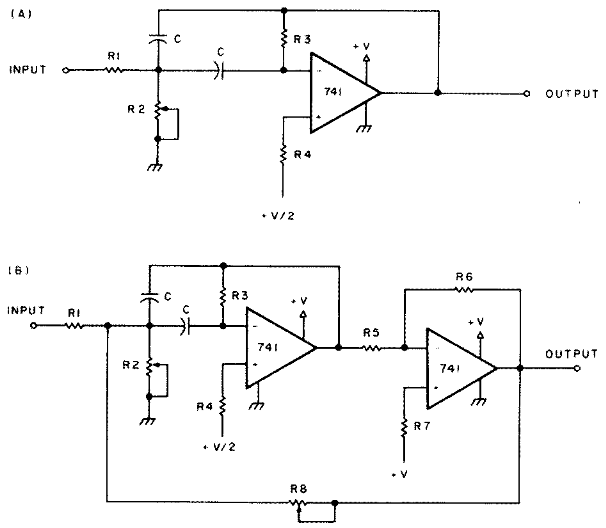

Fig. 3. Two-pole active bandpass filters. (a) Single op amp for Q less than 10. (b) Two op amps for Q between 10 and 50.

This circuit does not work well for low gains. It is at its best when the gain is somewhat greater than the square root of Q. For instance, if the filter is designed for a Q of 16, then the gain should be greater than 4. Usually we design for a gain several times greater than that, perhaps in the range from 8 to 20.

Once you have decided on the values for the resonant frequency f, the Q, the gain G, and the capacitors C, the following equations are used to find the resistor values:

$$R1 = R3 = R4 = R5 = \frac{Q}{2\pi f C}$$

$$R2 = \frac{R1}{Q^2 - 1 - \frac{2\sqrt{Q}}{G} + \frac{1}{G\sqrt{Q}}}$$

$$R6 = \frac{G\,R1}{\sqrt{Q}}$$

$$R7 = \frac{R5\,R6}{R5 + R6}$$

$$R8 = \frac{R1\,G\sqrt{Q}}{(2Q-1)}$$

While these equations look quite complex, any calculator will have them solved in a very short time.

Assuming that the values of the capacitors are exact (which is unlikely), these equations would give exact values for all the resistors. Usually, though, the capacitors will not be exactly the values used in the calculations, and the resistors will probably be the nearest standard values rather than the exact values found from the equations. In this case the circuit has to be adjusted to give just the right center frequency and the right Q. The normal approach is to make R2 and R8 pots of about twice the calculated value. R2 is then used to adjust the center frequency while R8 is used to adjust the Q. There is a slight interaction between the two pots, so you must repeat the adjustment two or three times.

When building active filters you must use good components. Do not use disk capacitors, even for testing! Every time you breathe on them they change value with the change in temperature. Polystyrene or polycarbonate capacitors are best, followed by mylar or mica capacitors. Also use good op amps. 741-type amps (which include the 1458, 5558 and 747) provide good performance up to several kHz. High frequency op amps may be needed for higher frequencies. I have had bad luck using the LM3900. Its gain is too low for reliable operation

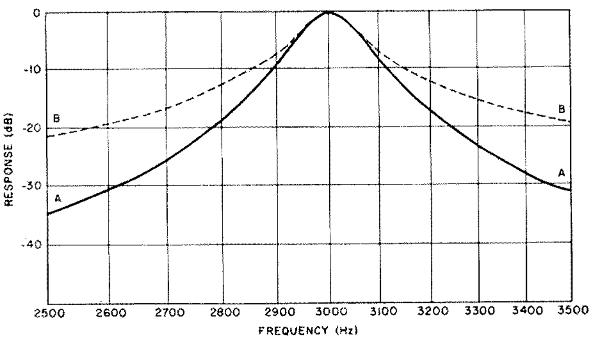

Fig. 4. Comparison of two-pole and four-pole filters.

in these circuits at the frequencies used for RTTY. Moreover, do not use dual or quad op amps such as the 1458 or 5558 in the same filter. Under some conditions the internal coupling between two amps in the same IC will produce strange results. It is best to use single 741 amplifiers.

Filters with Very Narrow Bandpass

There are different ways of building a narrow bandpass filter. You can use one stage of filtering with a high Q or use several stages cascaded (connected one after the other) with lower Q. Both approaches are often used. Cascading LC filters require

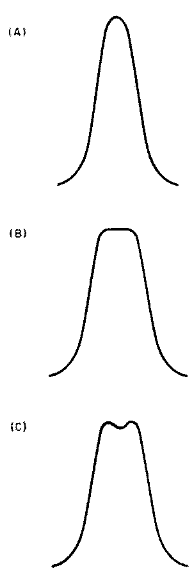

Fig. 5. Effects of coupling (or stagger tuning) on response of bandpass filter. (a) Under coupling. (b) Critical coupling (Butterworth). (c) Over coupling (Chebyshev).

careful mathematical analysis, since connecting LC filters together causes them to load each other down. As a result often the bandwidth gets bigger rather than smaller. Active filters, on the other hand, can be connected together without loading each other because they generally have a high input impedance and a low output impedance. Connecting several low Q stages (wide bandwidth) together really does narrow down the bandwidth.

Although filters with a very narrow bandpass are not generally needed for RTTY, it's useful to examine what happens anyway. Fig. 4 shows the difference between one high Q filter and two low Q filters in cascade. Curve A is for two cascaded filters, both tuned to 3000 Hz and a bandwidth of 150 Hz, while the two together have a bandwidth of only 96 Hz. Curve B is a single filter with a Q of 31.2, which also has a 3 dB bandwidth of 96 Hz.

Although the two sets of filters have almost the same response very close to 3000 Hz, they are very different far away from 3000 Hz. The single filter (Q = 31.2) is a two-pole filter which, as we mentioned earlier, results in the response dropping 6 dB each time we double the distance away from the center frequency. For example, at 3200 Hz the response is about -12 dB, while at 3400 Hz it is about -18 dB.

Combining two filters as in curve A makes this a four-pole filter whose response falls off twice as fast, in this case at 12 dB per octave. For example, at 3200 Hz curve A is at about -17 dB, while at 3400 Hz it is at about -29 dB. We note that 3400 Hz is twice as far from 3000 as 3200 is, and the gain is about 12 dB lower. From this example we see that a four-pole filter can be designed to have the same bandwidth as the two-pole filter, but its response falls off much more quickly to each side of the center frequency. In the same way, a six-pole or eight-pole filter would have even steeper sides to its response curve, decreasing at 18 dB per octave and 24 dB per octave, respectively. When talking about i-f amplifiers, we would say that an eight-pole filter has a better shape factor than a two-pole, meaning that it drops off faster. (You may have noticed eight-pole or ten-pole filters mentioned in ads for 2 meter FM transceivers.)

Wide Bandpass RTTY Filters

A typical RTTY demodulator – or TU for Terminal Unit – needs several filters for separating the RTTY tones from noise and also from each other. Two common sets of frequencies are used. The pair of 2125 and 2295 Hz is separated by 170 Hz and is used with 170 Hz shift, while the pair of 2125 and 2975 Hz is separated by 850 Hz and is used for 850 Hz shift. The first filter in a good TU is used to separate these tones from the rest of the audio coming from the receiver.

For use with 170 Hz shift, the filter used is centered about 2200 Hz, and usually has a bandpass of about 260 Hz, which then extends from about 2070 Hz to about 2330 Hz. This covers more than the 170 Hz difference between the tones, and is necessary to allow reception of some of the audio sidebands produced by keying as well as to allow a small amount of drift.

For use with 850 Hz shift, the filter used is centered around 2550 Hz and usually has a bandpass of about 1100 Hz, which then extends from roughly 2000 Hz to about 3100 Hz.

In either case, we need a filter which will give fairly constant amplification over the bandpass of 260 or 1100 Hz, while at the same time providing a steep rolloff for frequencies outside that range. We find that a two-pole filter could give the wide bandpass, but that its response would not fall steeply enough outside the range to reduce QRM to an acceptable level. What we need is a multiple pole filter which will have steep skirts – response whose sides fall off very fast. Most of the filters used for this purpose are six-pole designs dating back to a series of articles in *QST* and in the *RTTY Journal*, written by Irvin Hoff K8DKC/W6FFC. Each of these filters uses three parallel-tuned LC circuits which are critically coupled to each other. Each of the LC circuits provides two poles, for a total of six.

As shown in Fig. 4, cascading several bandpass filter stages gives steeper response skirts but still results in a rounded top. As it turns out, if a six-pole filter were built out of three two-pole stages all tuned to the same frequency, it would be impossible to get both steep skirts and a wide enough top to pass the entire bandpass without seriously dropping off at the edges. In order to get a good enough response curve, it is necessary to stagger-tune the three filters so that each stage emphasizes a different part of the bandpass. In this way the top of the bandpass curve is spread out and flattened, while the steep skirts are retained.

The original Irv Hoff filters all did this by properly coupling the three LC resonant circuits. As the oldtimers will remember, all the old electronics books discussed what happens when

the tuned primary of an i-f transformer is overcoupled to the tuned secondary. The top of the i-f response curve flattens out and in extreme cases develops a dip in the middle. (You don't read about this much in modern books because modern i-f transformers tend to have only one tuned winding.) Anyway, Irv Hoff's designs did just that – by coupling the three LC circuits he was able to broaden out the response curve so that it had a fairly flat top with steep sides. Fig. 5 shows the effect of coupling on two LC circuits. When they are undercoupled, as at (a), the response is sharp and thin with a smoothly rounded top. With critical coupling (b) the top flattens out, while with overcoupling (c) the top acquires a dip. Many old electronics textbooks had curves just like these.

With active filters, the separate filter stages in cascade are completely independent of each other so there is no such thing as overcoupling. Instead, the same effect can be achieved by stagger-tuning the stages and by carefully adjusting their Qs. When the overall filter is adjusted so that the top is as flat as possible, as in Fig. 5(b), the filter is then called a Butterworth filter. If it has one or more dips in it, as in Fig. 5(c), it is called a Chebyshev filter. While the Chebyshev generally has steeper skirts than the Butterworth, it tends to distort pulses like those of RTTY, and so Butterworth filters are used more commonly. Hoff's filters, as well as those in the popular ST-6 demodulator, are six-pole Butterworth filters.

The correct design of a Butterworth or Chebyshev filter is very hard to do with LC filters, but amazingly easy to do with active filters – once you know how. It's just a matter of knowing how to choose the center frequency and Q of each filter stage. The whole process can be done with graph paper, a compass, and a protractor in a few minutes.

In the following example we will design an input filter for a 170 Hz shift RTTY demodulator. As mentioned earlier, we want a Butterworth filter with a center frequency of 2200 Hz and a bandwidth of 260 Hz.

Start by getting some graph paper with small squares, a compass, and a protractor. Along the bottom of the graph paper, draw a long horizontal line and label it with frequencies so that the center frequency of the filter is somewhere near the center, and the 3 dB bandwidth of the filter is centered around it. Make use of the graph paper's lines to evenly space out the frequency steps, and use graph paper with equal size squares throughout. (Don't use the log graph paper normally used for frequency response diagrams.) See Fig. 6 for an example of how to label the line.

FF	Correction Factor (Degrees)
0 to 0.01	0
0.01 to 0.025	1
0.025 to 0.04	2
0.04 to 0.06	3
0.06 to 0.08	4
0.08 to 0.1	5
0.1 to 0.11	6
0.11 to 0.13	7
0.13 to 0.15	8
0.15 to 0.17	9
0.17 to 0.19	10

Table 2.

Now take your compass and draw half a circle centered on the center frequency of the filter, with a diameter exactly equal to the desired bandwidth. This circle should then touch the line exactly at the lower 3 dB frequency (2070 Hz in our example) and also at the upper 3 dB frequency (2330 Hz in our example). If you were designing a Chebyshev filter, then instead of a circle you would use an ellipse whose height would depend on how large the dips in the response should be.

Now see Fig. 7. Depending on the number of poles needed, look at the appropriate drawing in Fig. 7 to see the location of the dots. In this case we want to duplicate the performance of the Hoff filter in the ST-6 demodulator, so we will use a six-pole filter. (Usually, you would have to decide how many poles to use based on the desired steepness of the bandwidth curve skirts.) As shown in Fig. 7, we want one dot up at the very top of the circle, with two more exactly 30 degrees up from the line. Now go back to your drawing and use the protractor to draw in the dots. For our filter we get the dots shown in Fig. 6, and labeled A, B, and C. (In electrical engineering language, this drawing would be called the s-plane and the dots are the *poles*. A six-pole filter has six poles, of which only three are shown in this drawing. The other three are not used.)

If we were using an ideal filter having only the poles shown, we would use the points A, B, and C which we have drawn. There are, however, those other three poles not shown in the drawing as well as the fact that the filter

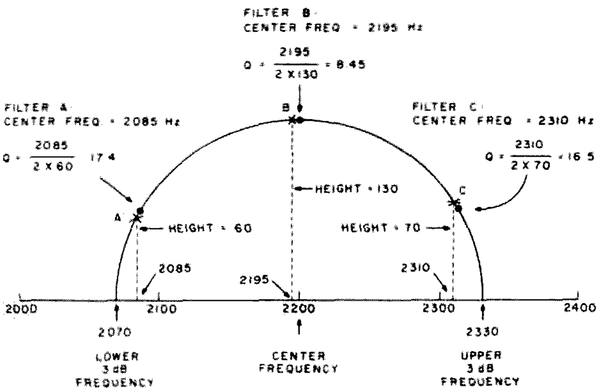

Fig. 6. Designing a Butterworth RTTY input filter for 170 Hz.

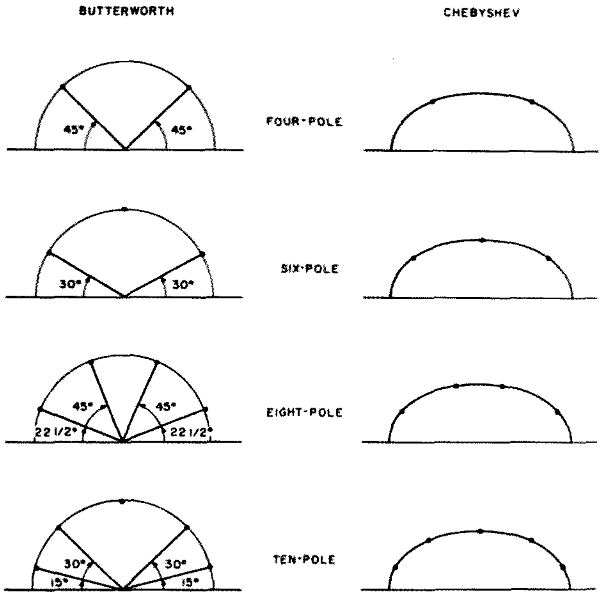

Fig. 7. Pole locations for Butterworth and Chebyshev filters.

Stage	Center Freq.	Q
A	2085 Hz	17.4
B	2195 Hz	8.45
C	2310 Hz	16.5

Table 3.

stages do not pass dc. Although their effect is not very obvious, they do cause a slight error in the final filter which we have to try to remove. And so here we apply a small "Finagle Factor."

Compute the quantity, FF = Desired filter bandwidth/(3 x Center Frequency).

In our sample filter this comes out to (260)/(3 x 2200), which is equal to 0.04. Now look up this FF (Finagle Factor) in Table 2.

Now return to Fig. 6, and move all the poles *left* by a small angle as shown by the above table. In our example the finagle factor is .04, so we move all the poles left about 3 degrees. This puts them at the locations labeled with an X. These three poles determine the actual performance of the whole filter. (Remember, there are three more poles not shown, for a total of six.)

Each of these poles will be produced by one of the three stages of the filter, and each pole determines the center frequency and the Q of that stage. The center frequency is easily read off the graph by drawing a line from the X straight down the horizontal line and reading the frequency off the scale.

To find the Q, carefully measure the height of the X above the horizontal line. Use the frequency scale to judge the height. In the case of the pole labeled A, its height is about 60 cycles (or is it 60 Hertz?). Calculate the Q of each stage from Q = Center frequency of filter/2 x Height above line. For pole A this works out as a center frequency of 2085 Hz and a height of 60, so the Q is 2085/120 = 17.4.

To build the overall bandpass filter with a bandwidth of 260 Hz we need three staggered filter stages with the center frequencies and Qs as shown in Table 3.

Fig. 8 shows the overall circuit for the entire filter. Since filter stages A and C have Qs above 10 we use the double op amp circuit shown in Fig. 3(b). The Q of stage B is below 10 so the circuit of Fig. 3(a) is good enough. As mentioned earlier, the double amplifier circuit works best when the design gain is several times the square root of Q. For Qs around 17, the square root is slightly above 4, so I designed these circuits for a gain about three times higher, or about 13. Stage B was arbitrarily designed for a gain of 2. There is nothing magic about these gains, and the final circuit will have different gains anyway, so there is little you can do here to obtain precise gains. The problem is that the gains would be exactly as specified if all of the components we used were exactly equal to the values calculated from the equations. But, since we have to rely on standard value resistors as well as possibly large tolerance errors, by the time we finish trimming the resonant frequency and the Q with the potentiometers, the gain will wind up considerably different from the assumed values. So the trick is to design for considerably more gain than you really need and use an external potentiometer as a level control to cut it back to the desired value.

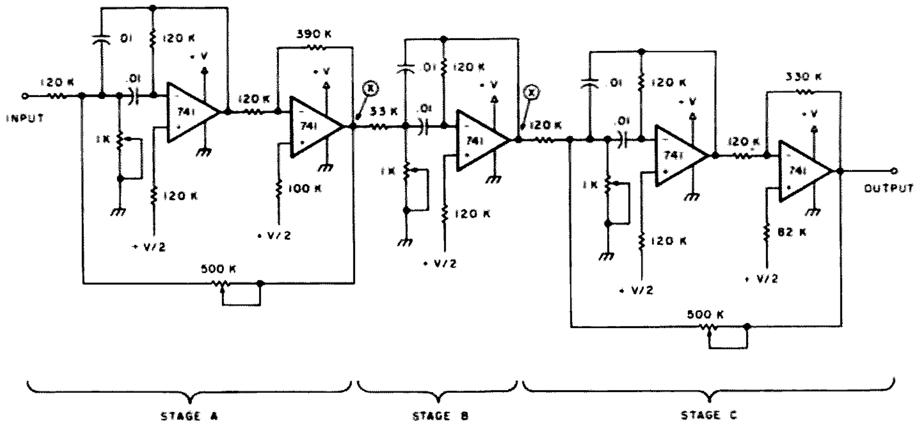

Fig. 8. 170 Hz shift bandpass input filter.

To permit trimming the center frequency of each stage and the Q of the two end stages, five of the resistances calculated are replaced by potentiometers as shown in Fig. 8. (By the way, the three stages could have been connected together in any order.)

Alignment of the filter is easy. The three stages are disconnected from each other at the points marked X, and each stage is aligned separately. First, the 1k pot is adjusted to peak the gain at the center frequency. Then the 500k pot (for the two amplifier circuits) is adjusted to make the bandwidth correct. There is a slight interaction between the two adjustments, so the process is repeated two or three times. Once the three stages are adjusted separately, they are connected together.

Fig. 9 compares the response of this active filter

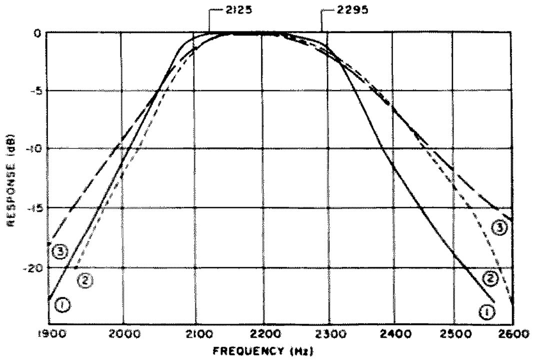

Fig. 9. Response of two LC filters and one active filter.

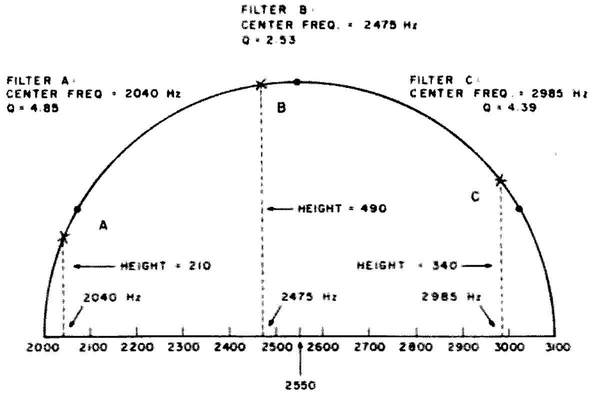

Fig. 10. Designing a Butterworth RTTY input filter for 850 Hz shift.

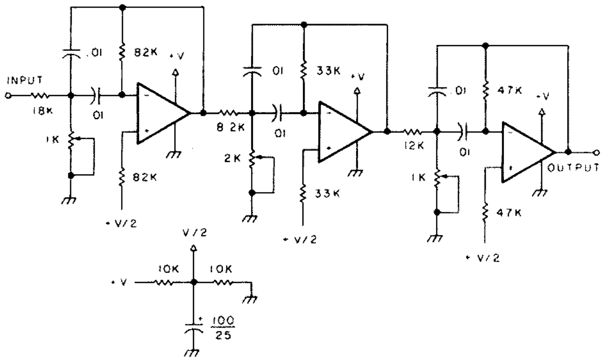

Fig. 11. 850 Hz shift bandpass input filter.

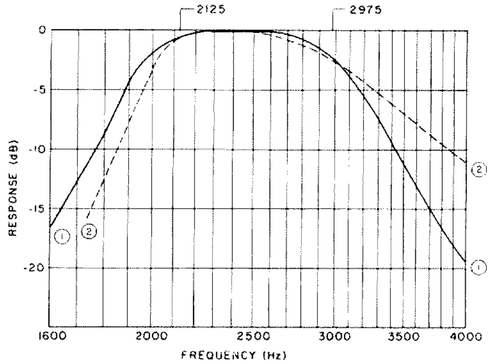

Fig. 12. Frequency response of 850 Hz input bandpass filter.

with two other filters. Curve 1 is the active filter we have just designed. Curve 2 is the curve published by Irv Hoff for his LC filter in *QST* more than ten years ago. Curve 3 is the 170 Hz shift filter in my ST-6 demodulator (built from a HAL kit). As you can see, there is remarkable similarity between the original Hoff design and the active filter we have designed. Both are Butterworth filters with 260 Hz bandwidth, so both should be very similar.

Another filter needed in a RTTY demodulator for 850 Hz shift is a bandpass filter with approximately 1000 or 1100 Hz bandwidth, which will pass the 2125 and 2975 Hz tones plus a little more to allow for modulation sidebands and drift. Though I won't go through the details of this design, it is shown in Figs. 10 and 11. Fig. 11 also shows how the 741 op amp is biased when used with a single power supply. The positive voltage, called +V, is divided with two 10k resistors to give a bias voltage called +V/2, which is then connected to the + inputs on the op amps to provide bias. In this way the inputs and outputs of the op amps are biased to run at half of the supply voltage. For instance, if a 12 volt supply is used, this voltage divider provides +6 volts, so the inputs and outputs of the op amps run at +6 volts. Though not shown in Fig. 8, this voltage divider is needed there also.

Fig. 12 compares the response of this active filter (curve 1) with the similar 1100 Hz filter in my ST-6 (curve 2). (I will have to look at that ST-6 filter to see whether it is properly aligned!)

In conclusion, let me encourage you to design and build your own filters, whether it is for RTTY or other uses. It is fun and, with this graphical approach and the equations presented earlier, even relatively easy. ■

Moving Display RTTY Readout

-- just like Times Square

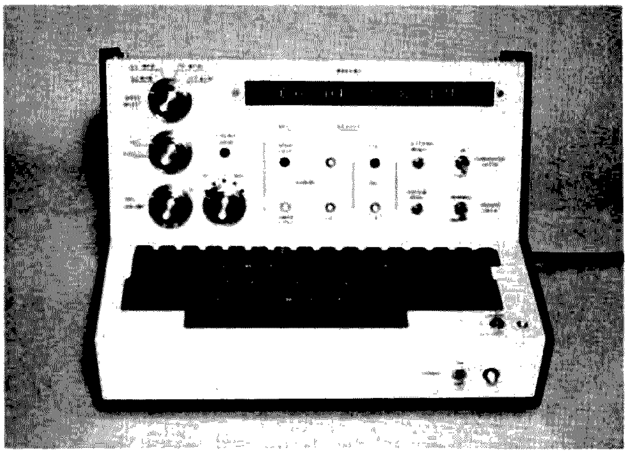
Francis J. Ferrara WB8SWH
PO Box 56
Enon OH 45323

The desire to build an all-electronic RTTY system without incurring the high price tag that usually accompanies video display units in this class is what prompted the construction of this terminal. The unit uses, instead of the CRT normally associated with video systems, a series of 16 alphanumeric type displays, each with the capability of reading out any one of the 64 standard ASCII characters. The readouts are clocked in such a manner that the generated words appear to "walk across" the display screen from right to left. Provision is made for tape recording the incoming signal for playback at a later time. This provision helps offset the potential problem of there being no hard copy available. Also included is a keyboard monitor feature, which allows the operator to see his transmitted copy as it is sent out over the air. The circuit, which uses 6 level ASCII code for internal signal processing, utilizes a series of 3 read only memories (ROMs) to permit compatible operation with the 5 level Baudot code. The system has been designed so that it is only a matter of throwing one switch to realize straight ASCII operation.

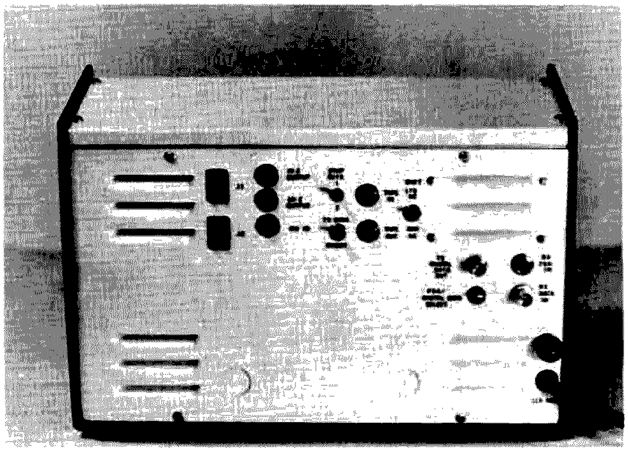
Receive Circuit Description

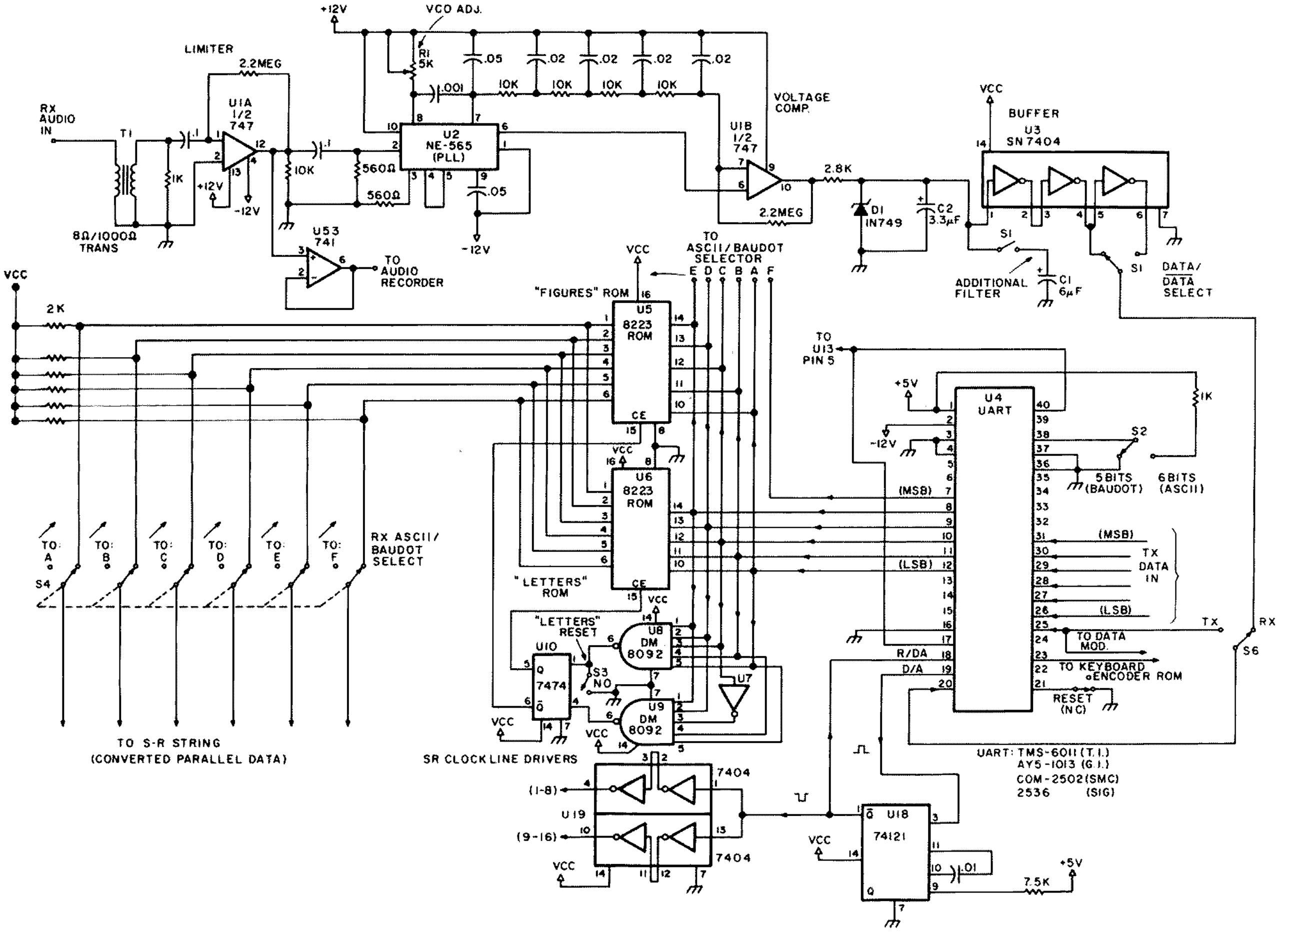
The system starts from scratch, due to there being no RTTY equipment on hand at the onset of the project. Signal demodulation is accomplished by a phase locked loop, U2, with the receive signal first passing through limiter amp U1a. The limiter amp also drives a unity gain isolation amp, U53, and signals for a tape recorder may be taken at its output. The VCO in the NE565 PLL tracks the mark and space tones, and the VCO control voltage drives voltage comparator U1b, causing positive and negative voltages in direct proportion to the transmitted marks and spaces.[1] Zener diode D1 makes the output TTL compatible by cutting off the negative-going portion of the signal and limiting the positive peak to 5 volts. Buffer U3 aids as a signal conditioner by shaping the rising and falling edges. The 6 uF capacitor, C1, serves as additional filtering by slowing the frequency response of the comparator amp, and is very effective in reducing short duration noise. If a suitable terminal unit with a TTL output is available, then the PLL converter can be left out. The converted output is then fed into the serial input of the UART chip, U4. The UART strips off the start and stop bits and outputs the corresponding parallel code, 5 bits for Baudot and 6 bits for ASCII. This word then addresses the two 8223 ROMs (U5 and U6) which convert the Baudot code into ASCII. Should the ASCII mode be selected, then no conversion takes place and the data is switched directly to the display section. Inverter U7 and AND gates U8 and U9 form a character recognition circuit which detects "letters" (lower case) and "figures" (upper case) commands. The output of this circuit sets flip-flop U10, which enables the appropriate ROM and disables the other. ROM outputs are "open collector" and may be tied directly in parallel. They need not be gated. Push-button switch S3 is pro-

Front view of RTTY unit.



View of rear panel.

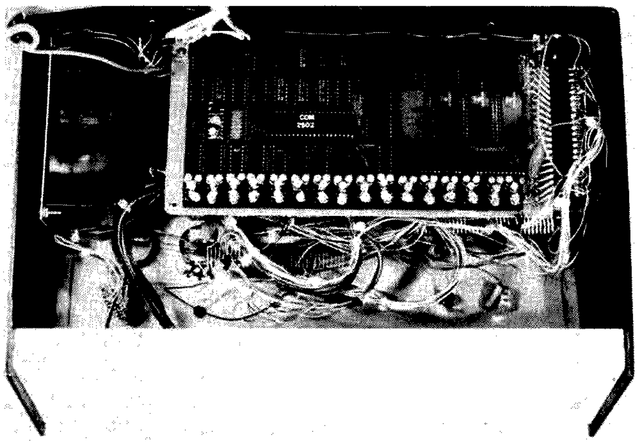




vided to manually reset the "letters" ROM should it miss the automatic command due to noise, QRM, fades, etc.

Display Section

The parallel data is then applied to the input of the shift register chain. Each shift register directly corresponds to a display, and all are clocked simultaneously from the Data Available flag on the UART, through driver U19, to cause the characters to move along from display to display. The output of each shift register is sampled by multiplexers U37-U42, which are all clocked in parallel and, together with U11, form the horizontal scan generator circuit. A multiplex frequency of approximately 4.8 kHz was selected to provide flicker-free operation of the displays. The outputs of the multiplexers are then inverted and fed into the 2513 character generator, U43. The six inputs from the multiplexers constitute an address and a five line dynamic parallel signal is produced at the 2513 output. The signal is again inverted and drives de-multiplexers U45-U49, which are all parallel clocked with the multiplexers. The de-multiplexers distribute the



The RX/driver circuit board. Driver transistor modules are on the top, with the character generator, multiplexers, and de-multiplexers on the left side. The UART is in the center with the character recognition circuit above it; the two RX code converter ROMs are to the right. The shift register string occupies the bottom two rows on the right. The +5 volt power supply is mounted on the right wall.

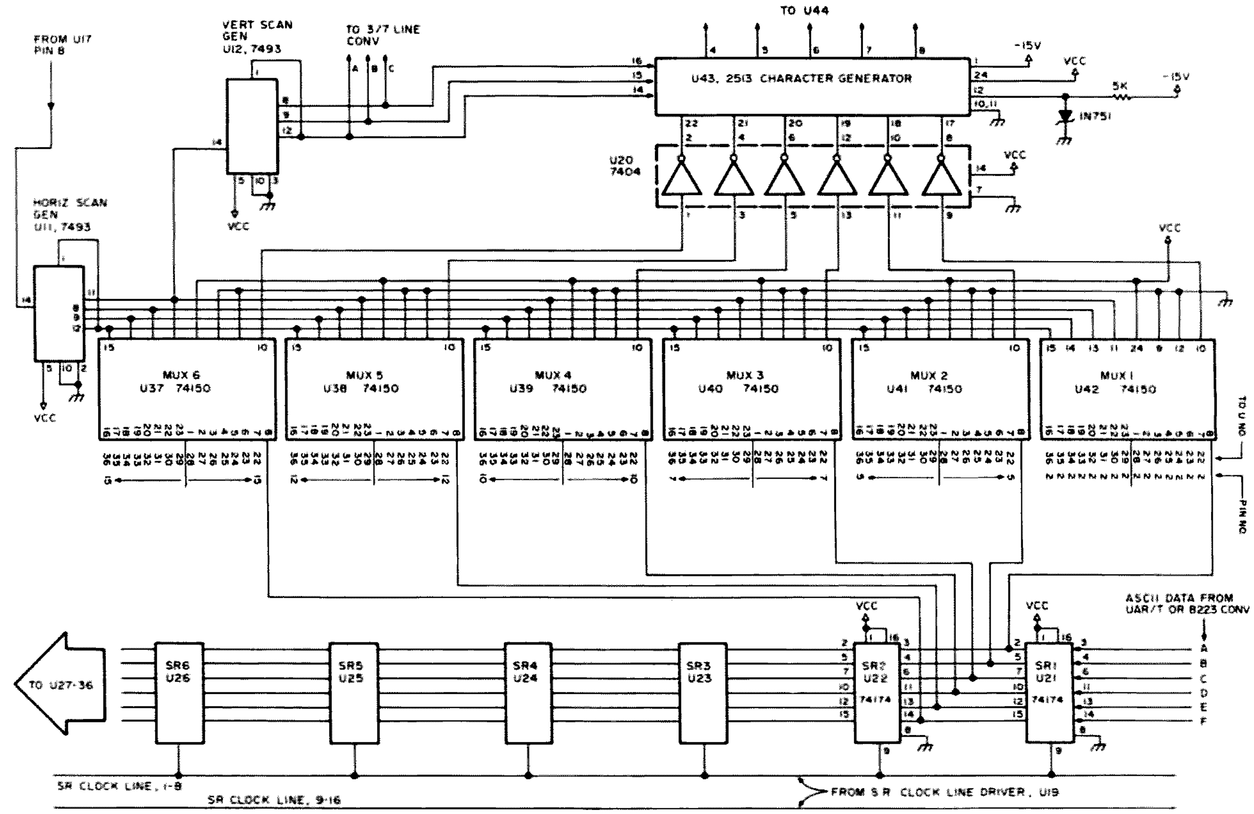

Fig. 2.

signals to their respective displays through driver transistors Q8-Q87. Multiplex clock U11 drives a second binary counter, U12, which is used to clock both the character generator and the 3-line to 7-line converter. The resulting scan is from right to left and from top to bottom, with the vertical row advancing 1 count downward for every 16 horizontal sweeps.

Baud rate selection and the multiplexer clocks are derived from a master oscillator. 38.4 kHz was used in this model because of the availability of a stable module, but an NE555 oscillator circuit may be used in its place. The UART chip is designed to be clocked at 16 times the desired baud rate for both the transmit and receive functions. One design goal was to make the system operable on the four commonly used speeds of 60, 66, 75, and 100 wpm (45, 50, 57 and 75 baud respectively). The four clocks are generated from the master oscillator using a divide by "N" counter chain (U14 and U15), with "N" being derived by programming a multi-deck wafer switch to produce the binary divisors required. The output of the counter chain is a very narrow pulse at twice the desired frequency. This pulse is applied to flip-flop U13, which halves the frequency and produces a symmetrical waveform. The clock frequency does not have to be exactly 16 times the data rate, incidentally, as the UART is capable of tracking receive signals over a small range (approximately ± 5%), and in most cases this is sufficient to make up for any differences between the transmit and receive clocks. However, the correct speed range

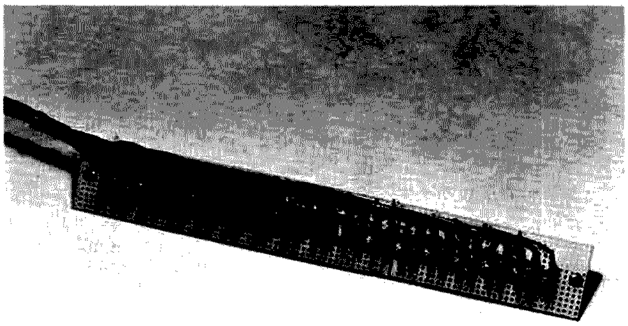

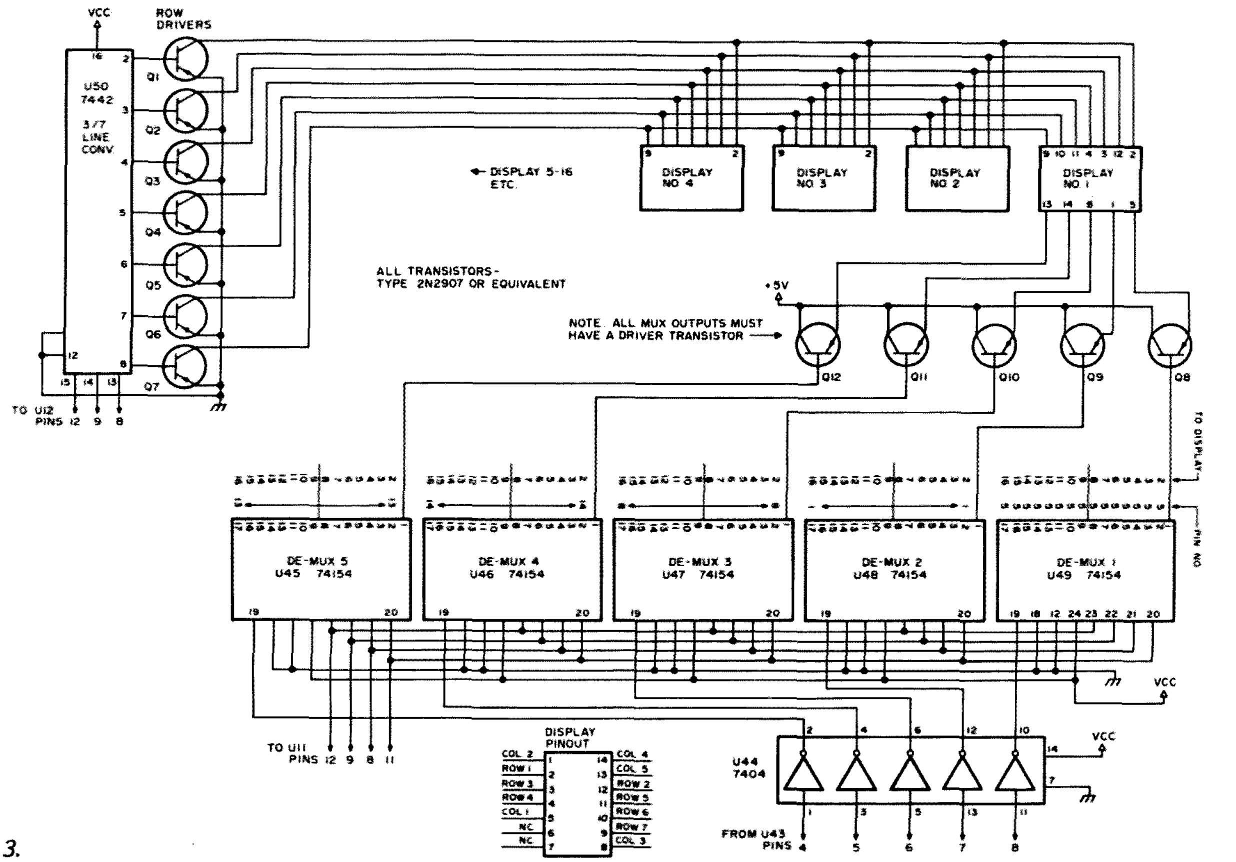

Fig. 3.

must be manually selected.

Transmit System

The transmit system is relatively straighforward. The keyboard addresses an encoder ROM which directly outputs an ASCII word and produces a transmit strobe pulse.[2] The output of the encoder ROM is fed into the code converter ROM which turns the ASCII data into Baudot, or passes it directly through, depending on the mode. Then the output of the converter ROM addresses the data inputs on the transmit side of the UART. The transmit strobe pulse from the encoder ROM is used to "key out" each character, and occurs whenever a key on the board is depressed. The serial digital output from the UART then branches out, with one line going back into the receive side for transmit monitoring, and the other line driving the AFSK modulator. The modulator is then outputted to the audio section of an SSB transmitter.

To facilitate construction, a commercially manufactured unit (HAL AK-1) was used as the AFSK section.

Construction

The two main circuit boards, which contain the digital electronics and the PLL converter, were fabricated using the wire-wrap technique. Utilization of

other construction techniques is possible, but will most likely result in the finished unit taking up considerably more space than the prototype. The MAN-2 displays were mounted in wire-wrap sockets (which were used extensively throughout the unit) and attached to a section of vectorboard. The wiring harness between the digital and display boards was formed and carefully labeled on the digital board, bundled together, and run out to the displays. There, the wiring was custom fitted to each display. This results in a much neater package than if the lines were run out individually.

Power supply current is on the order of 1.2 Amps from the 5 volt source and 150 mA and 50 mA from the respective -15 volt and +15 volt supplies, using the type chips specified. If a larger 5 volt supply is available, then the more expensive 74LSXX series chips, which were used

only to save power, need not be used. Indeed, excellent results were achieved using the standard 74XX series chips. Power supplies are of the modular type, available at reasonable cost from many discount or surplus houses. Again, for the sake of economy, units could be constructed with discrete components.

The use of a metal cabinet for housing the unit is highly recommended, as the digital circuitry (particularly the clocks and multiplexers) tends to produce a good deal of noise (which will be evidenced in your receiver if steps aren't taken to guard against it). The metal cabinet serves well in keeping this noise inside the unit and out of your speaker.

The output transistors were all mounted on 14 pin component holders for ease of installation, and for possible repairs. Should suitable integrated PNP arrays be available, they could be substituted for the 80 column and 7 row drivers.

Conclusions

At first, it was thought that the displayed words would move across the screen too fast to read, but fortunately this was not the case. Even at 100 wpm, text sent out on reperf tape can easily be read. The fact that most RTTYers don't type more than 20 or 30 wpm makes keeping up with the display that much easier.

The keyboard takes a little bit of extra thought to operate. Due to the coding of the transmit converter ROM, it is necessary in the Baudot mode to hit both the upper case and shift keys to produce the symbols for quotation marks, exclamation point, etc. However, only the upper case key need be struck to produce figures Ø through 9 and the question mark.

The ASCII/Baudot selector switch is located on the front panel, as is the adjustment for centering the VFO on the PLL. This allows for easy tuning of both 170 Hz and 850 Hz shift signals.

The only real drawback of the unit at this time is in the phase locked loop converter, which has a tendency to track and lock onto noise. However, a standard type converter of the ST-5 variety with a TTL configured output would most likely improve performance in this area.

The unit is very compact and portable. Total weight is approximately 12 pounds (substantially lighter than mechanical or even CRT type

systems), and it may be considered for emergency or field day use. Total cost is on the order of $250-$300, which is quite a bit less than most all-electronic systems.

Since the unit has direct ASCII transmit and asynchronous TTY receive capabilities, its use as a computer terminal should not be overlooked. Indeed, if it were designed specifically for this purpose, all of the Baudot conversion circuitry and AFSK devices could be left out, further reducing costs. ■

RTTY SWLing

-- new horizons!

I have been an enthusiastic shortwave listener for years, with a desire to receive everything in the VLF-HF spectrum (10 kHz to 30 MHz). Recently I programmed a Data General Nova mini to give myself a glimpse into an area of SWLing that I had previously left unexplored — radioteletype, or RTTY, for short.

This article will give you a brief introduction to the technical aspects of RTTY, a survey of many types of signals heard, and not heard, and two lists of actual off-the-air RTTY frequencies.

I first learned about the existence of RTTY years ago as a high school student attending an Armed Forces Day open house. While I was tuning around with a system on display there, I came upon a Spanish language RTTY transmission, and I was hooked. Imagine a radio typing at 60 wpm and in a foreign language to boot!

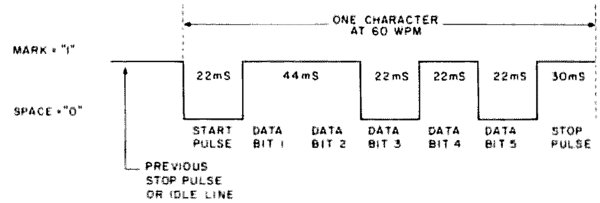

Fig. 1. Typical Baudot 60 wpm RTTY character.

Somewhere along the way I heard that radioteletype was sent at several different "standard" speeds and codes. Not knowing what speeds or codes were in common use was enough to delay my attacking the problem until recently, when I realized what a natural application RTTY SWLing is for a home computer.

RTTY characters are sent as binary data with a series of pulses representing each character. The classical code used for RTTY is commonly called Baudot code. A good deal of what is heard on the air today, including all present US amateur transmissions, is sent in Baudot code.

What the computer hobbyist calls "1" and "0" are called "mark" and "space," respectively, in RTTYese. Mark and space are transmitted by shifting the carrier a small amount to either side of an imaginary center frequency. This is called frequency shift keying, or FSK, for short.

To receive RTTY we need a way to distinguish between mark and space. The most common way is to use the receiver in either CW or SSB mode, with the bfo set above the FSK signal, to produce an audio tone of 2125 Hz for mark and a higher frequency tone for space.

What the computer hobbyist calls a demodulator, the RTTY devotee calls a TU (terminal unit), and it's into this device that the audio tones are sent. The demodulator changes the tones into what the old time RTTY man views as an on/off 60 mA loop current, to drive the selector magnets of his Model 19 machine. Modern demodulators, such as the Dovetron used in my system, provide an additional logic output which is a more welcome input to a computer.

Each character sent in Baudot code is composed of a start pulse, five data bits, and a stop pulse. See Fig. 1. The start and stop pulses are used for synchronization; the data bits define the character. A standard Baudot teleprinter has a set of 52 characters and 5 functions. This is accomplished with only 5 data bits by defining one combination of bits as a "figures shift" function and a second as "letters shift." The Baudot character set is shown in Table 1.

What Frequency Is That RTTY Signal On?

If you are interested in RTTY SWLing, you'll more than likely want to start keeping a log of stations heard. Your log would probably include frequency, shift, speed, sense (upright or inverted), times heard, and maybe a hard copy sample of

some received text. You could exchange this information with other RTTY freaks, go back and listen to favorite stations with a minimum of fuss, etc. Incidentally, one thing you probably shouldn't do is ever let anyone see any of the hard copy text. Unless it's an amateur transmission or clearly of broadcast character (RTTY weather?), it would seem that its disclosure is prohibited by the Communications Act of 1934.

Having decided to start a log, your first problem is what to write down for frequency. What's the standard way of documenting the frequency of a RTTY transmission? The answer, unfortunately, is that there are several "standards" encompassing almost any reasonable method you might devise.

Dyed in the Wool RTTY Ham Method

This method, used by a number of amateurs, is to simply log the frequency of the mark signal. After all, mark is the frequency you're on more often than not, especially if you aren't a hotshot typist. One of the original ways of generating an FSK signal was to shift the transmitter down from mark to space by switching capacitance into the vfo circuit. Logging the mark frequency is natural for anyone using this method. There's a complication when this method is used on foreign news transmissions or other commercial signals which frequently send "upside-down," i.e., with mark being the lower frequency rf signal. In this case, one logs the higher rf signal (the space signal) and notes that the transmission is inverted.

Method	Frequency Logged
Mark	14800.2125 inverted
Lsb	14802.3375 inverted
Average	14800.000 inverted

Table 2. Examples of three of the methods commonly used to document RTTY frequencies. Taken from ADN, the East German News Agency, sending inverted, 66 wpm, 425 Hz shift, mark = 14799.788, space = 14800.2125.

This method, which we'll call the mark method for short, is the one I use when logging with an R390A. All frequencies mentioned in this article are mark frequencies.

The ARRL Lsb Method

If you use a sideband receiver to receive RTTY, this method should appeal to you. Simply set the receiver to lsb, tune for a mark tone of 2125 Hz, and log the frequency indicated on the receiver's dial. The RTTY frequencies listed in *QST* under "Operating Events" conform to this convention. This type of signal can be generated at the transmitter simply by driving the microphone input with clean audio tones of the same frequency meant to be recovered at the receiver.

The Imaginary Method

It makes sense to average folk to talk about RTTY being sent on the frequency halfway between the transmitted mark and space frequencies, i.e., on a frequency which is never actually sent. RTTY weather transmissions and news agencies are among the stations I've found to be using this method. With your receiver in CW mode, use the S-meter to tune for the strongest signal, then read the frequency from your dial. You'll have to set your bfo at different spots depending on the shift being used. This method can be inconvenient if the shift is unknown, if your bfo is uncalibrated, or if a sharp peak on the S-meter cannot be obtained due to a weak signal.

Examples of the three methods described are presented in Table 2. Formulas for converting from one method to another are given in Table 3.

What's To Be Printed?

Imagine that you have the ability to receive and print RTTY sent at any speed. (How this can be done with the help of a computer will be discussed.) You're ready to tune around the HF bands. What signals will you be able to print? See Table 4 for a representative list of signals heard during the last 18 months at my New Jersey QTH. Note that this list is just a sample of what's on the air. For those interested in obtaining a more comprehensive list, I strongly recommend Robert Grove's *Confidential Frequency List* (Gilfer Associates, Inc., Box 239, Park Ridge NJ 0765).

Unusual FSK Signals Heard

Roughly half of the FSK signals to be heard on the HF bands cannot be printed intelligibly on a straight Baudot teleprinter, no matter how you fiddle with the adjustments for wpm, shift, upright/inverted. The characteristics of a number of these signals are described in the following paragraphs. Sample frequencies are listed in Table 5.

Cyrillic

Cyrillic alphabet traffic is transmitted using a Baudot-like code. The transmissions in Table 5 listed as "Russian telegrams" are examples of this. On a normal Baudot machine, Cyrillic transmissions print as orderly lines of numbers and punctuation with an occasional "word" or two mixed in. Unlike western Baudot machines, which have two cases (letters and figures), Cyrillic machines have three cases – Latin, Russian, and figures – which are selected by the letters, blank, and figures functions, respectively. If you can cause

Mark = lsb - 2.125
Mark = avg. + ½ shift

Lsb = mark + 2.125
Lsb = avg. + ½ shift + 2.125

Avg. = mark - ½ shift
Avg. = lsb - ½ shift - 2.125

Table 3. Formulas for converting between the various methods of logging RTTY signals.

Table 4. Normal RTTY signals copied in New Jersey.

a letters shift on receipt of a blank, the garbage lines of figures case characters will be transformed into something almost resembling Slavic language words. I say almost because occasional words will have imbedded figures characters leading to words like BO4EK and HORO&EGO. Cyrillic machines need three cases to take care of the abundance of characters in the Cyrillic alphabet. The "4" in BO4EK is the best a normal machine can do for one of these third case characters.

Baudot Crypto

Encrypted Baudot, where code characters are substituted on an essentially random basis for plaintext characters and then transmitted, prints as garbage and, as such, is difficult to identify. Unless you have a way of qualifying the speed, sense (upright/inverted), and asynchronous nature of a signal, encrypted Baudot will look like any other garbage, although it will sound better than wrong-speed garbage while being printed.

Encrypted Baudot does not lend itself to being easily decoded. The transmitted characters do not have a one-to-one correspondence to the plaintext characters they represent. Each time a particular plaintext character is sent, it is encrypted as a different character selected on a random basis or on a pseudo-random basis derived from a complex mathematical formula known only to the receiving end. A string of test characters such as RYRYRYRY might be encrypted and sent as QAANFGRM, for example.

Some signals in Table 5 are listed as Baudot crypto. They were categorized as Baudot crypto because they exhibited the following attributes: 1) The received characters are individually all valid Baudot characters; that is, each has a start pulse, five data pulses and a stop pulse. 2) Each character received in a row exhibits these characteristics. 3) There are 32 possible individual characters in the 5-unit Baudot code.

Using the computer, a large sample of characters (e.g., 800) is received, and the occurrence of each of the possible 32 is counted. The counts are then examined. When analyzed this way, Baudot crypto exhibits an essentially flat character distribution, i.e., just about as many of any one character as of any other. Plaintext or text encoded by simple bit inversion or bit transposition (described later on) show relatively large counts on the characters corresponding to frequently sent characters (space, T, E) and low counts for infrequently sent characters.

Bit Inversion (Funny Cryptic Carrier)

A simple means of preventing the casual listener from reading one's traffic is to invert (mark becomes space and space becomes mark) one or more of the data bits in each character. When received on a normal machine, this type of transmission resembles Baudot crypto, but, upon inspection, it will not show the random character distribution of a highly encrypted code. The characters equivalent to the frequent spaces, Es, and Ts aren't hard to find, if a little elementary cryptanalysis is performed.

The result of bit inversion is the creation of a simple substitution cipher, which ought to appeal to amateur code breakers. The technically inclined code breaker need only get the five data bits of each character in parallel and experiment with inverting them in various combinations (only 32 possible) until he's printing plaintext. The bit inversion frequencies listed in Table 5 provide a 24 hour ready source which should be easy to copy anywhere in the USA. When text isn't being sent, a mark carrier is on the air. Hint: The number of bits

Table 5. Unusual RTTY signals heard in NJ.

inverted is always 2 or 3 (never 0, 1, 4 or 5), and the key is changed at 0000 hours GMT.

Here's an example: For the sake of discussion, let's number the data bits of the Baudot code 12345 (as in Table 1) and represent characters by binary numbers with mark represented by "1" and space by "0". The letter "E" is represented by 10000, "R" is 01010, etc. If bit inversion is being used on, let's say, bits 4 and 5, 10000 (E) becomes 10011 (B), 01010 (R) becomes 01001 (L), and 00010 (carriage return) becomes 00001 (T). Thus, if bits 4 and 5 are being inverted on a particular day, E will always print as B, R as L, carriage return as T, etc.

Synchronous Codes

We've talked about Baudot being an *asynchronous* code. By this we mean that, due to the presence of a start and stop pulse for every character, each character is self-synchronizing, and there is no other need for the transmitting and receiving ends to stay in synchronization.

There are numerous examples of signals on the air which show no evidence of start and stop pulses. In Table 5, examples of these signals are labeled as *synchronous.*

A study of various methods used for data communication between computers shows that there are many methods of synchronizing the transmitting and receiving ends of a synchronous communications line. In general, these methods have in common the presence of an accurate and stable timebase reference at each end, as well as some means of achieving initial synchronization and periodic resynchronization based on the content of the received signal. A normal Baudot machine will see random false start pulses in a synchronous signal and print garbage.

Other than Moore code, which is described further on, I haven't broken, or even identified, any of the synchronous codes listed in Table 5. The characteristics by which they are classified are simply frequency, shift, and bit size in ms. Computer analysis has shown that they do not have regularly occurring start and stop pulses for any size code, from a 6-unit code through a 14-unit code.

I would welcome information from readers having definite knowledge about any of these so-called synchronous codes.

Twinplex

Twinplex is a method of transmission in which the carrier is shifted among four discrete, closely spaced frequencies, allowing two distinct (but synchronized) RTTY channels to be simultaneously sent using one transmitter. It is designed such that reception of one of the channels is possible using a fairly standard TU.

Frequency	Notes
8899.970 kHz	Channel 1 space
8900.030 kHz	Channel 1 mark
8900.090 kHz	Channel 2 space
8900.150 kHz	Channel 2 mark
8900.210 kHz	Channel 3 space
8900.270 kHz	Channel 3 mark
8900.330 kHz	Channel 4 space
8900.390 kHz	Channel 4 mark

Table 6. Four channel FDM.

As an example, let's call the four frequencies A, B, C and D as follows:

A 8900.000 kHz;
B 8900.200 kHz;
C 8900.600 kHz;
D 8900.800 kHz.

We'd like to use these four frequencies, only one at a time, to send two synchronized TTY channels simultaneously. We design our transmitting scheme as follows:

1) At any point in time when channels 1 and 2 are both mark, send frequency A.
2) When channel 1 is mark and channel 2 is space, send frequency B.
3) When channel 1 is space and channel 2 is mark, send frequency C.
4) When channels 1 and 2 are both space, send frequency D.

This same relationship between the TTY channels and the transmitted frequency can be shown in tabular form:

Channel 1	M	M	S	S
Channel 2	M	S	M	S
Frequency Transmitted	A	B	C	D

If a twinplex signal is recognized as such (a good panadaptor is a help here), it should be possible to print channel 1 on a standard setup, provided the filters in the TU are not too sharp. You will have to tune so that your TU thinks it is seeing mark when either frequency A or frequency B is being transmitted, and seeing space when either frequency C or frequency D is being transmitted. Reference to the table above will show that setting up in this way will recover channel 1.

Commercial equipment, designed to receive twinplex, separates and recovers both channels simultaneously.

Frequency Division Multiplex (FDM)

Signals exist which are comprised of 4, 8, 16 or more separate RTTY channels sent simultaneously by the same transmitter. The available literature describes both amplitude modulated (pulsed CW) and frequency modulated (FSK) subcarriers with shifts of 30, 35, 42.5, 60 and 85 Hz. The equipment used commercially to separate such a signal into its constituent channels consists of a large, impressive rack of precision narrow band filters.

An example of a 4-channel FDM system using 120 Hz channel separation and FSK with 60 Hz shift per channel is shown in Table 6.

The twinplex signals described earlier can be considered as a special example of FDM. In a twinplex system, at any one instant in time, all the power is in only one of the four subcarriers. This advantage is counterbalanced by the requirement that the two channels of information be synchronized. The channels of a more conventional FDM system need not be synchronized, but the power is shared among the subcarriers, i.e., one subcarrier per channel is transmitted at any instant in time.

It's not unusual to receive signals which sound like a buzz saw gone berserk, and it's these that are allocated to the frequency division multiplex category in Table 5. Since I haven't yet printed clean copy on most of these signals or verified them in some other way, the FDM listings should not be considered 100% accurate.

Time Division Multiplex (TDM)

If two or more channels of information are separated in time by alternating the transmission of characters from each of the channels, time division multiplex results. Diplex transmission of Moore code, described further on, is an example of TDM.

For example, a 2 channel TDM system would alternate characters from each of two channels. Consider two messages punched on tapes: Channel 1, "READ KILOBAUD" and Channel 2, "ABCDEFGHIJKLM". The transmitter would alternately select a character from channel 1, then channel 2, then channel 1, resulting in a transmission of: "RAEBACDD EKFIGLHOIBJ AKULDM".

TDM/FDM

Time and frequency division multiplex techniques are sometimes combined into a single transmission. I've identified several examples of this to date – two channel FDM transmissions, each channel of which is sending diplex Moore code (TDM).

As an example, consider four TTY channels – A, B, C and D. Each, for simplicity's sake, is sending a message comprised of the channel's name repeated over and over, e.g., channel A's traffic is AAAAAA ..., channel B's traffic is BBBBBB.

This could be combined into a 2-channel (4-frequency) FDM system, the first channel of which is sending alternate characters from A and B (TDM), the second channel of which is sending characters from C and D (also TDM). See Table 7.

Frequency	Notes	Sending
8899.970	Channel AB space	ABABABAB
8900.030	Channel AB mark	
8900.090	Channel CD space	CDCDCDCD
8900.150	Channel CD mark	

Table 7. Four channels, TDM/FDM.

Moore (ARQ) Code

In 1963, the International Telecommunication Union published a unanimous recommendation that an automatic repetition on request (ARQ) code be used in situations where the use of a five-unit code would otherwise produce an intolerable error rate. The code recommended, called Moore code after its inventor, is an error-detecting synchronous code which represents each character in seven bits. For any character, three of the seven bits are always mark; the other four are space. This provides an error-detecting function, as well as the means of synchronization. The utility of the code is in full duplex (simultaneous two-way) situations. When one end detects a mutilated character, it momentarily interrupts its transmission of traffic and transmits a special character which initiates an ARQ cycle, that is, the retransmission of the last few characters from the other end.

Thirty-two of the 35 possible Moore code characters have a one-to-one correspondence to Baudot. Figures and letters case characters are paired the same in both codes. Indeed, standard 5-unit teleprinters are used in Moore systems, after appropriate code conversion, to create and print the traffic sent and received. See Tables 1 and 7 for the complete Baudot and Moore codes.

The three special Moore characters without Baudot equivalents are *idle alpha*, *idle beta*, and *signal I*. The idle characters are used as fillers; signal I is the special character used to request a

Table 8. Moore 7-unit code.

retransmission when a mutilated character has been received. The Moore signals I've received are comprised of two separate channels of information. Two different Baudot signals are translated to Moore and alternately sampled to produce a single FSK transmission. This is called diplex and results in a bit length of 11.67 ms or 163.38 ms per character pair. Characters from the two channels, called the A and B channels, are sent in alternate time slots, one A character, one B character, etc. To further complicate things (actually to help synchronize and to distinguish between the A and B channels), certain character positions are sent inverted, that is, 4 bits of mark and 3 of space. The pattern of inverted and uninverted characters repeats in cycles of 8 characters, 4 from channel A, 4 from channel B. Using upper case to represent uninverted characters, the two channels are combined in the following repetitive pattern: abaBABaB. This pattern repeats over and over, providing the method of distinguishing between channels and aiding in synchronization.

RUMORED SIGNALS

This section will present the characteristics of various signals which I've never heard on the air. I almost believe they're out there just waiting for the sunspots to come back. My faith is due to the number of people I've talked to who are convinced that they have received them, plus what I've been able to find in the literature.

Correspondence from readers who can provide actual time and frequencies of nonstandard RTTY signals, based on their personal listening or commercial experience, would be welcome.

ASCII

A popular nonsignal among hams is ASCII. Some are even convinced that most of the FSK they can't print is ASCII. I wish that were so. It's not. At least not where my antenna's been pointing. Using the computer, as will be described, I've analyzed hundreds of non-Baudot signals. I've never found any non-Baudot asynchronous code, let alone ASCII. They tell me Canadian amateurs are using it and North African news agencies, too. I'll keep looking.

Six-Unit Typesetter Code

Some South American countries are said to use a six-unit typesetter code on the air. This code is said to have a start pulse, five data bits, and that's it — no stop pulse.

High Speed Morse Code

High speed Morse code (around 300 wpm) is used in tactical situations to prevent interception and direction-finding by the enemy. Advantages are that simple equipment can be used at both ends. An operator records a message at normal speed, it is sent at high speed, recorded at high speed at the receiving end, played back at greatly reduced speed, and reduced to writing by a trained Morse operator. Despite the current disagreements between New Jersey and New York with respect to state income taxes, no high speed Morse has been received at my QTH.

Bit Transposition Baudot Cipher

Bit transposition is said to be used in private systems, similar in application to the bit inversion system described earlier. As with bit inversion, bit transposition requires that the five data bits of the Baudot character be obtained in parallel at both ends of the circuit. At the sending end, using a switchboard type arrangement, two to five of the data bits of the character are scrambled, according to a prearranged pattern, by moving them to a different position. At the receiving end, after obtaining the data bits of the character in parallel, the bits are unscrambled, utilizing a similar switchboard, then the character is printed.

Here's an example: As in the discussion of bit inversion presented earlier, let's number the data bits of the character 12345. A simple example of bit transposition would be for the sending end to transpose bits 1 and 5. Then 10000 (E) becomes 00001 (T), 01010 (R) remains unchanged, 01001 (L) becomes 11000 (A), and 01111 (V) becomes 11110 (K).

Character frequency distribution analysis of a bit transposition cipher would indicate a simple character substitution code. To date, computer analysis of scores of strange Baudot signals has not resulted in the identification of any bit transposition transmissions.

Bit transposition and bit inversion can be combined in a single system simply by the application of both techniques simultaneously. For our example, we'll invert bits 4 and 5 of each character and then, after inversion, we'll transpose bits 1 and 5.

Plaintext:
10000 (E)
01010 (R)
10011 (B)

Bits 4 and 5 inverted:
10011 (B)
01001 (L)
10000 (E)

Bits 1 and 5 transposed:
10011 (B)
11000 (A)
00001 (T)

If the procedures are reversed, that is, transposition first, then inversion, the results are entirely different.

Plaintext:
10000 (E)
01010 (R)
10011 (B)

Bits 1 and 5 transposed:
00001 (T)
01010 (R)
10011 (B)

Bits 4 and 5 inverted:
00010 (car. ret.)
01001 (L)
10000 (E)

Note that bit inversion, bit transposition, bit inversion followed by transposition, and bit transposition followed by inversion all have one thing in common – their use results in the creation of a simple character substitution cipher. As long as the key remains unchanged, each plaintext character will result in the same encoded character every time it is sent.

Although several sources have indicated that simultaneous bit transposition and inversion was in common use just several years ago, I haven't found any of it on the air since I've been listening.

I developed a computer program over the last two years to help in the reception and analysis of the many hundreds of RTTY signals I have found on the air. Without this computer program, the preceding article could not have been written. The computer provided the versatility necessary to quickly identify and print a variety of normal RTTY signals, as well as to analyze and classify the unusual signals.

This combination of the radio and computer hobbies is still in its infancy and would seem ready for growth. The number of RTTY signals on the air is increasing all the time; there are codes yet to be discovered, as well as a variety of codes already discovered, which need further analysis. Attacking this with a home computer is a computer game of sorts, a real time, real world computer game, which is at once very challenging and very satisfying. ■

RTTY Local Loop

-- perfect for beginners

About two years ago I saw an amateur radio teletype (RTTY) station on the air. That one look was all it took to fix in my mind that one day I would communicate from a keyboard instead of a mike.

Finally after several months of searching, I found my machine, a Model 15. It had been used in amateur service before and was in practically new condition.

Once I was home with the 15, the big job started – convincing the XYL that there was room in the spare bedroom I call a ham shack for this thing that it took two people to carry in. Fortunately, I have an understanding XYL, and, after some moving around of furniture, the 15 was set in position next to my operating table.

I plugged it in and turned the switch on. The motor came to life, and I was ready to see if this thing would really type. It wouldn't. I didn't know much about RTTY at that point, but I took a guess that it might have something to do with the two wires that were dangling down from the machine with phono plugs on the end.

It seemed that now was the time to pull out the back issues of *73*, which make up a large part of my reference library, and find out a little more about the 15 – like how do I make it type. After a few hours, I finally had it figured out. What I needed was a thing called a loop supply. It seemed that the RTTY needed dc as well as ac to run on.

I did more reading and looking for a loop supply that I could build and finally reached a conclusion. I would design and build the supply to fit my needs. My requirements were:

1. Ability to run the page printer from the keyboard (to make sure it will work).
2. Ability to run the page printer from a paper tape reader (T.D.). I was lucky to acquire one of these with the 15.
3. Ability to run a paper tape punch and the page printer at the same time. (What good is a tape reader without a tape punch?)
4. Use as few parts as possible. (I have a small junk box.)
5. All parts to be readily available. (Someone else might like to build one.)
6. Keep cost at a reasonable level. (My extra money is smaller than my junk box.)

A schematic diagram of the local loop supply that meets my requirements is shown in Fig. 1.

Unfortunately, the only parts I found in the parts box were the pilot lamp and the fuse holder, which is not much to start with. One of the requirements was that all parts be readily available, and a trip to the local Radio Shack found all the parts in stock. (The part numbers I used are listed in this article.)

The phono plug should not be grounded in this circuit. To overcome this problem, I first used one of the black Bakelite boxes that are so handy for small projects. This was a mistake. I found the mistake after about 10 minutes of test operation as the box slowly started melting around the resistors.

I made a second trip to town and back for a new box, this time a metal one with vents. I had no more problem with heat buildup. I insulated the jacks from the metal cabinet by using vinyl grommets.

If you do not run a type punch and T.D., you could leave out phono jacks J-3 and J-4. R-1 is a 2.5k Ohm, 10 W resistor, which gives the 60 mA required by my 15. (Since the required resistor wasn't available, I used my vast knowledge of electronics and came up with two 1k Ohm and one 500 Ohm resistors in series.)

So, I've got my 15 typing, and it's doing a good job. Now all I have to do is find out how to get it on the air. I believe it takes something called a converter and an AFSK oscillator. I have some ideas for the oscillator, and maybe I can tell you how it turns out later. ■

Parts List

Quantity	Description	Radio Shack Part Number
1	ac power cord	278-1255
1	fuse holder	270-739
1	fuse (1 Amp)	270-1273
1	pilot lamp	272-703
1	metal cabinet 4" x 2½" x 6"	270-252
1	push/on—push/off switch	275-1551
1	full-wave bridge rectifier (4 Amp, 450 volt)	276-1172
1	electrolytic capacitor (20 uF, 450 volt)	272-103
2	10 Watt power resistors (1000 Ohm)	271-140
1	10 Watt power resistor (500 Ohm)	271-138
4	phone jacks 2 conductor (closed circuit type)	274-255

Try the RTTY Reader

-- computer display goes ham!

Only a handful of area RTTY enthusiasts could be convinced to come up to two meters from the HF bands. That was until the Central Pennsylvania Repeater Association (CPRA) established its WR3ACO RTTY machine*. Now, with autostart a must, a Model 15 printer has become a "paper hungry monster," with the machine running continuously from early afternoon until well after midnight. In the Harrisburg PA area, your only defense against a daily reading load approaching the *New York Times* is to turn the thing off, and miss all the good stuff, or record everything on cassette tape.

In my search for noiseless RTTY, I came upon a truly unique subassembly, designed and built by Micon Industries in Oakland CA.[1] The unit is an extra bright alphanumeric display module designated as the #932. The module is the heart of their personal computer terminal called the Pocket-term. The display consists of a single line of text with 32 alphanumeric character positions. The letters are the size of a display on a typical hand-held calculator, but the display is 6.4 inches in length. The LED module can be set up to display parallel ASCII or Baudot information simply by grounding one pin of its 16 pin minidip interface plug. Further, information may be shown in a variety of ways — typewriter mode with cursor reset, clear, and backspace, or in a walking mode similar to the Times Square news and weather display. Another mode, burst mode, may also be used ... for the more enthusiastic builder.

Therefore, if a mother board were designed into which the display module could be plugged, providing a simple RTTY terminal unit, a UART for converting serial Baudot to parallel, power supplies and some associated interface circuitry so that the #932 module could be used without modification, a desktop RTTY reader would be the result. As an added bonus, the unit, when completed, would be hardly bigger than a carton of cigarettes.

A letter to Micon Industries brought the display to my door in less than two weeks. The associated data sheets left much to be desired, but the basic data furnished was sufficient to continue with the project. Table 1 shows the terminations for the 16 pin male DIP plug which is furnished with the module along with about 8 inches of ribbon cable.

*WR3ACO RTTY rptr (ns). In: 147.975 MHz; out: 147.375 MHz.

Pin #	Function
1	Ground
2	-12 volts dc
3	End of line (positive edge indicates start of new line)
4	Memory clock 4 kHz
5	Read/Write
6	LTRS (low); FIGS (high) . . . also 6th bit in ASCII
7	05
8	04
9	03 DATA IN . . . five bits for Baudot, 6 bits for ASCII
10	02 with pin 11 being the least significant bit.
11	01
12	An LED indicator which needs only +5 volts through a 470 Ohm res.
13	Scan clock . . . connect to pin 4
14	Clock Inhibit "0" enable
15	Baudot (high); ASCII bring low
16	+5 volt logic supply

Table 1. Pin connections for the Micon #932 display module.

Circuit Interface

The scan clock and the memory clock are both driven from the same simple CMOS oscillator. The clock must run anywhere from 3 kHz to 5 kHz and is not critical. The scan clock is interrupted by the use of the clock inhibit (pin 14 for use in the walking mode, in this application). Only one 8-input NAND gate is required to decode the FIGS LTRS input. By recognizing the high condition of Baudot data bits 01, 02, 04, and 05 and pin 19 of the UART, we can then use data bit 03 to tell the display module the shift code for FIGS or LTRS.

This arrangement, when data bits and pin 19 of the UART are in the true state, allows the flip-flop to sample bit 03. Almost as an afterthought, the same logic was applied to decode uppercase "S" or bells . . . you just gotta have bells. One half of the CD4013 D type flip-flop is clocked similarly, but this time detecting a true condition on the 5 data lines (three inverters are required) and, once again, the high condition on pin 19 of the UART. An all conditions true for upper case "S" triggers the other half of the CD4013, which is set up as a one-shot multivibrator. Given that the single Baudot code for a bell is approximately 160 ms, the RC network on the one-shot stretches this pulse length to about 250 ms. This pulse then directly triggers pin 4 of an NE555 timer, set up in an oscillator configuration, which drives a speaker directly from pin 3 through a capacitor. This oscillator is set up to provide a fairly good volume without controls. But volume can be adjusted to suit by shunting the output more than that shown. All unused CMOS inputs must be grounded or

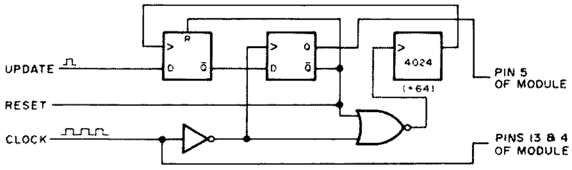

Fig. 1. Typewriter mode.

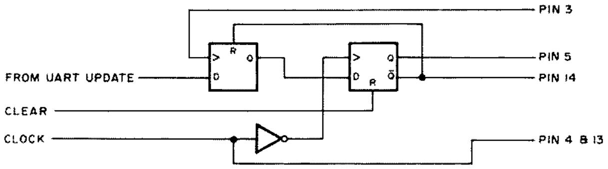

Fig. 2. Walking mode. Data bits must all be low when clear is activated.

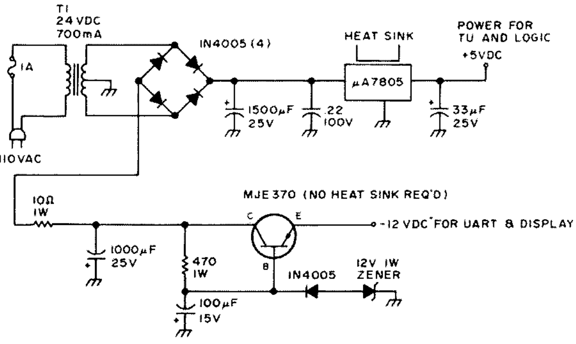

Fig. 3. RTTY reader supply. 5 – 1N4005 diodes; 1 – 1500 uF 25 V; 1 – .22 uF 100 V; 1 – 33 uF 25 V; 1 – UA7805/MC7805; 1 – xfmr 24 V ac 700 mA, Stancur; 1 – MJE370; 1 – 12 volt zener; 1 – 470 Ω 1 W resistor; 1 – 10 Ω 1 W resistor; 1 – 1000 uF 25 V; 1 – 100 uF 15 V.

tied to other inputs to prevent self-oscillation.

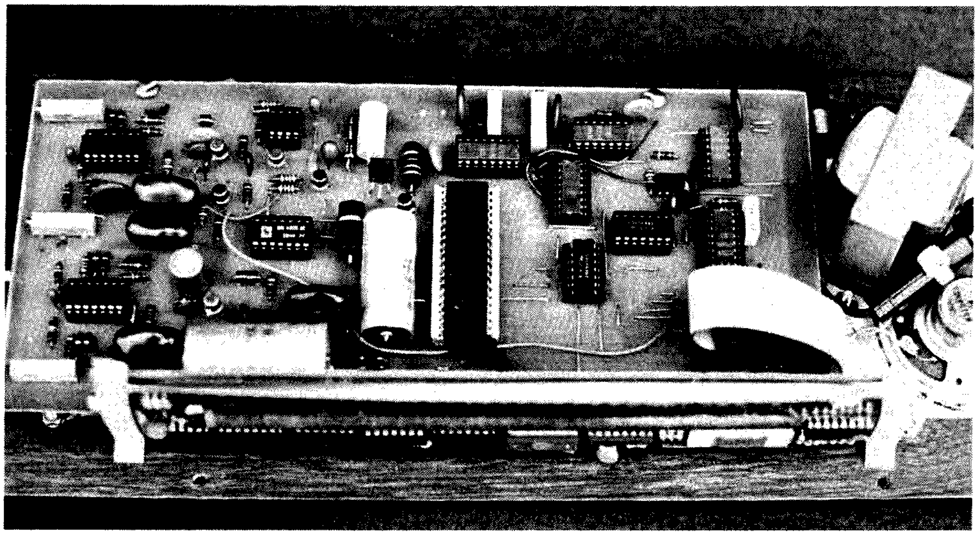
Two clocks are required to operate the display. The UART clock should be set to 727 Hz for 60 wpm operation. The clock speed control will adjust to any speed desired, however. If the fixed resistor is carbon film, then the variable control can be any cheap composition type, while still maintaining greater than 1% frequency tolerance. The capacitor should be mylar or silver mica. The display clock, on the other hand, is not critical and can have a 20% tolerance. Therefore, composition resistors and a disc capacitor may be used. No adjustment of this clock should be necessary. The CD4049 hex inverter is used for both clocks, as the outputs are buffered as necessary.

As a special note, additional information is presented for other applications for the display module. A strapping option on the board allows the use of EBCDIC. The display can accept data rates of up to 250 characters per second – too fast to read but not to photograph. Higher speed versions can be furnished by Micon that will display up to 1000 characters per second. Power requirements for the RTTY reader are +5 volt logic at about 600 mA and a scant 20 mA at -12 volts. Since the display module and the UART both require -12 volts, no other voltages are required. Each character of the multiplexed array emits about 500 microcandles of light. It's almost too bright. Only one character position is being illuminated at any one time, and the display appears to the eye as average. Actually, each LED is being strobed 32 times brighter than its average appearance, but is run on a 1 out of 32 duty cycle. The 4 kHz clock frequency produces a scan frequency of 125 Hz. Any scan frequency below 90 Hz may cause the display to flicker.

The negative edge of the clock applied to pin 13 (see Table 1) will advance the scan logic and character position to the right. On the negative edge of the clock applied to pin 4, the memory will select the segments to be lighted for the next character. If pins 4 and 13 are tied together, as they are in this application, then the display (with no new data entered) will appear static. A positive edge is output from pin 3 every time a scan starts out from the left of the display. This pulse is used to synchronize character positioning for the updates. For example, if, in typewriter mode, you wish to place a new character in position 14 (from the left of the display), wait until you receive a positive edge from pin 3, and then count 13 negative edges of the scan and memory clock. Now the read/write line on pin 5 should be pulled low, and, during the next positive edge of the memory clock, the character on the input pins will be loaded to memory. Pin 5 should be returned high on the next negative edge.

In the project described here, the walking mode is used. Here update occurs coincident with the positive edge of pin 3. This causes the new character to appear in the left-most position. All characters are then shifted to the left, rotating the new character to the right. In order to move characters to the left, the scan clock needs to skip one cycle in relation to the memory clock. Conversely, skipping a memory clock cycle in relation to the scan clock causes all the characters to advance in the other direction. In the walking mode, pins 4 and 13 can still be tied together, and pin 14, the scan clock inhibit, can be used to inhibit scan cycles. See Figs. 1 and 2.

Pin 12 on the module connector controls a bright spot LED on the left end of the display. This may be used as an indicator for anything. Here we use it as a tuning LED for mark (on) and space



(off) for tuning in signals. In my version of the RTTY reader, there are absolutely no external controls – switches or knobs – not because we don't like them, but none were necessary. The TU to be described has such a wide dynamic range with self-limiting that no control was required. No manual reset was required, either, because of the electronic autostart control system included. The only wires coming out of the box, then, are the ac power cord and an audio input phono connector. When using the LED indicator, be sure to current limit the LED with a 470 Ohm resistor, if using a 5 volt supply.

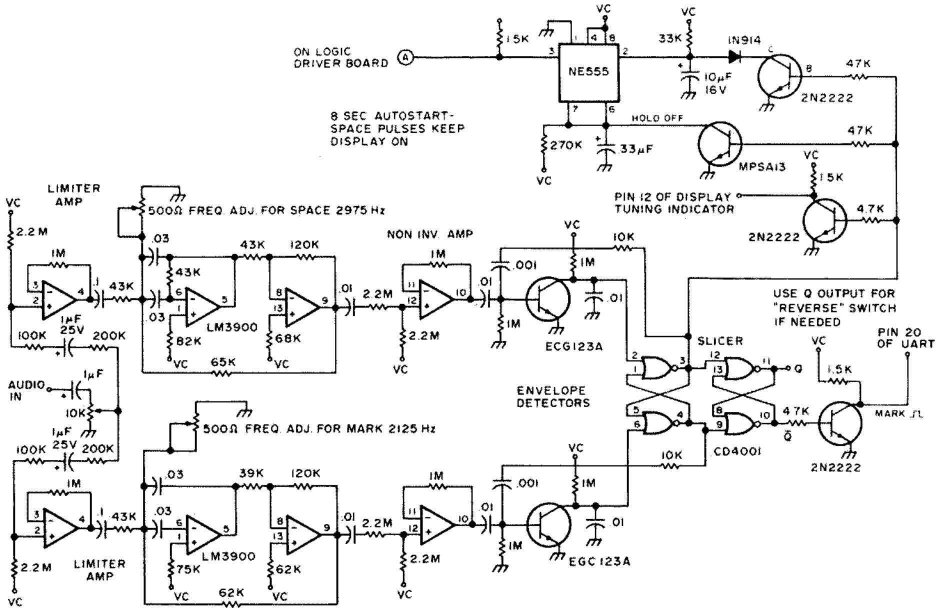


Fig. 4. RTTY reader terminal unit. Vc is +5 V dc. (Pin 14 is Vc, pin 7 is gnd.) 2 – 500 Ω type 43 trimpots, James; 1 – 10k type 43 trimpot, James; all resistors are ¼ Watt 10%/5%.

Construction of the RTTY Reader

Construction of the RTTY reader mother board, which included TU, autostart, power supplies, and UART, is easily accomplished with a single-sided PC board included. Construction is begun with the two power supplies. A single 24 volt power transformer is used with center tap to ground. The resulting plus 12 volt supply is used in the 5 volt logic regulator, and the minus 12 volt supply is regulated for both the UART and the display module. As can be seen, there are many over-board power supply jumpers to provide power up of each individual stage or functional section of the board. This aids stage by stage testing of the unit. Complete stage by stage testing is a must to avoid errors which would destroy costly CMOS components.

The power supply is a straightforward design with an MC7805 or equivalent used for the 5 volt regulator chip. Adequate +5 volt power supply bypassing is provided throughout by the liberal use of .1 uF capacitors at the inputs of the various stages.

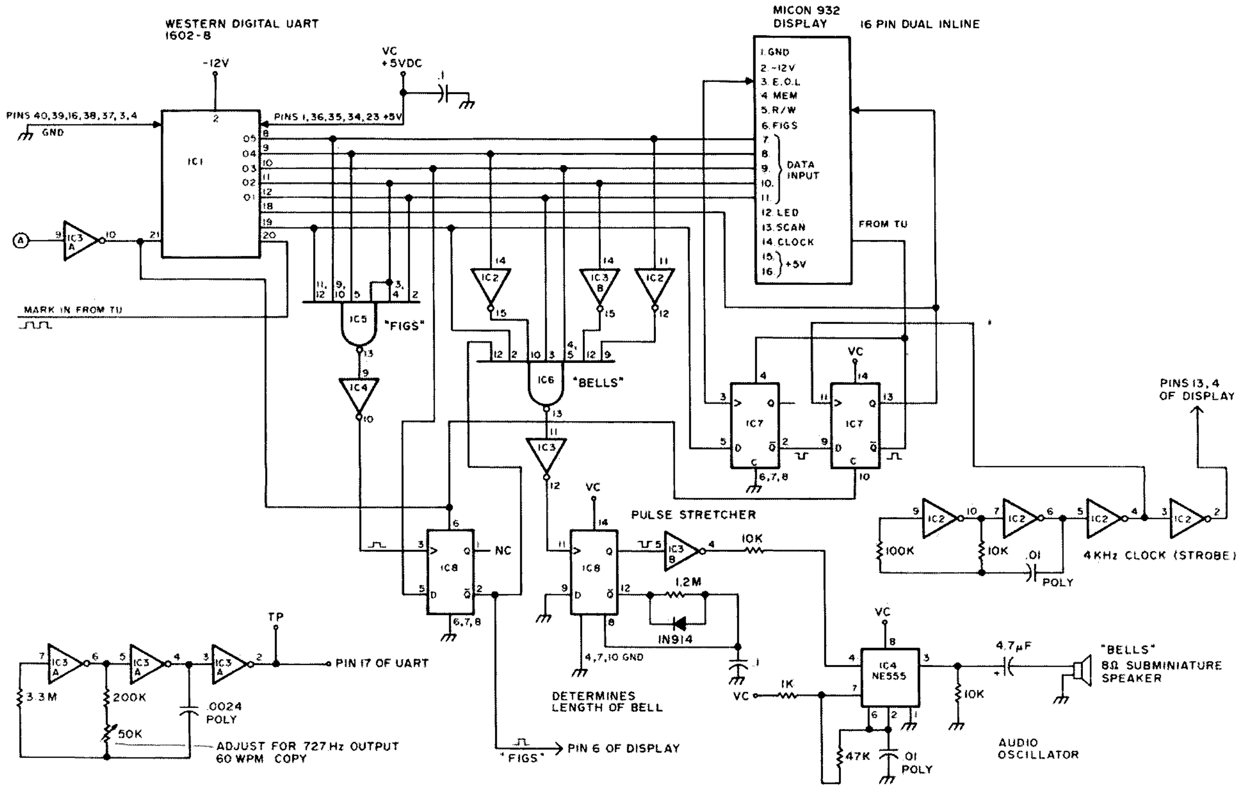

Fig. 5. Logic display driver. 1 – IC1 1602B UART, Tri-Tek; 3 – IC2, 3 CD4049; 1 – IC4 NE555; 2 – IC5, 6 CD4068B; 2 – IC7, 8 CD4013; 1 – 50k type 43 trimpot, James; all resistors ¼ Watt 5%.

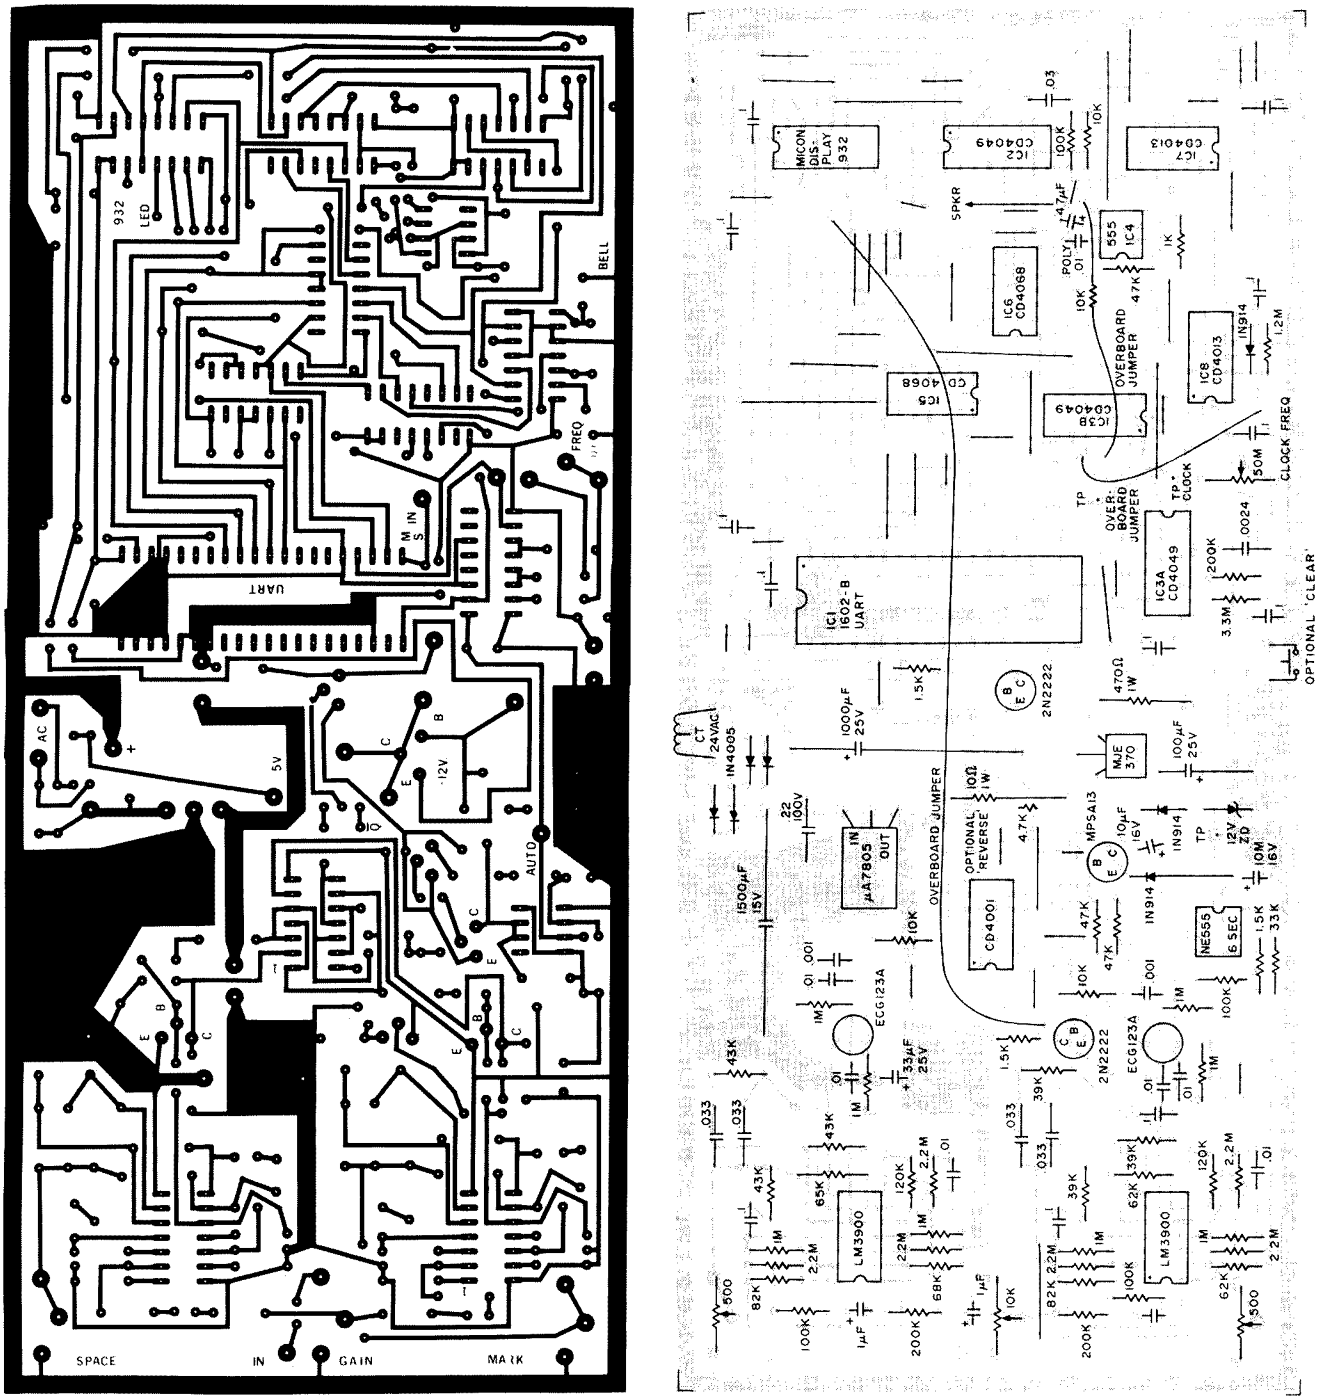

Fig. 6. PC board. Component layout shown from bottom.

The -12 volt supply requires no heat sink because the MJE370 current demand is well under 50 mA. The 5 volt supply will require heat sinking in addition to the large foil on the board for this purpose, because, with all the characters going on the screen, thermal shutdown will occur without sinking. The mother board was mounted on ¼ inch standoff spacers, and the 7805 was bolted directly to the aluminum bottom plate of the chassis. This provided more than enough sinking for cool operation and for continuous duty. Remember, the -12 volt supply is negative and the filter capacitor's polarity must be reversed. See Fig. 3.

RTTY Terminal Unit

The all-purpose mother board also provides a simple, yet very effective, RTTY terminal unit, with many desirable features. Mark and space tones are easily adjusted with a simple pot. The terminal unit described makes use of the LM3900 quad op amp.

This unique component consists of four individual operational amplifiers in a standard 14 pin dual in-line case. The power supplied to this component can be anything between +5 volts up to 18 volts. See Fig. 4. Audio from the receiver is brought to the board through a 1 uF capacitor and volume control. The audio path is divided and directed to two sections of the op amp, which are limiting non-inverting amplifiers. These amplifiers in turn

drive a two stage bandpass filter with a gain of 15 and a Q of about 25. A slight frequency variation of the bandpass is possible by using the 500 Ohm variable resistor employed in the feedback circuit of each bandpass filter. The values shown for each filter were selected for a mark tone of 2125 and a space tone of 2975 Hz, respectively. The resistors shown in the feedback path will provide for optimum gain and Q but are not that critical. Determination of these components was obtained from the *Op Amp Cookbook*[2]. Other space tones, such as 2295, may be substituted and are within the practical range of the given component values. However, not inserting more exacting parts in the feedback circuits causes some gain and some Q loss.

The outputs of both filters are once again amplified in a non-inverting final stage of the LM3900. Tuning the active filters consists of driving the input from an audio source of the proper frequency and turning the 500 Ohm pot on each feedback network for maximum sine wave output at pin 10 of the op amp with a simple ac scope.

The MPS 2925 (ECG 123A) transistors convert the audio peaks to CMOS driving pulses in an envelope detector configuration. The two detectors then drive alternately a basic RS flip-flop, which follows the mark-space transition. The output is buffered again, resulting in a Q and Q-bar output of IC1, which then drives a low power keying transistor used to provide RTTY serial input to the UART. A reverse switch may be installed at this point if desired.

Autostart

The autostart function utilizes a small portion of rectified audio from the output of the 2125 amplifier. This audio delay starts (about 3 seconds) an NE555 timer, which is held from timing out by the use of space tones to bleed off the timing capacitor. Since the output of the NE555 at pin 3 is held high with valid RTTY only, the output is coupled to pin 21 of the UART. This supplies enable high to the UART and supplies a clear to the update flip-flop, causing the recirculate line to go low. This will fill the display with the characters present on the data lines. Since the UART has been reset, the data lines will all be "0", thereby filling the display with blanks. The NE555 also provides a clear pulse to the FIGS/LTRS FF, which always comes up in LTRS. Reset of this line occurs in three ways – autostart call-up, manual pushbutton (if desired), and power up.

A miniature noiseless RTTY terminal, without the rigid design specifications and high cost of a video/CRT system, is the result of this project. Other applications could include an automatic Morse code reader display or a portable "advertising" display using prerecorded information on a tape recorder. Perhaps the more industrious ham gear manufacturers will provide a similar module in their new receiver models, which decode Morse, all speed RTTY, and ASCII at the flick of a panel switch.

We hope you will have as much fun with this project as we did in building and showing it off. Technical questions with regard to the display module should be directed to Mike, and TU interface and mother board questions to W3JJU. Good viewing. ■

from page 16

FRIVOLOUS PETITIONS

The FCC says on the one hand that it doesn't hear enough from amateurs about the rules they want. On the other, they complain about the many silly petitions being sent in.

The ARRL has caused a lot of this trouble. In order to appear to be the "representative" of amateurs, the League works hard to convince amateurs that they should tell their directors about their reactions to rule changes rather than "bother" the FCC. Amateurs find that this is a sure way to not be heard at all, so they react with apathy . . . what can one person do? . . . etc.

The League would like it best if they were the only group entering amateur rule change petitions to the FCC . . . and the only group commenting on dockets proposed by the FCC. This is the thrust of just about everything you read in *QST* and hear from directors when (and if) they visit your club.

In many cases, rule making petitions are submitted to the FCC as a way of tackling some immediate problem. By the time the FCC has come to grips with the petition, several years later, the whole matter is often irrelevant. Unfortunately, this doesn't deter the FCC from making a big deal out of it and coming forth with some fascinating rule proposals.

Also contributing to amateur apathy in the matter of FCC dockets is the reaction of the ham magazines. *QST* generally provides a dry and boring report in very fine print. *Ham Radio*, in refusing to even mention the subject, indicates that it is of no importance. *CQ* does the same in almost all cases. I try to see that FCC dockets are as well covered and discussed as possible in *73*, but we're only one magazine out of four, so the general attitude is that someone else should worry about these things . . . they are of no real significance.

Perhaps you've noticed that very few of the petitions submitted to the FCC for rule making have been published in any of the ham magazines. They are not generally published in *73* because we haven't been getting copies of them – not even the more interesting ones. If the person submitting the petition doesn't think enough of it to send us a copy, how serious can he be about it? The FCC doesn't have the men or money to make copies of all petitions and send them to the magazines.

One possible way to keep the FCC from wasting a lot of time trying to cope with frivolous petitions would be to have a committee of interested amateurs look them over and recommend action on the valuable changes. This would act somewhat like a congressional committee. I'd be glad to help with such a committee and I'm sure we could get some other fellows to help.

The more amateurs can do for themselves, the freer amateur radio will be to encourage amateurs to do the things our "service" has been designated for: pioneering and inventing, public service, etc.

UNWELCOME VISITORS

There seems to be a lot of fretting going around that the sale of two meter transceivers by Sears, the recent promotion by Ancomm of their two meter set in CB magazines, and NRI ads for a two meter transceiver as part of their educational package might result in a lot of CBers turning up on two.

The thinking is that since little or no license is required for CB operation . . . and since a lot of CBers are used to ignoring the rules . . . and since there are perhaps 200,000 or so CBers operating in the "channels" above number 40, what is to stop them from claim-jumping into two meters and showing up on our repeaters?

Maybe. If this is starting to happen, I'd like to hear about it. I don't doubt that a few CBers with more brass than others will make a try at getting on two without a ham ticket . . . but I think that amateurs will figure out how to put a stop to it in short order. I'd like to hear about any experiences along this line . . . and think this would be of interest to all readers.

This is something we have to come to grips with quickly . . . for the most part, we are on our own. Don't think that the FCC is going to send a van out to track down a pirate for you and put him out of business. The amateur service is billed as self-policing, and this will have to be it for any practical matters. Repeater groups should plan ahead what they would do if a pirate comes aboard, and have the routine worked out ahead of time.

Most fellows who give piracy a try will probably get discouraged quickly if your group is able to respond and convince him that you are not going to put up with any non-licensed operation. I suspect that a "polite, but firm" approach may be the best. If you get abusive, then you may create a challenge for the chap to harass you with kerchunking and bad language. Explain the facts of life to him . . . invite him to come to the club and take a course so he can get his ticket

Organize Your RTTY Pix

-- a sweet tooth is desirable

Ken Mabie W2PSU
446 Rochelle Ave.
Rochelle Park NJ 07662

Fig. 1. The author and two methods of storing paper tape pix. The choice should be obvious!

There are many interesting aspects of amateur radio teletype. Some RTTY operators are into DX, others have computerized stations, and still others collect RTTY art, or "pix." I am a member of the latter category, and can usually be found exchanging pictures with other enthusiasts on Saturday morning.

Some hams may not be familiar with the technique of transmitting pictures with teletype. Let me explain, to provide insight into the associated problems. RTTY pictures are formed by typing standard characters over a "pattern," which is the picture being generated. Shading and detail is produced by using different character groups. It usually takes several attempts to make a good picture, as experimentation is required to form the correct shades. All of this "editing" is performed on the previous attempt until a perfect work of art is produced! In order to work on the previous partial picture, some method of saving it is required. The medium most commonly used is paper tape – yards of paper tape. Most RTTY machines have a paper tape punch incorporated into the keyboard system, so a tape is punched along with the character being printed. This tape can be read at a later date with a "tape distributor" (TD). Thus, the end result of the editing process is a new paper tape with the complete picture. Some detailed pix use overlining to achieve contrast, which requires many feet of tape. I

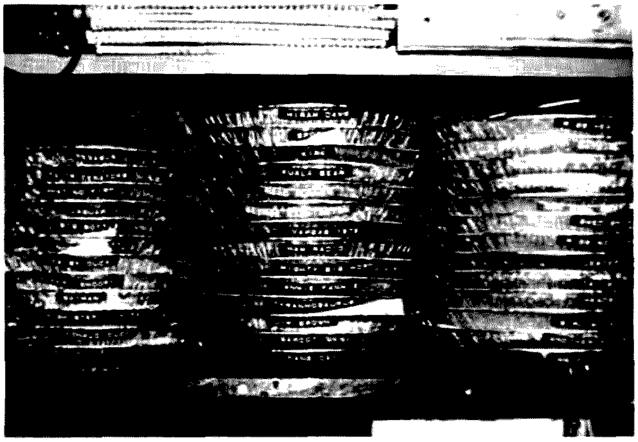

Fig. 2. Paper tape library. The titles of the pix are cemented on the outside of the plates for easy reference. The plates are stacked to conserve space.

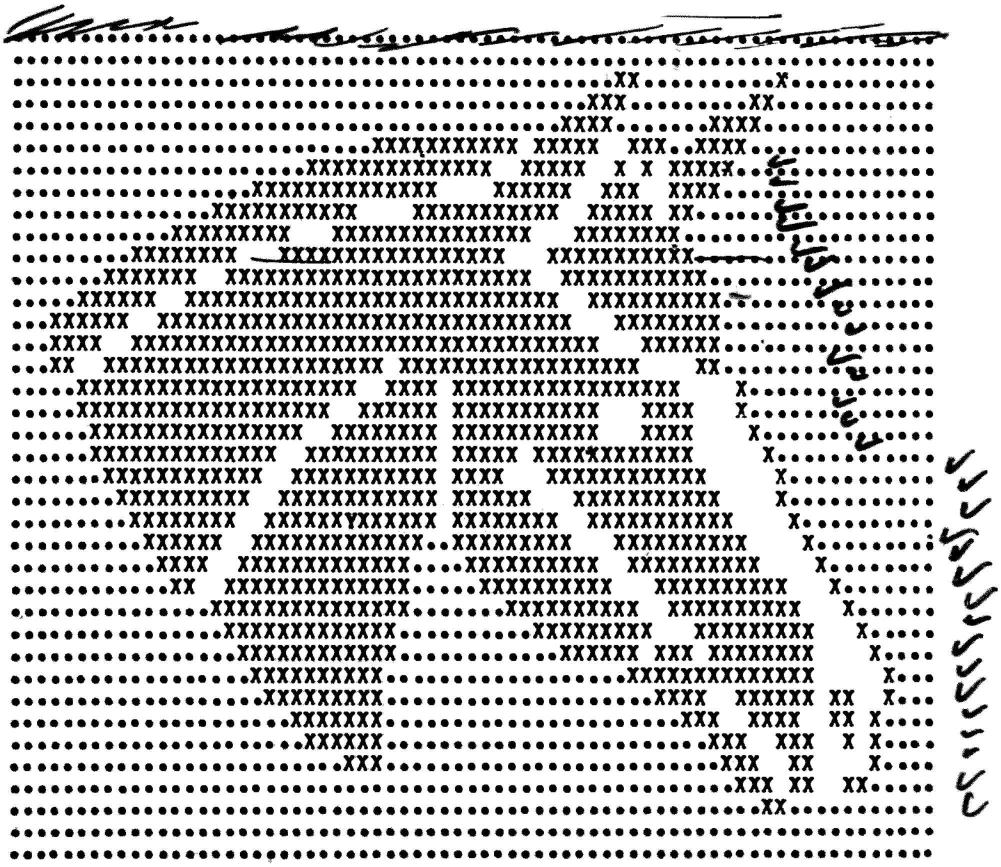
have several pictures which are represented by several hundred feet of tape and take over an hour to print! Pictures are received off the air in similar fashion. In order to save the picture for your own collection, it is necessary to use tape or magnetic cassettes. When using paper tape, a device known as a reperforator is employed to punch the tape while the picture is being printed off the air. This tape is usually edited to correct transmission "hits," and then is saved for later use. This is where the problem develops — what does one do with mounds of paper tape as the pix library expands?

Originally, I saved my pix by winding the tapes in the classic military "figure eight," and hung them around the shack. However, this posed two problems: (1) it didn't take long until every available inch of wall space was covered with little rolls of tape, and (2) it was difficult to tell which tape was which. My initial solution involved storing the tapes in shoe boxes, with the "table of contents" on top. Soon, however, my floor began to fill up, and who can afford new shoes every week just to get the boxes? A cure to the tape storage problem was definitely required.



THE DERBY WINNER

Typical RTTY art.

The ultimate cure presented itself one evening as I watched my wife discard a pile of aluminum pie plates. (Her father owns a bakery, and pie plates are a fact of life.) It seemed obvious that a lot of tape could be stored in a flat plate, when the tape was rolled in a cylinder, like film in a 35mm cassette! Sure enough, my longest tape fit neatly in a pie plate when it was rolled up! Never again will those plates end up in the trash.

My method is simple: I simply roll the pix tape into a cylinder, and secure it with a rubber band. The pie plate can be labeled on the outside, eliminating confusion. Another advantage to the plate method is that successive pie plates can be stacked, thus conserving additional space. See Fig. 1 for a before and after example of tape storage. Fig. 2 provides a close look at a shelf holding my pix library.

That's it! I cannot think of any easier method of storing valuable RTTY art in limited space. The only problem with the pie plate method is obtaining a large quantity of plates. Possibly your friends can save them; if not, be prepared to join Weight Watchers, as your diet may become overloaded with cherry pie! So go after those pix, and look for me on 20 meters any Saturday — I'll be ready to copy any new works of art. ■

New Products

from page 15

With the new P(*)M gooseneck plug, mike and gooseneck stem can be quickly, easily disconnected from the stationary receptacle and stored away. The potential of damage or theft of the gooseneck and microphone is eliminated.

Also, the easy connect-disconnect feature permits ready use of microphone and gooseneck in different locations.

The new plug, available in a choice of 3, 4, and 5 pins, has heavy brass housing and satin nickel finish, 5/8-27 external thread on one end for securing plug to bottom of the gooseneck, features exclusive captive design insert screw, and "ground terminal" is electrically integral with plug housing for sure grounding.

P(*)M plugs mate with Switchcraft "Q-G" audio receptacles, new QGP (quick ground professional), and other connectors with compatible contact configurations.

For details, write for New Product Bulletin No. 308, Sales Dept., *Switchcraft, Inc., 5555 No. Elston Ave., Chicago IL 60630.*

*Choice of 3, 4, or 5 pin contacts.

NEW ACCESSORIES FROM YAESU

Yaesu Electronics Corporation of Paramount, California, announces the availability of two accessory items to its product line: a digital LEO readout for the FT-221, FT-221R two meter all mode transceiver, and high quality headphones for all communications requirements, commercial or amateur.

The YC-221 LED frequency readout simply plugs into the FT-221 series. A simple minor modification needs to be made to some of the early transceivers and full instructions are given in the YC-221 manual. The frequency readout is in seven digits, covering 144 to 148 MHz in one half inch LEDs. Amateur net price is $119.

The YH-55 headphones are low impedance types with cushioned type earpads, and frequency response tailored for voice communications. Amateur net price is S15. Both products are now available at all authorized Yaesu dealers. *Yaesu Electronics Corporation, 15954 Downey Ave., P.O. Box 498, Paramount CA 90723.*

Build A RTTY Message Generator

-- it's programmable!

This project is similar to some of the CW keyers with memory, where a CW message can be put in memory to be recalled later. There is one major difference – this one is for RTTY. It will store as many individual messages as desired, but is limited to 1024 characters. A CQ message could be message 1, and several contest reports might be entered as later messages. All that is necessary to operate the contest is to press RUN, watch your machine send "CQ contest DE WB9XXX," and come to a halt. You then listen for a call, and, if you get one, enter the call on the keyboard and press RUN again. The machine will then send message 2. If message 5 was desired instead of 2, its starting address is selected on 3 rotary switches and loaded. Just press RUN and it will now send message 5.

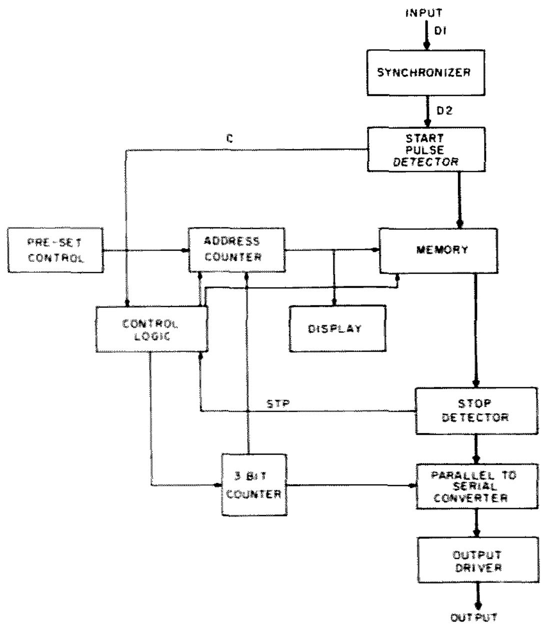

Fig. 1. Block diagram.

The RTTY message generator is intended for the person just getting started in RTTY or one who has been on the air on RTTY without any type of digital control. I do not claim that this system can outperform a computer, but it does not deplete the savings account as much, either. You cannot change its basic function by changing a program, but you can change its message content and output format. What about cost? True, the 8008 micro is under $20 now, but it requires other ICs for support. This project uses standard TTLs and five MOS static RAMs, which, at last check, were selling for $1.05 each. I built the system mostly from junk box parts, but, even if you bought everything new (excluding packaging), it should cost less than $25.

As presented here, the system will do the following: In input mode, and after the RUN button is depressed, the unit will record a serial TTY input which is TTL compatible (mark = 1, space = 0) at any speed up to 100 or 60 wpm. A second message may now be typed in. Note and jot down the address from the 3½ digit LED display first, so, when you want to recall message 2, you will know where it is. This can be continued until memory is full. (There is a limit of 1024 characters for this unit, but that could easily be expanded.)

Let's say you have 5 messages in memory, and they are stored as in Table 1. If the operator wants to send CQ at memory location 0000, he can press RESET, then press RUN. The message will be outputted in serial format at 60 or 100 wpm (as selected) and will stop at location 0136. If the second message is to be transmitted next, all that has to be done is to press RUN. If the operator wishes

Message #	Address (octal)	Content
1	0000	CQ
2	0136	QTH, name
3	0224	Station, ant, rig
4	0506	RTTY art
5	1212	CQ

Table 1.

to skip to message 4, he must change the address to 0506, then press RUN. The address can be changed to any desired value by selecting that value on 3 rotary switches and one toggle switch and then pressing the LOAD button. The address is inputted and read out on the LEDs in base 8. This octal input is converted to a ten bit binary number required by the RAM address inputs by a diode matrix. Octal is used because it would be difficult and confusing to attempt to load in a ten bit binary number with ten toggle switches, not to mention the operator's ability to remember a ten bit binary number. The BLANK key on the Teletype keyboard is used as a stop command when printing data from memory. So any number of separate messages can be started and printed by, first, loading in the address where that particular message is known to start, and second, depressing the RUN button. This message will be typed out at 60 or 100 wpm, and the printer will automatically stop at the end of the message.

How It Works

The signal flow through the unit is represented by the heavy black line in the block diagram in Fig. 1. The input signal from the machine is labeled as D1. It is generated by the keyboard switches shorting pin 2 of latch U18A to ground during a space and opening the path to ground during a mark. See Fig. 2(a). A resistor going from pin 2 to Vcc keeps it a logical 1 during mark. Mark and space are terms used in describing, respectively, whether current is flowing in the selector magnets of the machine, or it is not.

The Baudot code used with most Teletype machines consists of seven bits. These seven bits are sent serially over one line. The first bit is called the start bit and is always a space (logical low in this circuit). The next five are the five data bits of the code and can be high or low depending on which letter is being sent. The last is a stop bit and is always a mark or high. The start bit tells the receiving machine to get ready to receive the data bits. The stop bit is used to allow the machine to come to a rest before the next letter is sent. At 60 wpm all pulses are 22 milliseconds in length, except the stop pulse, which is 31 milliseconds long. Since D1 goes low at the instant a key on the keyboard is depressed, it must be synchronized with the clock of the system. This means the new synchronized signal D2 changes levels only at the same time that the clock goes from a low to a high. Referring to Fig. 2(a), the clock is applied to a monostable multivibrator U16. The timing resistor and capacitor produce a short pulse at pin 6. This is applied to the latch U18A. This latch stores the present state of the incoming data and is updated each clock pulse (every 11 ms).

As can be seen from the block diagram, D2 is now applied to the start pulse detector and to memory. The start pulse detector does just what its name implies – it detects a start pulse coming in, starts a timing sequence to control the counters, and creates write pulses, which are sent to each RAM at the time when its data bit should be on D2. The output of this circuit is called $\overline{C}$. It is normally low when data is coming in and for short times between each letter. When D2 goes low, $\overline{C}$ goes high and remains high for 14 clock pulses. It returns low during the middle of the incoming character's stop pulse.

Referring to Fig. 2(c), this

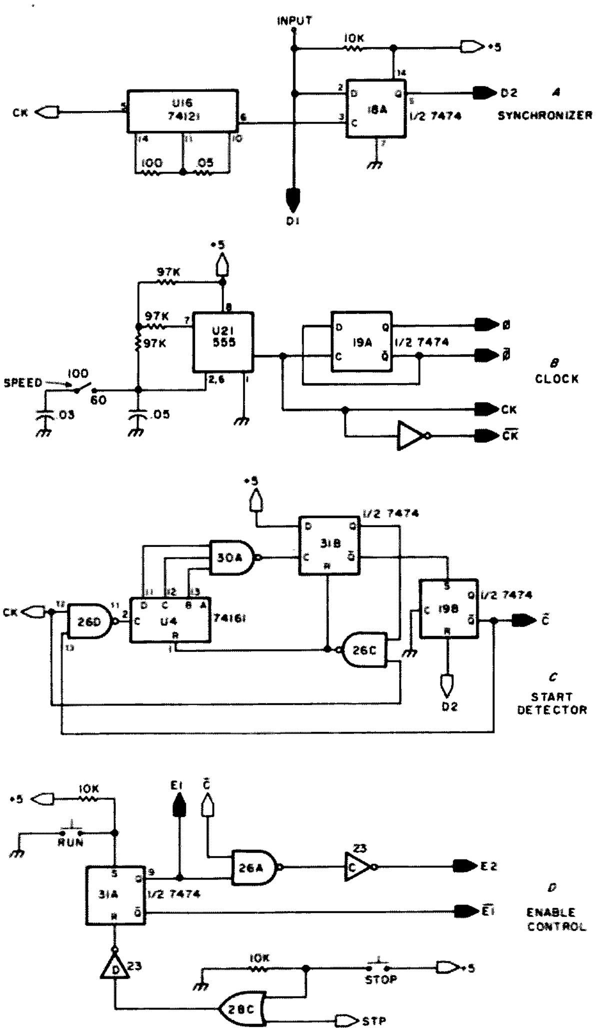

Fig. 2. a) Synchronizer; b) Clock; c) Start detector; d) Enable control.

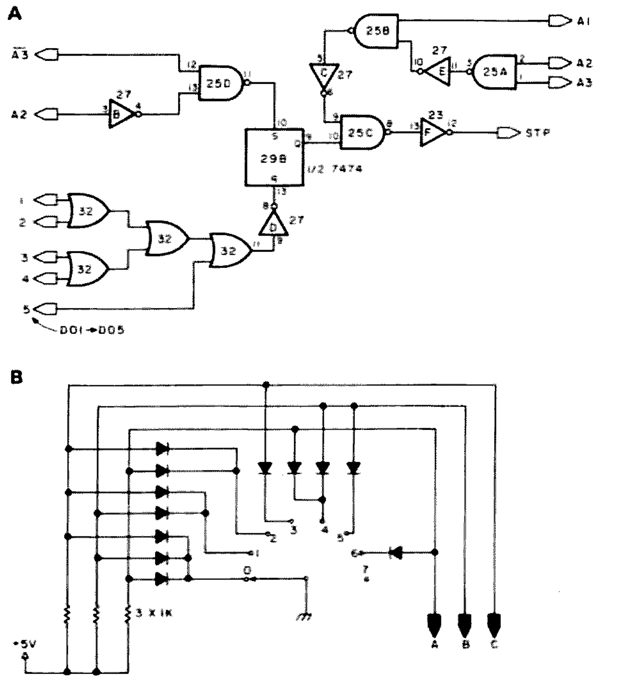

Fig. 3. a) Stop detector; b) Input selector and diode matrix (one of three). Preset controls.

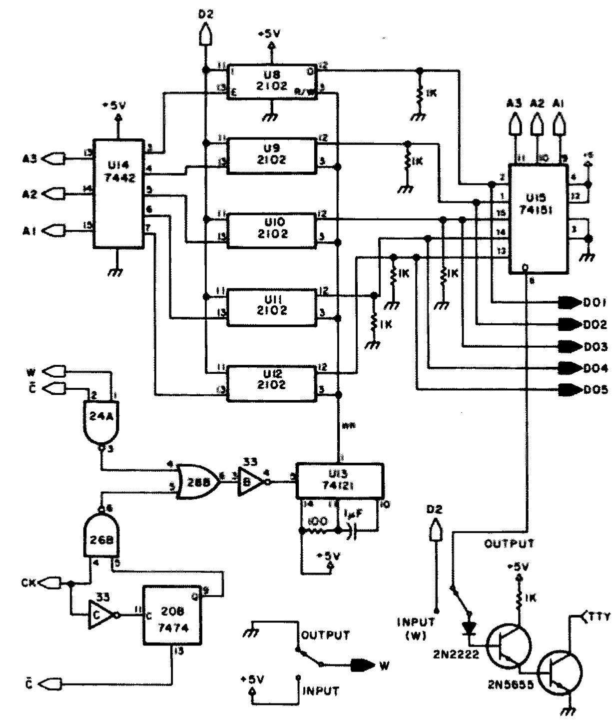

Fig. 4. Memory.

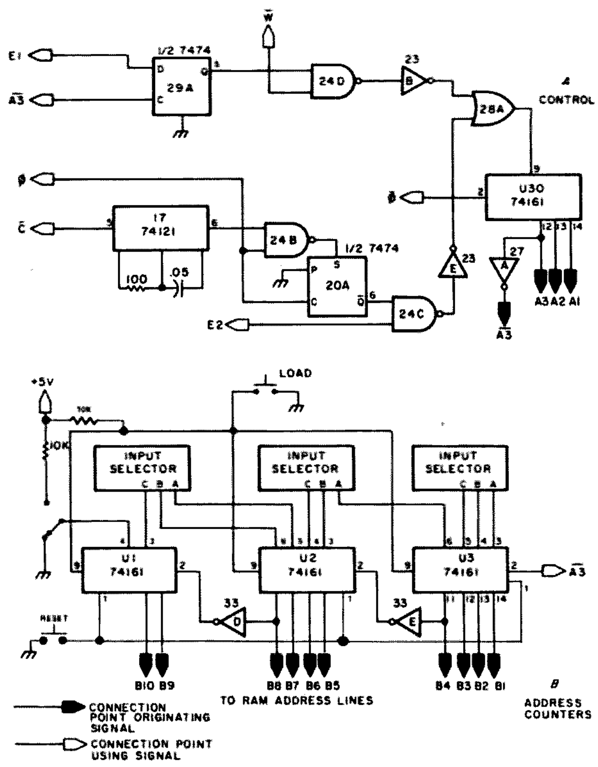

Fig. 5. a) Control. b) Address counters.

function is realized by using D2 to reset flip-flop U19B low. This allows the clock to be applied to the four bit binary counter U4 through gate U26D. After 14 clock pulses, U31B is toggled by the output of the counter through U30A, resetting flip-flop U19B and $\bar{C}$. When the clock then goes high, counter U4 and flip-flop U31B are reset by gate U26C. A duration of 14 clock pulses causes $\bar{C}$ to return high during the stop pulse.

Now, the data bits are being applied to the input of five RAMs. The timing logic must sort out the times when each RAM should individually be enabled and a write pulse applied to write the first data bit into RAM one, the second data bit into RAM two, and so on.

Counter U30 is set up to count the 7 data bits of each letter. See Fig. 5(a). When in output mode, the stop pulse is split into two 22 ms pulses instead of a 31 ms pulse. They are both high, so the end result is to increase the stop pulse at the output of the system to 44 ms. This only slightly decreases the operating speed. Ø is a second clock signal which has twice the period of the clock. As can be seen from the timing diagram, D2 can go low under two possibilities: when Ø is high (lower half of diagram) and when Ø is low (upper half of diagram). If it goes low when Ø is low, it should immediately begin clocking counter U30 with Ø. If it goes low when Ø is high, it should delay counting the first Ø transition and then start counting on the second. This is necessary to ensure that the address 010 lines up in time with data bit one, address 011 lines up with data bit two, and so on. Since a decision is necessary when D2 goes low, C is applied to a monostable U17 to produce a short sampling pulse. Gate U24B uses this pulse to sample Ø. If Ø was low at the time of the pulse, then the output of U24B remains high, and flip-flop U20A remains in a reset state (output pin 6 high). This allows E2 to be applied to the enable pin of U30 through U24C, U23E, and U28A to begin counting. E2 is similar to $\bar{C}$, except it is ANDed with a signal which is only high when the system is in RUN mode and not the STOP mode. Now, if Ø was high during that sampling pulse coming out of monostable U17, a low pulse is applied to the set input of flip-flop U20A through U24B. This sets output pin 6 low, which inhibits enabling of counter U30 until Ø comes along again and toggles the flip-flop back to its original reset state.

Referring to Fig. 4, the three bit output of counter U30 (A1, A2, A3) is applied to the decoder U14. This IC decodes the address and enables the proper RAM.

Now that each RAM is receiving an enable pulse at the proper time at its enable input, sometime during that enable pulse a write pulse must be applied to the read/write input of each RAM. Since no two RAMs are enabled simultaneously, a single write pulse can be applied to all RAMs simultaneously. This signal is developed by the remaining circuitry at the bottom of Fig. 4. W, which is only high when the system should be recording information in RAM, is ANDed with $\bar{C}$, the clock, and a modified version of the clock. The modified clock is produced by flip-flop U20B. This is to produce a write pulse command at every other clock pulse. This combination of signals singles out the times when write pulses are desired plus one extra one. The extra one occurs during the start pulse of the incoming letter and does not do anything because at that time none of the RAMs are enabled (see timing diagram). This command is applied to monostable U13, which produces a negative pulse of the proper duration to write data into the RAM. The output is applied to the read/write terminal of all five RAMs.

The system clock consists of an NE555 timer and one flip-flop, U19A. The .08 μF capacitor charges up through two 97k resistors. When pin 2 sees a voltage of 2/3 Vcc, pin 7 is internally grounded, discharging the capacitor through two 97 Ohm resistors (one different from charging path). When pin 2 gets down

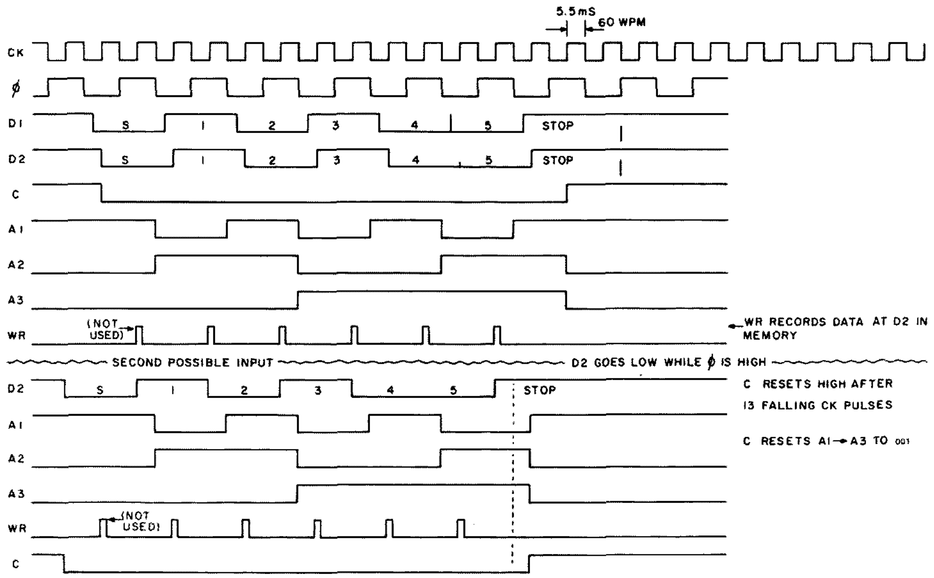

Fig. 6. Timing diagram.

to 1/3 Vcc, the ground at pin 7 is released by the 555, and the capacitor then charges back up to 2/3 Vcc and repeats. This produces a TTL-compatible square wave at pin 3, with the frequency dependent on the capacitor and resistors used (in this design it has a period of 11 milliseconds). Flip-flop U19A divides this clock signal by two to produce ∅.

There are several front panel controls in the unit. The RUN button grounds the set input of flip-flop 31A, which is normally held high by a resistor to Vcc. See Fig. 2(d). This sets output pin 9 high which is enable 1 (E1). E1 ANDed with $\overline{C}$ in U26A and U23C produces E2 mentioned earlier. $\overline{E1}$ is also produced. The flip-flop can be reset by one of two means. A signal (stp) from the stop detector applied to U28C, or the operator depressing the stop button, will cause U23D to lower the reset pin on U31A and lower E1 and E2 immediately. The load pushbutton lowers the voltage on the load input on the 3 memory address counters U1-U3. This causes the memory address (B1-B10) to immediately take on the values of the output to the diode matrix (C1-C10). This is determined by the setting of the address input rotary switches. Finally, the RESET button resets the memory address to all 0s.

If the operator pushes the stop button while the machine is right in the middle of printing a letter, it would be desirable to have the machine stop after it has completed printing of that letter. If the unit stopped in the middle, the Teletype would not print the correct letter. This is taken care of by the upper circuit in Fig. 5(a). E1 goes low when the stop command is received. E1 is applied to the data input of flip-flop U29A. The stop is not transferred to pin 5 until $\overline{A3}$ toggles the flip-flop (A3-low). This happens at the end of each character during the stop pulse. E1 is then ANDed with $\overline{W}$ (used only when printing out data, not when reading data in) and applied to the enable of counter U30 through OR gate U28A. The other circuit applied to U28A has already been described and is used to enable U30 when in the READ mode.

Now we are ready to follow the signal flow from RAM to Teletype machine when the unit is in the OUTPUT mode.

Referring to Fig. 4, when in the OUTPUT mode, the RAM enable selector U14 is receiving a free running count (A1, A2, A3) from U30, enabling each RAM in sequence with three counts between RAM five and RAM one, when none are enabled. These three counts last 22 ms each and are used to insert the start (one count) and stop (two counts) at the output. The data outputs from the five RAMs go to the inputs of an eight-bit data multiplexer U15. U30's count is also applied to U15's selector input. A3, A2, and A1 determine which of the eight inputs is applied to the single output. Since U30 supplies a free running count, U15 "scans" its eight inputs. It is set up so that when U14 enables RAM one, U15 transfers RAM one's data output to its output. During the start pulse, the input to U15 is grounded, and, during the two counts of the stop pulse, the two corresponding inputs to U15 are tied to Vcc. So U15 is a parallel to serial converter for the five data bits from RAM and also inserts the start and stop bits necessary to operate the Teletype machine.

As seen in Fig. 1, the outputs of the RAMs are also tied to the stop detector. This circuit detects when any character has all five bits low when coming out of memory (BLANK key), and, if so, sends a signal (stp) to control the stop.

As seen in Fig. 3(a), U32 is connected to the RAM's outputs (D01-D05), so that pin 11 goes high unless all inputs are low. So, if the character being sent is anything other than a blank, at least one data bit will be high. When a data bit goes high, U32 pin 11 goes high, U27 pin 8 goes low, which resets the output (pin 9) of flip-flop U29B low. U25B, U25A, U27E, U27C decode the condition when A3, A2, and A1 are all high at the same time. This is during the first half of the stop pulse. So, when the stop pulse comes along, U25C samples the condition of flip-flop U29B. If it has been reset (any character except blank), the stp signal remains unchanged (low). If, however, the flip-flop had not been reset during the data bits (BLANK key), U25C will sample the flip-flop and see it is high, and stp will go high, stopping the system. Flip-flop U29B is then set during each space count by $\overline{A3}$, A2, and U25D to have it ready for the next character.

The serial output signal from U15 is then applied to the output driver. A TTL signal must be used to open and close the selector magnets of the Teletype machine. They require about 60 mA of current. The output transistor must be able to handle a collector current of 60 mA, and the CE voltage must be able to handle 150 volts when not conducting. A 2N5655 was chosen for the output transistor. It is rated at 300 volts and over 100 mA. The TTL signal is applied (Fig. 4) through three diodes to ground. Thus 2.1 volts are required to turn on the driver transistor. 2.1 volts is a reasonable switching voltage for TTL logic. The remainder of the TTY loop can be seen in Fig. 7. The TU (terminal unit) converts the audio FSK signal from the receiver into a dc signal to switch the selector magnets. To receive, the generator can be in any mode except outputting. The reed relay senses

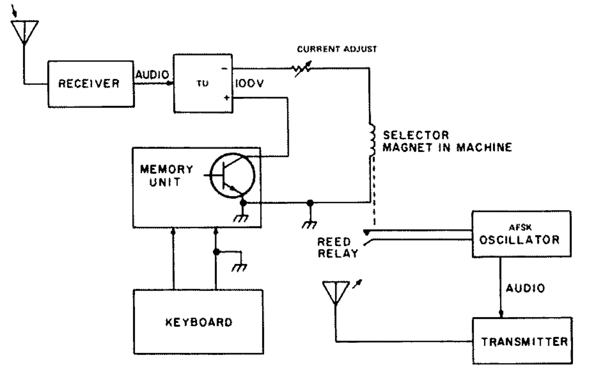

Fig. 7. This shows how the unit is connected in an amateur RTTY station.

changes in TTY loop current from memory or keyboard and drives an AFSK (audio frequency shift keyer) oscillator, which is fed into the transmitter.

The RTTY station can do any of the following functions:

1. Put received message in memory and print.
2. Put message from keyboard into memory and print.
3. Transmit from keyboard and print.
4. Transmit from memory and print.
5. Send received message to printer only.

If it is desired to transmit at 100 wpm, the .03 uF capacitor in the clock circuit is switched out, leaving .05 uF. The speed of the generator must match the running speed of the machine, but you can type into memory as slowly as you want.

I recommend breadboarding of some type over PC boards because of the wiring complexity.

I have not included a power supply diagram because many have appeared in previous articles. Plus 5 V dc regulated is required, and an LM309 on a heat sink will do the job well. The output consists of an NPN transistor with emitter to ground, so it can be inserted directly into a 60 mA TTY loop. Also, provision is made for local copy on the printer (or video display) of data as it is typed into memory.

Good luck, and I would appreciate any comments from builders. ■

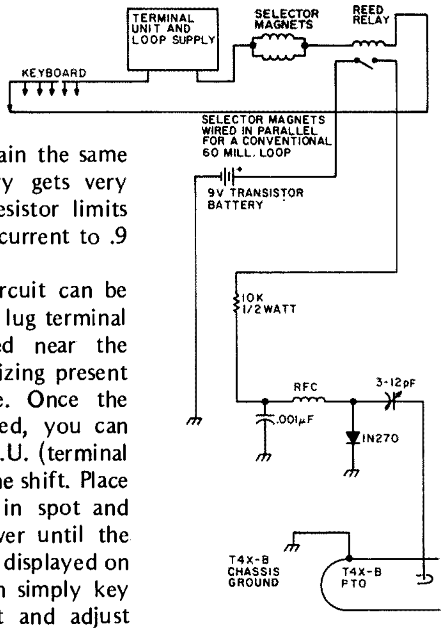
FSK for the Drake -- easy



This circuit is actually a saturated diode keyer right out of the handbook, but instead of using an FSK driver to supply the forward bias needed for the diode, I used a 9 volt transistor battery, which is supplying .9 milliampere to the diode. Since the diode is non-linear, the current does not change in proportion to the voltage across it. At that low current, the battery will last a very long time, and even when it does start to get weak, the current will remain the same until the battery gets very low. The 10k resistor limits the total circuit current to .9 mil.

The whole circuit can be mounted on a 3 lug terminal strip and placed near the T-4XB PTO utilizing present chassis hardware. Once the circuit is installed, you can use your own T.U. (terminal unit) to adjust the shift. Place the transmitter in spot and tune your receiver until the space is properly displayed on your scope, then simply key the shift circuit and adjust the 3-12 pF variable to obtain the proper shift by watching the mark display on your scope.

The reed is shown open, indicating no loop current. When the loop is on, the reed contacts are closed, completing the shift circuit. In this condition, with the keyboard closed, the vfo is downshifted 850 Hz to indicate a mark; when the keyboard is open, the vfo upshifts to indicate a space. To reverse, just wire the reed so its contacts are open when the loop is on. ■

Baudot to ASCII Converter

-- use it for OSCAR RTTY

Among the current crop of Teletype machines that are being retired from commercial service, there are quite a few ASCII machines, such as Models 33 and 35. If you are just getting into RTTY, or you are looking for more equipment, there are a number of reasons to consider building your station around an ASCII machine. First of all, the newest and most modern machines are the ASCII machines. Indications are that ASCII will be allowed on the air sometime in the near future; in fact, it is legal in Canada right now. The keyboard is very similar to a standard typewriter, which is an advantage if you already know how to type. It is also a good place to start if you don't. Finally, if you eventually get interested in microprocessers, you can use the TTY machine as your terminal.

In order to communicate in Baudot code on the amateur bands, you will need a code converter which converts Baudot to ASCII, when you are receiving, and ASCII to Baudot, when you transmit. This article describes a two-way code converter, built on a single PC board, which will allow you to receive and transmit at all amateur and commercial speeds. A number of these units have been built by amateurs in the Winnipeg area and are in use on the HF and VHF bands. During the design and construction of the converter, I learned about some aspects of digital logic design that do not seem to be very widely known by amateurs. I hope that I can pass some of this information to the reader. Most of the discussion of the operation of the converter will be in terms of logical functions, rather than in terms of currents and voltages, because this is the way I visualize things.

Principles of Code Conversion

The ASCII code is comprised of seven information bits, so there are 128 distinct combinations, or ASCII characters. An eighth bit, the parity bit, is also transmitted, but is generally ignored at the receiving end. The eight bits are framed by start and stop bits during transmission and reception.

The Baudot code has only five information bits, so there are only 32 possible combinations. In order to accommodate all the required letters, numbers, and punctuation marks, two of the Baudot characters are used to select alternate character sets in the printer. These are called the LTRS and FIGS shift characters. Thus the interpretation of Baudot code depends upon which shift character was previously transmitted. The five bits of Baudot are also framed with start and stop bits for transmission.

There is no simple relationship between the bit pattern of a Baudot character and the pattern of the corresponding character in ASCII. This means that there is no way to use a few logic gates to translate Baudot to ASCII. What is required is a translation table. If such a table is coded into a read only memory, all you have to do is to present the five Baudot bits as the address input to the ROM, and the seven ASCII bits for the corresponding character will appear at the data outputs. (See Fig. 1.) Because there are two possible interpretations of the Baudot character, a flip-flop is used to remember the shift status, and the output of the flip-flop is used as a sixth address bit. When this bit is high, figures are generated, and, when it is low, letters are

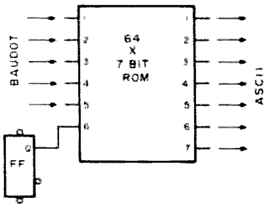

Fig. 1. Baudot to ASCII conversion.

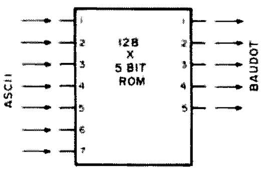

Fig. 2. ASCII to Baudot conversion.

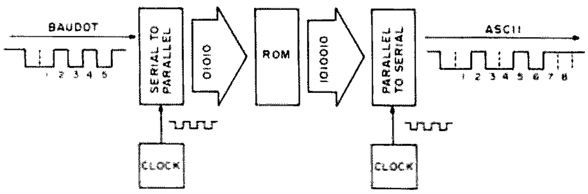

Fig. 3. Conversion of serial TTY data.

generated. The complete conversion table requires 64 seven-bit words in the memory.

Conversion from ASCII to Baudot can be done with a ROM having seven address inputs and five data outputs. (See Fig. 2.) It is also possible to use a smaller ROM and do some of the conversion with external logic, but this approach generally results in a more complex circuit. Again, a flip-flop is used to remember the current shift status. ASCII to Baudot conversion is complicated by the requirement that the FIGS or LTRS characters must be inserted into the data stream, so that the receiving station interprets the data correctly. Whenever the incoming ASCII changes from letters to figures, a FIGS character must be generated, and when the ASCII returns to letters, a LTRS character must be generated.

So far I have been discussing the conversion of parallel data from one code to another. This can be done within a few microseconds, because all the incoming data bits are present simultaneously. However, RTTY signals are transmitted in serial form with start and stop pulses. This means that a serial to parallel conversion must precede the code conversion, and a parallel to serial conversion must follow it. Fig. 3 shows the letter R in Baudot code being converted to serial ASCII. The serial input is controlled by a clock running at a fixed frequency determined by the baud rate of the incoming signal. For example, Baudot code having a maximum speed of 60 wpm has a baud rate of 45.45. Likewise, the serial output is controlled by another fixed frequency clock. In the case of ASCII with a maximum speed of 100 wpm, the baud rate is 110. Thus, a speed conversion is obtained, as well as the code conversion. In the case illustrated, if the Baudot is arriving at maximum speed, the ASCII will be leaving the output side at about half its maximum speed. There will be pauses between the characters, and, during the pauses, the output line will remain in a marking state. This is a result of the upward conversion of speed.

When a downward speed conversion is required (for example, when converting from 100 wpm ASCII to 60 wpm Baudot), the average speed of the incoming data must be restricted to 60 wpm. Otherwise a condition known as overrun will occur, and some characters will be lost. This is no problem when I am typing on my 33ASR because I can only type at 10 wpm or so. However, in the situation when a steady stream of data is arriving at 100 wpm, there is no way on earth to convert it and make it print on a 60 wpm machine. You might think that a memory that would store the excess characters would solve the problem, but eventually the memory would fill up, and the overrun would still occur. The only solution is to limit the speed of the incoming data to a level that the converter can handle.

Circuit Description

The translation tables for both conversions are contained in a single 1702 PROM. This device has a capacity of 256 eight-bit words, giving me lots of space to play with. There are eight address inputs and eight data outputs. The way I have partitioned the memory may be seen in Table 1. The desired portion of the memory is selected by the high-order address bits.

For example, when bit 8 is high, the table to convert Baudot to ASCII is selected. The five low-order address bits are the incoming character to be translated. Bits 6 and 7 are used to select portions of the table that convert Baudot letters or figures, as well as a special portion that is designed to provide automatic unshift on space. When address bit 8 is low, the ASCII to Baudot conversion is selected. The seven low-order address bits are the incoming ASCII character. Bits 6 and 7 are changed from data to control information by a 74153 multiplexer, which behaves like a two-pole 4-position switch.

The data contained in the storage locations of the memory consists of a character in the low-order bits and control flags in the high-order bits. In this manner, it is never necessary to decode a character to determine what to do with it. For the Baudot to ASCII conversion, seven data bits are occupied by the ASCII character. Bit 8 contains the current shift status. For the ASCII to Baudot conversion, more control flags are required, but, fortunately, the Baudot character only occupies five bits. Bit 6 is the Baudot shift required for that character. Bit 7 is a flag that, when on, says to inhibit insertion of the shift character. It is used for characters that may be transmitted in any shift. Bit 8 is another flag which causes the entire character to be ignored. It is used for ASCII codes that have no Baudot equivalent.

The insertion of LTRS and FIGS characters in a stream of Baudot is done by a five-bit multiplexer, which is constructed of a 74157 and a pair of NAND gates. A single control line is used to switch from the output of the PROM to the shift character, which is hard-wired except for the middle bit. This bit is obtained from the shift status kept in the 74109 flip-flop. The decision to insert a shift character is produced by a 7410 triple NAND gate, which is connected in an exclusive OR configuration. This device compares the shift status in the flip-flop to the shift information coming from data bit 6 of the PROM.

The serial to parallel and parallel to serial conversions are performed by a pair of AY5-1013 UARTs. Each UART contains a serial receiver and a serial transmitter. The two sections are independent, except for some control information which defines the structure of the serial data. Besides the data inputs and outputs, each section has status lines that are used for communication between the UART and the control circuits. When the UART receiver has a character ready, it sets the DAV (data available) line high. The external circuit should process the character and then indicate that it is no longer needed by strobing the RDAV (reset data available) line. The transmitter section has a TBMT (transmitter buffer empty) line, which goes high when the buffer is empty. The external circuit should wait until TBMT is high and then may load a character into the transmitter by strobing the DS (data strobe) line.

The portions of the circuit I have described so far are all concerned with operations on five- or seven-bit parallel characters. The PROM, multiplexers, and UARTs run under the control of three other portions of the circuit, which I am about to describe. First, there is the ASCII sequence generator, which consists of one flip-flop and two NAND gates. When the DAV from the Baudot UART goes high, the sequencer waits for 1/2 a clock and then puts out a negative pulse for 1/2 a clock. This pulse loads a character into the ASCII UART, clears the data available flag in the Baudot UART, and loads the shift flip-flop.

The Baudot sequence generator consists of a 74161 binary counter, a 7442 decoder, a 7454 AND-OR-INVERT gate and a few NAND gates and inverters. The sequence is initiated when the DAV from the ASCII UART goes high. Table 2 shows the steps that the circuit goes through. The output signals are negative pulses that are used to load characters into the Baudot UART, load the shift flip-flop, and clear the data available flag in the ASCII UART. The 74161 is connected as a 3-bit counter, so it has eight states. Its output is decoded by the 7442. The two count enable inputs of the counter are used to hold the counter in a given state when necessary. The AOI gate controls parallel loading of data into the counter, permitting jumps to

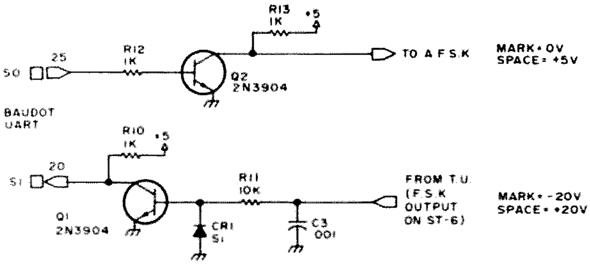

Fig. 6. Baudot interface.

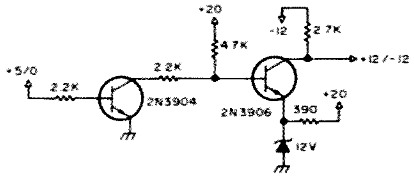

Fig. 7. Driver for FSK diode.

new states.

Finally, there is the mode switching circuit, consisting of one JK flip-flop and a couple of NAND gates. When the flip-flop is in the high state, the Baudot to ASCII conversion is selected by enabling the Baudot UART, addressing the upper half of the PROM, and gating the DAV line to the ASCII sequencer. In a similar manner, the ASCII to Baudot conversion is selected when the flip-flop is in the low state. Input to the mode switching circuit comes from the DAV lines of the two UARTs. With no inputs, the flip-flop toggles. When an input signal appears, the flip-flop holds in the required state until the conversion is completed and the DAV is cleared. It then switches to the other state if the DAV from the other UART has come on, or it just toggles if there is no input. Note that there is plenty of time to interlace the conversions this way because the control circuits are clocked at 16 times the baud rate.

The clock generator consists of a master oscillator and two divider chains. The 555 is connected as a free-running oscillator at .105.6 kHz. This frequency is divided by 60 to produce the ASCII clock. The Baudot divider chain consists of three 74161 binary counters connected as programmable dividers. The first two divide by 29 or 44, and the third divides by 2, 3, 4 or 5 to produce the Baudot clocks for the four speeds ranging from 60 to 100 words per minute. All clock outputs are accurate to better than 0.2%, once the master clock is set. It would be possible to economize there by using separate 555 oscillators for ASCII and for Baudot, particularly if only one Baudot speed were desired.

Design Criteria

In designing the code converter, I generally followed the recommendations of the Fairchild TTL handbook.[1] You will notice that there are no monostable multivibrators or RC coupling elements in the circuit. This allows me to retain the inherent noise immunity of TTL logic. Also, I have used synchronous edge-triggered flip-flops and counters in the control circuitry. These devices are only sensitive to input conditions during the low to high transition of the clock. The use of synchronous logic makes the design very predictable and free of glitches and unexpected states. I also paid attention to the fan-out rating of the devices. Most TTL-compatible MOS devices such as the UARTs and the PROM are able to drive only one standard TTL load. Where more drive was required, I used gates or inverters as buffers. Another solution would be to drive only low-power Schottky TTL from the MOS. In this case, up to four LSTTL inputs could be driven.

Interfacing

The logic levels at the serial input and output lines of the two UARTs are TTL-compatible – that is, Mark = 1 = +5 V and Space = 0 = 0 V. These lines may be connected directly to any other TTL logic, but, usually, some interfacing is required for equipment such as a terminal unit or a TTY machine. Considering the ASCII end first, the most common requirement would be connection to a 20 mA current loop. If you are lucky enough to have a Model 33 or 35 Teletype that was formerly used for TWX service (there will be a telephone dial on the right-hand side), the circuit of Fig. 5 is for you. You will find two 50-pin micro ribbon connectors, dangling underneath the machine, that formerly connected to the modem (Bell 101C Dataset). No

Table 2. Steps of the ASCII to Baudot sequence.

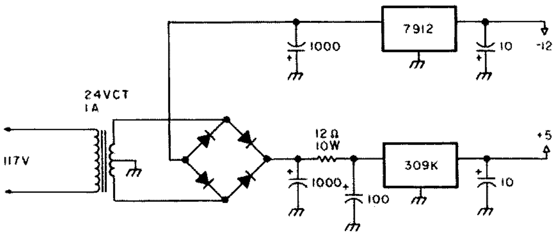

Fig. 8. Power supply.

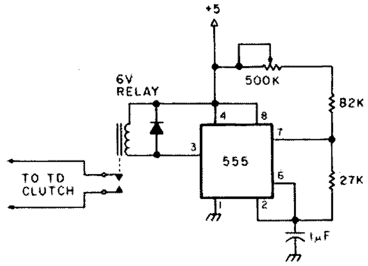

Fig. 9. Tape reader control.

modifications to the machine are required. Just obtain a mating female connector, wire it to the interface and plug it in. You will also require a source of plus and minus 20 volts at 30 mA or so. A Model 33 does not use the +20, so this may be omitted. The connections to pins 1 and 2 are the printer loop, and the connections to pins 7 and 8 are the keyboard loop. If you have a Model 33 without all the telephone stuff, just forget about the connector and wire these lines directly to the machine.

At the Baudot end of the converter, the usual requirements will be connections to a terminal unit (demodulator) and to an AFSK oscillator (modulator). Interfaces for the popular ST-6 and AK-1 are shown in Fig. 6. The ST-6 interface is very tolerant of input levels and may be used with many other sources of Baudot. The AK-1 interface may be modified to an open collector stage or to a higher voltage stage for use with other modulators. If you need both positive and negative levels to drive an FSK diode, use the interface shown in Fig. 7.

Power Supply

The code converter requires a regulated +5.0 volt supply at about 600 mA and a regulated -12 volt supply at about 50 mA. In addition, voltages of -20 and +20 at about 30 mA may be required for the interfaces. Regulation is not necessary here. One design of a suitable power supply is given in Fig. 8. Many other designs would work equally well.

Tape Controller

When I run a tape on my ASR Teletype, I get overruns in the code converter resulting in missing characters in the 60 wpm Baudot output. A simple solution to this problem is shown in Fig. 9. The 555 is connected as a free-running oscillator, with the frequency adjustable from 2 to 10 Hz. The relay

Parts List

C1	10 uF, 25 V electrolytic capacitor
C2	680 pF mica
C3	.001, 50 V ceramic disc
CX1-CX11	.05-.1, 25 V disc ceramic despiking capacitors
CR1	1N914 or similar silicon diode
Q1, Q2,	2N3904 or similar NPN transistor
Q3, Q4	2N3906 or similar PNP transistor
R1	100 Ohm ½ Watt resistor
R2, 6, 7, 9, 21, 22	2.7k Ohm ½ W (1.5-6.8k Ohm acceptable) pullup resistors
R3	4.7k Ohm ½ W
R4	5.6k Ohm ½ W
R5	2.5k Ohm potentiometer, printed circuit style (multi-turn preferred) Master Clock Adj.
R10, 12, 13, 17	1k Ohm ½ W
R11, 15	10k Ohm ½ W
R14	330 Ohm ½ W
R16	3.3k Ohm ½ W

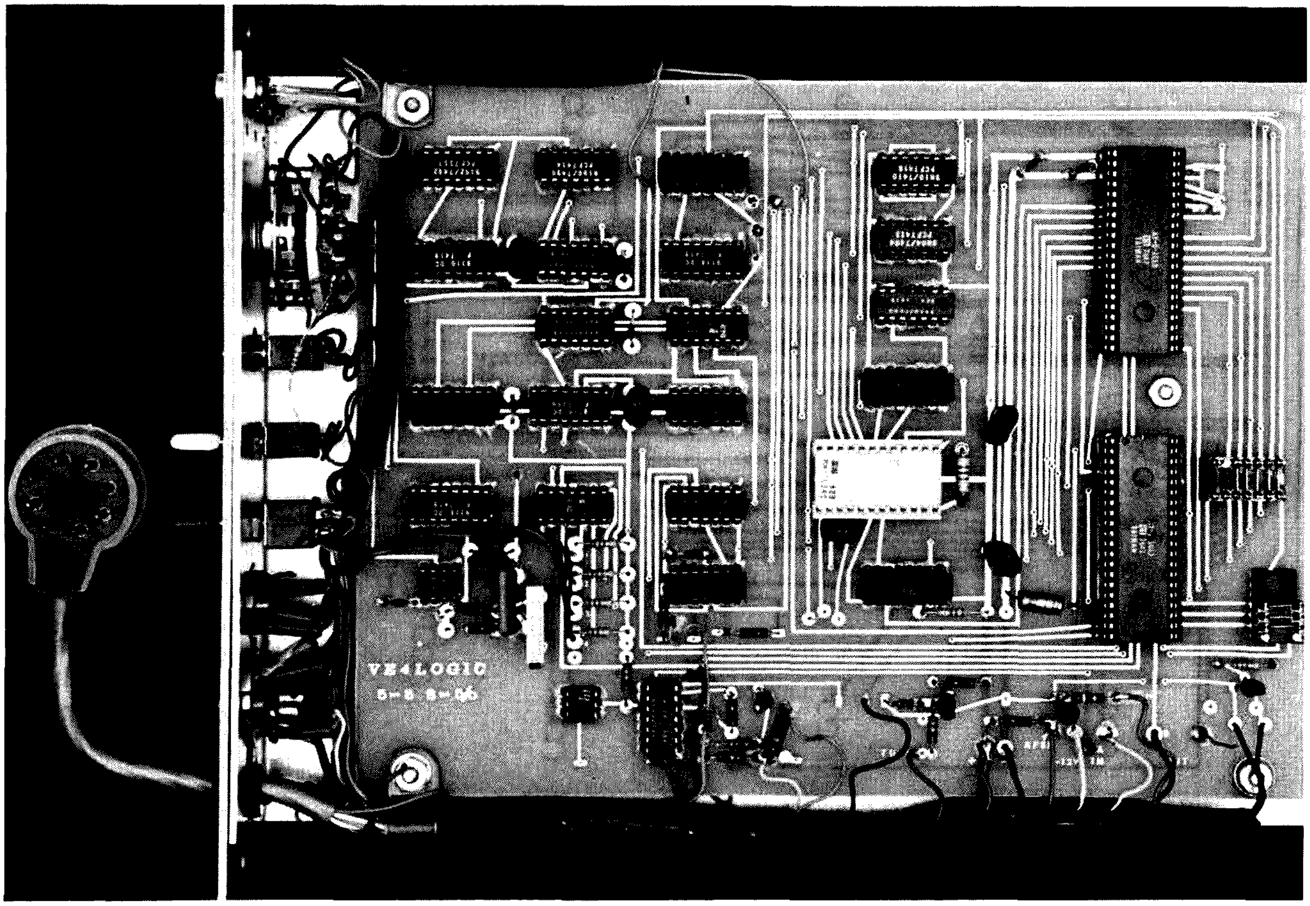
A semi-kit, consisting of a double-sided PC board with plated-through holes, a 1702 EPROM programmed and tested, sockets for U10, U11, U13 and complete assembly instructions, is available at a cost of $62.50 from: VE4 LOGIC, 76 St. Clair Blvd., Winnipeg, Manitoba, Canada R2C 0V2.



contacts close once during each oscillator cycle, causing the tape reader (TD) to transmit one character. With this circuit, you can adjust the speed of the tape to a speed that the converter can accept, and everything runs just fine with no missing characters. You can cut a tape from a received Baudot signal and transmit it later, or make a tape locally from the ASCII keyboard and transmit it in Baudot code.

One-way Conversion

The first code converter I built is shown in Fig. 10. It has two UARTs, the same PROM, one 7404 and one 7474. I used separate 555 clocks running at 727 Hz and 1760 Hz. If you want to make a gradual start into code conversion, or if you just want to listen in on amateur and commercial activity, then this circuit is ideal. If you later decide you want to transmit as well, the circuit could easily be expanded to the two-way version.

Construction

I assembled the prototype of the code converter on an IC breadboard and had no particular problems. Everything worked just the way the circuit logic and manufacturer's data sheets predicted it would, the moment I plugged it into the breadboard. A group of local amateurs, VE4BF, VE4CM, VE4XD and VE4YD, was formed to design and produce PC boards for the converter. Because of the circuit complexity, we decided upon a double-sided board with plated-through holes. Several copies have now been built using this board.[2]

If you build the circuit (or part of it) yourself, using your own board or hand-wiring or wrapping, there is nothing critical about the layout. Just follow normal TTL construction practices, keep the interconnections shorter than 18 inches, and bypass the supply buses occasionally. The only adjustment required is the clock trimmer. This can be set with a counter if it is available. If not, do it on received signals by determining the range over which error-free copy is obtained and then setting the trimmer to the midpoint of the range. I can give very few suggestions on troubleshooting, other than to try to localize the trouble to a small portion of the circuit. If you use only first quality ICs, the circuit should work the first time you try it, and no debugging will be required. ■

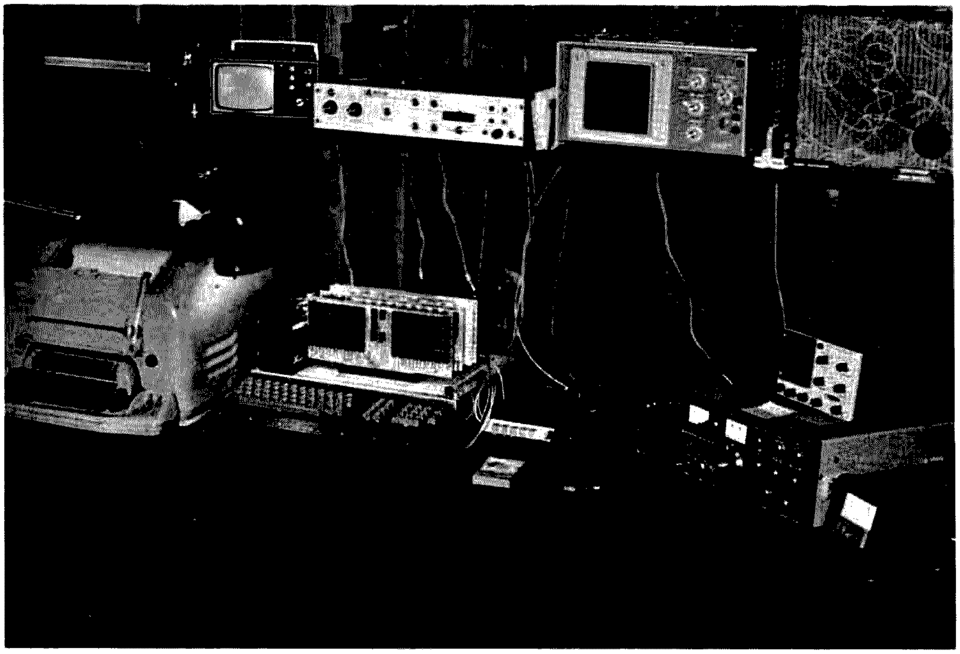
Digital Group RTTY Micro

-- a natural team

Because I was interested in electronics, including amateur radio, I decided to get in on this new thing called microprocessing. I have worked with digital electronics before and have put together some successful hardware projects. I quickly found that there were a few small computer systems available, so some wise decision-making was necessary.

I sent away for literature and paid close attention to magazine advertising. Then, things were pretty well summed up for me at the Spring, 1976, Rochester, N.Y. Hamfest, where they had a computer seminar. Pior to that I seemed to have a choice between MITS, IMSAI, and HAL. But now there was a new one on the scene – the Digital Group. I was planning to get the HAL 8080, but, when I found out that the Digital Group System could actually do something, and that software was only $5 per cassette, I was *sold*. Further discussion with the fellows at the seminar confirmed that the Digital Group was for me. I knew nothing about software or programming, so the best bet had to be a company that would get me started without overcharging.



The author's shack, showing his Digital Group 8080A-4BD system with 10K RAM memory, 4 input/out ports x 8 bits, and 16 line x 32 letter character generator; surplus keyboard; Kleinschmidt 60 wpm Baudot machine; Ampex Micro 9A cassette recorder; Icom IC-22; and Kenwood TS-520.

I took delivery of my system on the July 4th weekend of 1976. I managed to complete the unit inside 3 days – it didn't work. After searching under a magnifying glass and bright light, I found and removed the solder bridge that could have done me in. Sure enough, there it was, telling me via my TV monitor to "Read 8080 Initialize Cassette." I was off in another world, making it play the Star Spangled Banner while printing the flag on the TV. It would also play a number guessing game, send Morse code from the keyboard, and receive RTTY on the TV.

Since I had also ordered an additional 8K of memory with the system, I quickly began construction of the extra memory board. This board, along with the 2K of memory on the processor board, is what makes it a 10K system. Well, this time things didn't go so well. Nothing really seemed to work, including the Tiny BASIC tape and the Ham-1 tape. After some phone conversation with Digital Group and a check of my tapes by the software people (Dianne Howerton is very patient and

understanding), I finally paid attention to the construction instructions. Back *again* to the bright light and the magnifying glass. Sure enough, just as written in the instructions. I had forgotten to solder two socket pins. Two in over a thousand isn't bad, is it? Anyway, the BASIC worked, and the Ham-1 tape worked.

Being inquisitive, I began to "dump storage" and look at what was going on in there. After reading and more reading, I finally was able to start some programs of my own. First I ran a few simple things, and then I began block moving data, studying subroutines, and learning how to change memory addresses. Little by little I worked on making modifications. Before long I was surprised at how many octal instructions I could remember — load, jump, call, return, compare and jump based on flag sets, and so on, throughout the Intel 8080 program card. I found that I could remember octal more easily than hex, and, since the Digital Group 8080 operating system was in octal, I adopted it.

I found that the Digital Group Ham-1 RTTY transmit was not really doing as much as I wanted it to do, and, in fact, the Digital Group instructions encourage making modifications and improvements. One of the more aggravating problems was missing letters when typing too fast, especially during automatic figures-letters shifting, and another problem was no carriage return or line feed. The reed

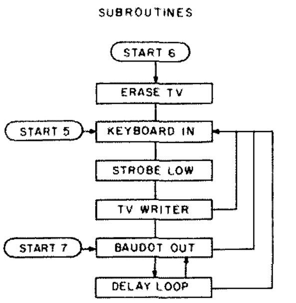


Fig. 1.

switch ASCII keyboard would barrel right along when 60 wpm was the limit. Of course, a mechanical machine like my Klienschmidt would mechanically prevent typing too fast. For a while I was using Tiny BASIC Baudot for amateur RTTY, but it kept giving out automatic error messages. It was for BASIC, not ham use.

At any rate, I wanted to have a RTTY transmit program which would have automatic carriage return after 70 letters, and, after accomplishing that, I went further to add an additional carriage return after 64 letters and a space. I then made a program to act just like punching paper tape, where letters entered at the keyboard were shuffled off to a blank memory area and stored. Executing the read program would then go back to the start and read the memory whenever called and as many times as I wanted.

Next, I put in a program modification to back step (decrement) the pointer, and back spacing for error correction was born. I even made a quick little program to send K2AOU in Morse code on the output and "Here is K2AOU" in RTTY — all at the punch of a number at the keyboard. I have future plans for it to turn the transmitter on and off. You had better not let it control your frequency, though; I heard of one fellow working WWV that way!

My ultimate goal was to build a buffer system. I had a discussion with an associate who had done some FORTRAN and general programming, and I learned about rotary pointers and fullness registers. I also dismantled the CW transmit part of the Ham-1, which works great as is but is scattered throughout memory. From it I learned more about pointers and timing loops, and I cleaned up the CW program's structuring within memory. Mind you, I did all this *before* Digital Group came out with their Dissassembler.

I felt that the operator with only 2K of memory needed a fair deal, so I began work on a 2K FIFO (first in first out) buffer, as outlined here. It is a program which can be useful to any RTTY enthusiast, essentially a sidekick to the amateur RTTY station. Actually it takes only 500 bytes of instruction space and 256 bytes of scratchpad memory. The machine language is for the Intel 8080A. Those of you who have 8080 systems from other manufacturers can probably adapt the program. Be careful to observe Digital Group subroutines for TV output, delay loops, and keyboard input. If you have more memory, of course, you can add RTTY receive, additional buffers, CW ID, here is key, etc.

The Digital Group Operating System is based on the following routines:

1. READ in a new program from audio cassette to memory.
2. WRITE out a program from memory to the audio cassette record input.
3. OCTAL STORAGE DUMP of sequential memory locations.
4. KEYBOARD PROGRAM memory by entering each byte in octal numbers.

5.6.7.8.9.0. User assigned "go to" or "execute" at specified addresses.

How It Works

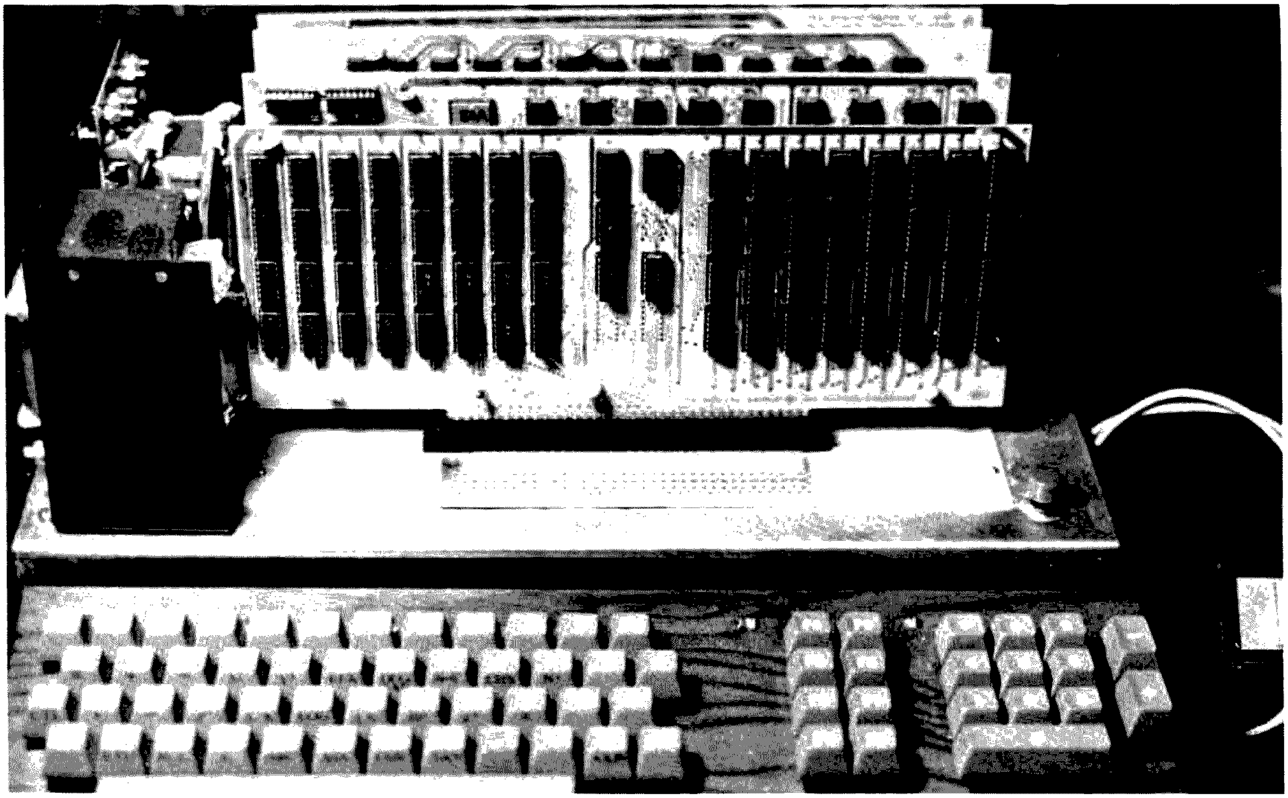
It takes time to output Baudot RTTY, time for the start pulse, time for the five bits and time for the stop pulse. During this time the computer is kept busy, continuously sampling the keyboard input for action. If a key is pressed, it holds the letter, waits for the keyboard strobe to go low again (one letter per keystroke please), and then sweeps the letter off to the proper storage point in the buffer. Write storage point, read storage point, and storage fullness are all kept track of by special pointer bytes, including the location of the last carriage return, whether manual or automatic. This software is set up for 60 wpm output. If you wish to experiment with other speeds, there are three memory locations to work with — 007 304 is 015 for 60 wpm, 010 for 100 wpm. 007 154 is 064 for bit length, and 007 172 is 112 for the stop pulse. This can also be worked on if you have other than a 2 MHz clock speed.

Output Connections

The system output for the

Memory Blocks:	
000 000 TO 000 377	Digital Group PROM
001 000 TO 001 277	Digital Group Operation System
001 300 TO 001 316	Start #5 Buffer Preload
001 317 TO 005 055	Digital Group Operating System
005 056 TO 005 075	Part of Buffer Preload
005 076 TO 005 123	Operating System
005 124 TO 005 136	Part of Buffer Preload
005 140 TO 005 247	Keyboard Subroutine
005 250 TO 005 274	Delay Loop Subroutine
005 277 TO 005 377	Operation Monitor Title Page
006 000 TO 006 377	Buffer Scratchpad (initialize full of 240s)
007 000 TO 007 277	Baudot Output Subroutine
007 300 TO 007 362	Start #6 Buffer load and read
007 363 TO 007 377	Start #7 Buffer Read Only

Table 1. ASCII to Baudot buffer system (FIFO). As you can see, no space is wasted to put this in 2K of memory. For more simplicity, one could eliminate the buffer preload and the buffer read only routines, but these are quite handy. An address is specified by page number and byte number, i.e., 007 000 in octal. When giving the address to the computer, always give it low first and then the high.
303
100 Means jump to page 7, byte 100.
007



serial Baudot is port 002 lsb. I connect from this output through a 1000 Ohm safety resistor to a HAL ST-6 terminal unit. Inside the HAL there is an extra switch position for the optional 425 Hz discriminator. You can add a connector on the cabinet or make use of an extra pin on the back. Position 1 is then 850 shift, position 2 is computer output and position 3 is 170 shift. Because I wanted to be able to output either shift, I removed the AK-1 from this switch and installed a separate one. I also placed a jumper from the autostart bus to an open section of the input switch to turn on the page printer when in the computer position. Other connections to the RTTY loop can be made, but, by all means, use caution! TTL and loop voltages do not survive together. Refer to the article "How to Use Those Old Teletypes," *73*, February, 1977, p. 88. Simpler yet would be to output to port 001, the built-in RTTY oscillator.

Instructions For Use

After reading in your tape to the operations monitor, hit number 6 to use the buffer in real time. The processor will go to 007 300 and loop and wait for your message. You will have to be a good typist to get into the buffer to any depth, but it is very handy during figures to letters shifts and carriage return line feeds. When you hit the keys too fast for the output speed, the buffer remembers everything and puts it out in order. It does automatic carriage returns at the end of 70 letters or after 64 letters at the next space. Figures-letters are automatic in the ASCII conversion, and, whenever you hit a carriage return, it is automatically carriage return, line feed, letters. Hitting a control alpha will exit back to the operations monitor. ASCII % is Baudot bell, and ASCII # is Baudot H (STOP). Hitting a 5 from the operations monitor will cause the processor to go to 001 300, loop, and wait for you to preload the buffer with your next message of up to 250 letters, while the other station is sending to you on your page printer. When it is time to transmit back, hit control L and continue to type into the buffer. The processor will output your message in Baudot while you continue to feed into it with ASCII. If you are slow, it will soon catch up to you. The whole idea here is that you get a 250 letter head start, just as if you were using punched tape. Also, during the preload mode, if a mistake is made, just key in an ASCII delete and the buffer will step back one space at a time. Hitting a 7 from the operations monitor will execute at 007 363 and read the buffer contents from the start at any time.

What Kind of Hardware?

If you only want this one item of software, you could get a single board system going with an 8085, 1K PROM, and 256 bytes of RAM. The board could be mounted underneath your ASCII keyboard and remain dedicated to this one job. If you are the innovative and inquisitive type (and bore easily), then you will want a more flexible system. I am quite pleased with the Digital Group System, as it offers a lot of flexibility. CPU boards can be changed at any time, drawing from 8080A, Z-80, 6800 6502, and others, as they become available. The system comes with 2K of RAM memory on the CPU board 4 parallel input output ports, a TV character generator, and 1100 baud cassette interface. I'm using port 000 in for the ASCII keyboard. Port 000 out drives the TV generator's 512 byte memory, port 001 lsb in and out is for the cassette tape system, and port 002 lsb out is the Baudot serial RTTY output. My total memory at this time is 18K.

Locally, I am working on the air with Bob Hanson WB2DHL, and Ed McNeely K2RQB. We are trying to convince WA2BTG to join us, but, we've had no luck yet. We monitor two meter FM on 147.15 MHz RTTY and carry on at times on 146.25-85 (Oswego Repeater). Shhhh... we've even sent programming at 1100 baud on the air with super results. Hurry up with ASCII, FCC! ■

KEY BOARD IN SUBROUTINE

005 140	333 000	Input Keyboard	
005 142	247	Set Flag	(Key Pressed?)
005 143	360	Return +	(Key not Pressed)

005 071	065	M= M-1	(Write Pointer)
005 072	065	M= M-1	
005 073	303 124 005	Jump	

NOTICE:

BUFFER READ ONLY (OPTIONAL)

Address	Code	Step	Comment
		Start #7	
007 363	076 377	A= 377	(Fill fullness pointer)
007 365	041 133 007	Load H&L	
007 370	167	Store A	
007 371	257	Clear A	
007 372	056 136	L= 136	
007 374	167	Store A	(Set read pointer to 0)
007 375	303 322 007	Jump	(Jump into Buffer)

Using Start #5, preload with RYRY, The Quick Brown Fox, CQ DE K2AOU, etc. Then, hit Start #7 as many times as you want the message! Program your Digital Group "GO TO" or "Execute" (Start) locations as follows:

005	112	300	#5	GO
005	113	001		
005	114	300	#6	GO
005	115	007		
005	116	363	#7	GO
005	117	007		

KEYBOARD STROBE LOW ROUTINE (Digital Group Op. Sys.)

Address	Code	Step
002 007	365	Save A
002 010	333 000	Input Keyboard
002 012	376 200	Set Flag
002 014	362 010 002	Strobe High? — yes
002 017	361	Pop A
002 020	311	Return

Note that the TV Erase and TV Writer routines are also part of the Digital Group operating system. The Operations Monitor title page was also moved and condensed to make room for this program. Change the following bytes to move the title page TV editor location:

005 004 041 300 005 Load B&L (With new ASCII message location)

RTTY Test Station

-- complete pattern generator

E. H. Sommerfield W2FJT
49 Spring Road
Poughkeepsie NY 12601

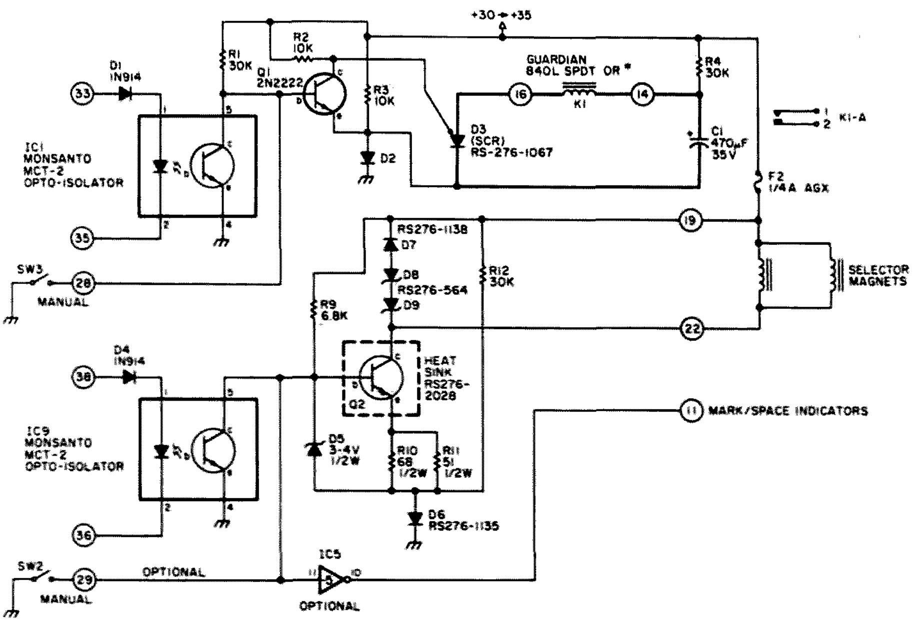

*Fig. 1. Motor control and selector drive. RS = Radio Shack. *Sears, Roebuck garage door opener, model 139.65400, replacement part #160B27.*

This article describes a solid state Teletype control/test system that satisfies the following needs:

For the RTTY amateur:

- A solid state selector magnet driver;
- A low power motor control for standby operation;
- RY test generator for stand alone operation and maintenance.

For the microprocessor enthusiast:

- A solid state selector magnet driver with TTL interface;
- A low power motor control with TTL interface.

The design is modular in that any function can be implemented independently of the others.

Functional Specifications

The "box" satisfies the following needs:

1. Complete electrical isolation between the Teletype and the microprocessor.
2. Computer-controlled on/off motor control.

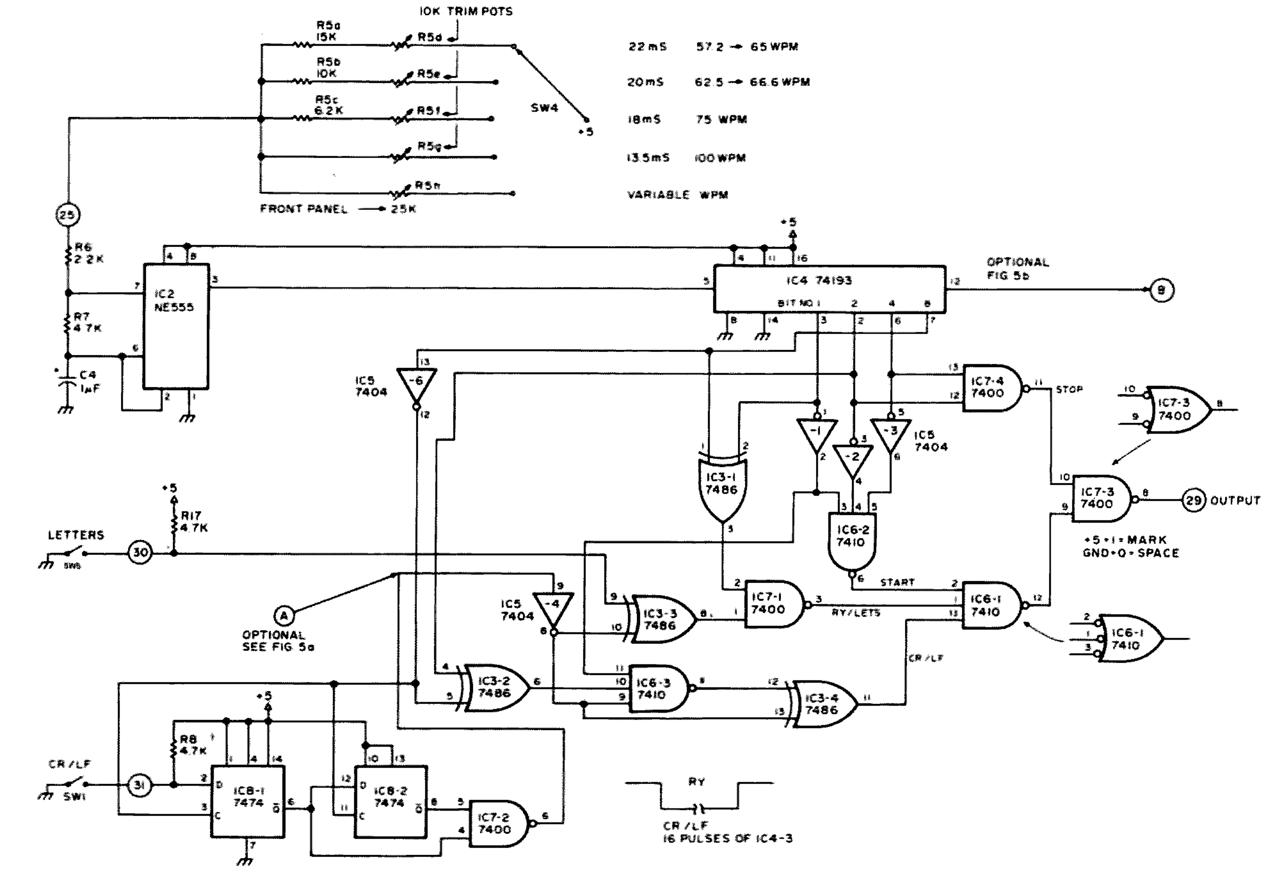

Fig. 2. Test pattern generation.

3. Solid state selector magnet control.
4. Self-contained RY test generator.
5. TTY interface.

Motor Control – Fig. 1

IC1, an optoisolator, is normally in the off state. Q1, normally in the on state, holds D3 (the SCR) in off state. C1, the power storage capacitor, has charged to +30 V via R4; this takes about 15 seconds. The steady state current is about 8 mA.

When 10 mA is applied to IC1 pins 1 and 2, IC1 turns on, driving Q1 off. This permits 3 mA of gate current to flow into D3 via R2. D3 turns on, discharging C1 through the motor control relay K1. K1 is a mechanically latching relay. Each successive pulse changes its state; if it is on, it is turned off; if it is off, it is turned on. The stored charge in C1 is sufficient to energize K1. When the charge on C1 is dissipated in K1, K1 de-energizes and the anode current on D3 drops to 1 mA (via R4), which is insufficient to maintain conduction in D3 and D3 turns off. There is no inductive kick on K1 since no current exists in K1 at the time of turnoff. This condition will last until the 10 mA is removed from IC1.

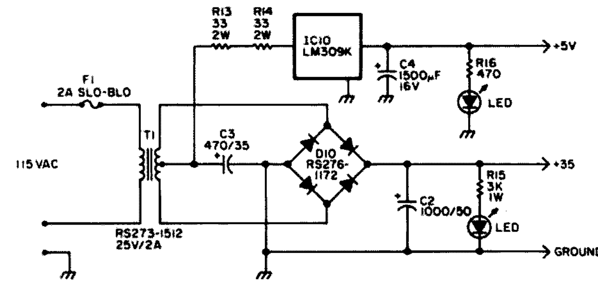

Fig. 3. Power supply. RS = Radio Shack.

A waiting period of 15 or more seconds must be observed before another action can be initiated in order to recharge C1 at a power supply voltage of 35 volts, 25 to 30 seconds at 30 volts.

Note the connection of C1 to D3 must be direct and as short as possible since there are 3 Amperes of pulsed current flow in this loop.

D1 is used to prevent damage to the optoisolator in case the wrong polarity is applied to pins 1 and 2 of IC1.

D2 is used to bias Q1 high enough to insure that IC1 turns off Q1. Manual control is achieved by turning off Q1 via SW1.

Test Pattern Generator – Fig. 2

A test pattern that generates letters R and Y (or numbers 4 or 6) is stimulated by IC2, a free running oscillator. IC2 generates positive transitions at a rate determined by R5a-R5h and SW4. These rates range from one each 22.0 ms (60 wpm) to one each 13.5 ms (100 wpm), or at a variable rate determined by R5h.

The function generation logic is divided into five functional areas: START, STOP, R(4)/Y(6), CR/LF, LETTERS. The START logic IC6-2 provides a down level at the output when the timing generator, IC4, is at 000x (outputs 1, 2, 4, and 8, respectively) START time. Note "x" is a don't-care condition. The STOP logic IC7-4 provides a low pulse at the output when the timing generator, IC4, is at 011x or 111x STOP time. The following explanations are only concerned with the 1-5 Baudot bits; the start and stop bits are common to all test patterns.

Letters

The LETTERS feature

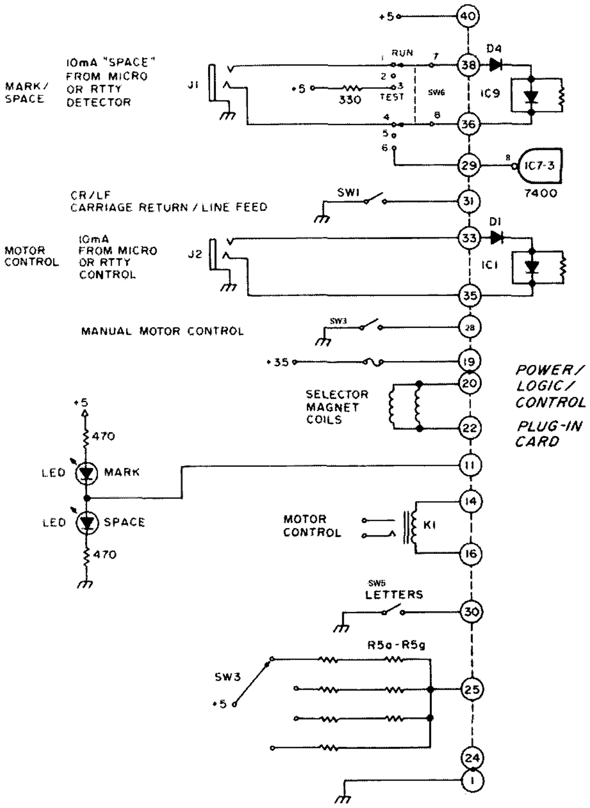

Fig. 4. Interconnections.

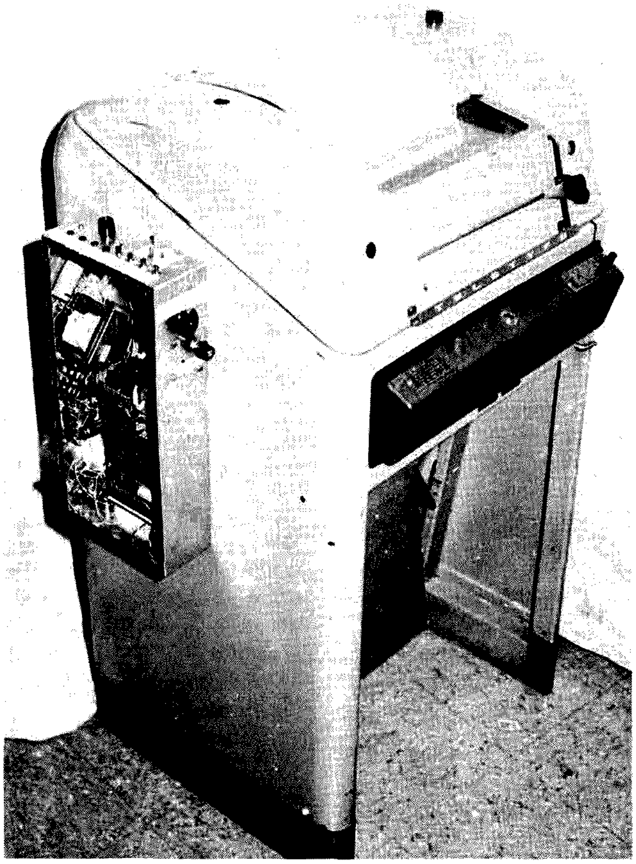

Solid state Teletype control/test system.

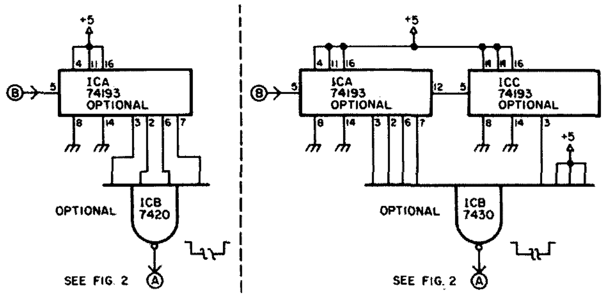

Fig. 5. Optional automatic CR/LF. (a) 30 character line. (b) 62 character line.

came essentially free. Since one section of IC3 was still unused, it was wired in using only an additional pushbutton and a 4.7k pull up resistor. Unfortunately, the FIGURES function would have required more than the simple implementation of that required for LETTERS, and since both LETTERS and FIGURES are "wants" versus "needs," I decided to get along without the FIGURES function.

RY(46)

RY(46) is generated continuously, but is only applied to the output when IC7-1 is high (no CR/LF). "R" is derived from bit 1 being high, and "Y" is derived from bit 1 being low. This is accomplished by exclusive OR logic IC3-1, controlled by bit 8.

CR/LF

Carriage return is executed before line feed to allow the maximum amount of time for the carriage to return before RY printing resumes. CR/LF is generated when IC6-pin 9 is high (CR/LF). As in the RY generation, timing pulses are combined in IC3-4 to provide CR/LF.

Timing bit 8 controls whether CR or LF is generated by inverting timing bit 2 via IC3-2. IC3-4 is required to provide the proper polarity of signals at IC6-pin 3 when generating CR/LF vs RY.

Character/Line Control

IC4 generates 16 timing pulses – 8 for sequence 1 (8 bit low) and 8 for sequence 2 (8 bit high). There are three alternatives that can be used to control the number of characters/line. The manual control is shown in Fig. 2. Two optional automatic controls of 30 and 62 characters/line are shown in Fig. 5.

The common requirement is that the negative CR/LF

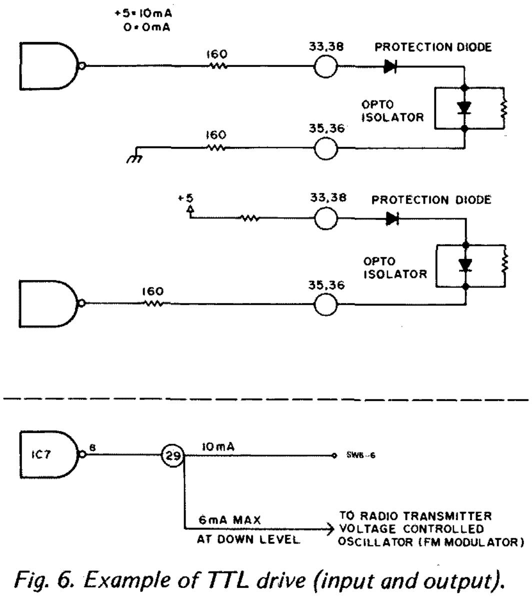

Fig. 6. Example of TTL drive (input and output).

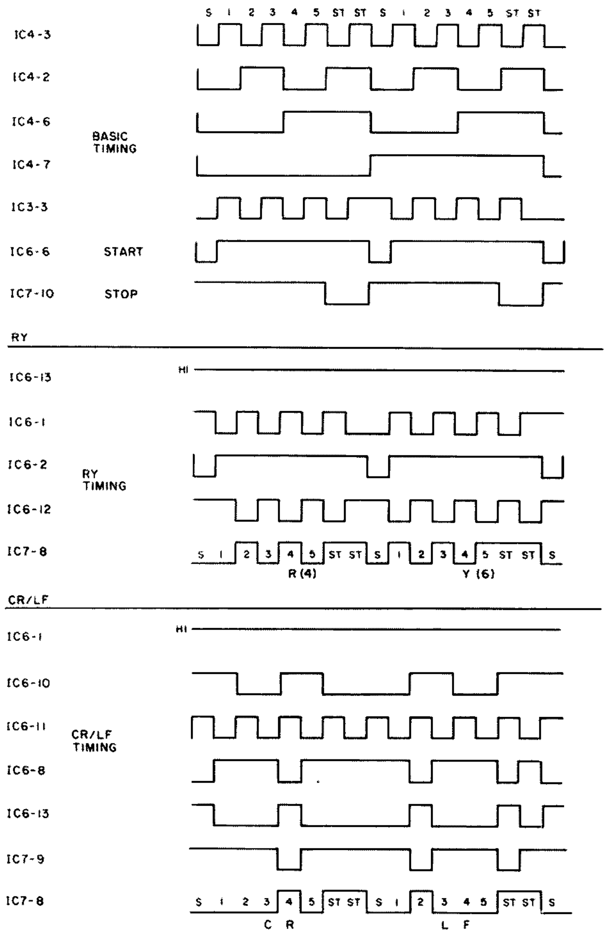

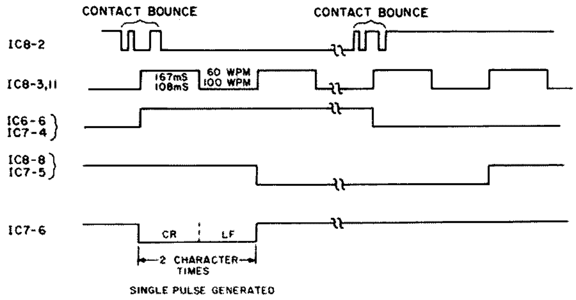

Fig. 7. System timing diagrams.

gating signal start at the beginning of CR and end at the end of LF. This is accomplished in the manual configuration by clocking the pulse generator IC8-3,11 with bit 8 low. It is implied in the automatic generator ICA and ICB (Fig. 5) since ICA is controlled and synchronized by IC4. Since ICA increments one for each 16 bits of IC4, each ICA count equals two printing characters. ICA and ICB provide a count of 16; this results in 30 characters plus CR/LF for a total of 32 characters. ICA, ICB, and ICC provide a count of 32; this results in 62 characters plus CR/LF for a total of 64 characters.

The automatic CR/LF circuits in Fig. 5 can be used by disconnecting at points "A" and "B" in Fig. 2 and connecting in one of the circuits shown in Fig. 5.

The selection of the mode and number of characters/line is strictly an economic and space choice.

Selector Magnet Driver – Fig. 3

IC9, an optoisolator, is normally in the off state. This permits 4.7 mA to flow into D5 and the base of Q2 via R9. The voltage across R10 and R11 is clamped via D5, minus the base to emitter drop of Q2, to about 3 volts. This fixes the voltage across R10 and R11, and thereby the current through Q2, independent of the collector voltage variations of Q2. This value should be trimmed via either R10 or R11 to 60 mA.

The "Pick" current level of the selector magnet coils in the 60 mA configuration is about 35 mA (the "drop level" is about 25 mA). The measured time to reach this value, in this circuit, is about 2.3 ms. This compares favorably to the calculated time of 2 ms in the original high voltage circuit. The driver has operated at a 100 wpm rate with a power supply voltage as low as 20 V.

D4 is used to prevent damage to the optoisolator in case the wrong polarity is applied to pins 1 and 2 of IC9. Note that the selector magnet coils are connected in the 60 mA loop configuration (Fig. 1).

Power Supply

The power supply is a dual voltage configuration supply, +35 volts at up to 1 Ampere and +5 volts regulated at up to 500 milliamperes.

The approximate current loading is about 160 mA at +5 volts and about 80 mA at +35 V. R13 and R14 are used to reduce the power dissipation on IC10.

Adjustment Procedure

1. Preliminary 60 mA Mark Adjustment

Remove F2 and place a milliammeter across the F2 contacts.

Adjust the MARK current to 60 mA by trimming R10 or R11.

Replace F2.

2. Frequency Adjustment

Scientific Method:

Set the range selector to 50.

Place a scope probe on the collector of Q3.

Adjust R5d-R5g until the voltage glitch, caused by the movement of the selector magnet, appears at the trailing edge of each MARK voltage waveform.

Brute Force:

Set the range selector to 50.

Adjust R5d-R5g until Rs (or Ys) are being printed.

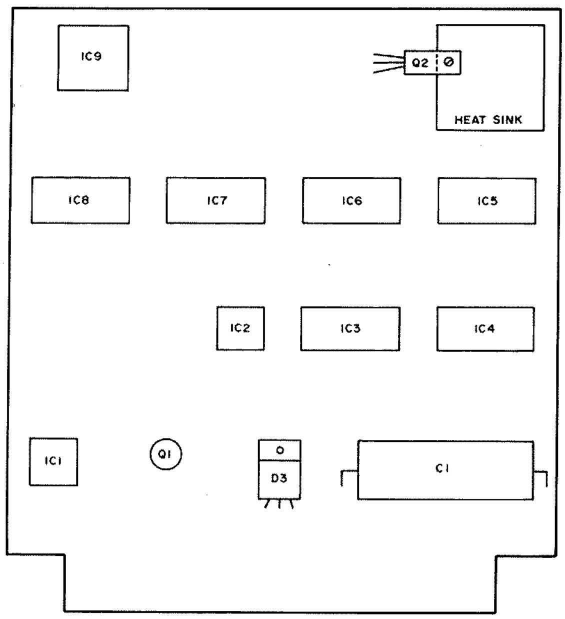

Fig. 8. Board layout used at W2FJT.

Rock R5d-R5g until they are in the center of the range.

Operation

1. Test

Place mode switch in TEST position.

Press SW3 to start motor.

If manual CR/LF is implemented, press SW1 and hold for at least 1/2 second to ensure a CR/LF.

2. Automatic

Plug mark/space signal line into J1.

Plug motor control line into J2.

Provide a current pulse, with at least 10 mA to control each of the functions (Fig. 6).

Construction

I implemented the manual CR/LF configuration, since my Model 28 had automatic CR/LF, together with the selector magnet driver and power control relay driver, on a single card. If I had to construct the whole thing again, I would build the power circuits on one card and the logic on a second card. This would leave sufficient room for the automatic CR/LF circuitry if desired.

The physical layout is arbitrary except to keep the high current motor control relay (K1) loop direct and short.

Both Q2, the selector magnet driver, and IC10, the +5 V regulator, must be heat sinked. Note that the heat sink tab on Q2 is not electrically isolated from the collector and, therefore, the heat sink must be insulated from the chassis.

Conclusion

The low power drain, electrical isolation, reliability, and testing versatility offered by this control/test system makes it a valuable addition to either a computer or a radio-controlled Teletype installation. It has been at W2FJT. ■

The World's Cheapest Calibrator

-- works on 2m!

Having trouble netting your transmit crystals on your 2 meter handie-talkie or transceiver? Can't buy or conveniently borrow a frequency counter to do the job? Then read on about a $10 solution . . .

With today's proliferation of sensitive, narrow band repeaters, it is increasingly important to be right on frequency to obtain maximum range and good audio quality from your own gear when "making the system." Even when operating simplex the tolerant wide band receivers are rapidly disappearing. Most would agree equipment should be within about ± 1 kHz of the nominal channel frequency for optimum results.

I got tired of borrowing a frequency counter every time I put new rocks in my equipment or changed the channel locations of some of them. Couldn't see putting out $100 or more for a frequency counter. One day while tuning my low band receiver with its stable 1 kHz calibration, the idea hit me. Add a 2 meter converter to it! So what if the low band receiver is for SSB-CW and my 2 meter gear is FM? The frequency of the unmodulated FM carrier would be just as recognizable as a continuous CW signal.

In looking around for a 2 meter converter for my Heathkit SB-301 low band receiver, I discovered Heath Company no longer made the Model SBA-300-4 2 meter converter. However, I picked up a used one in the flea market for only $10! The Heath Model SBA-300-4 2 meter converter output is a 28-30 MHz signal that is inputted into the four SB-301 half megahertz 10 meter band increments. With the proper crystal in the converter, any 2 MHz segment of 2 meters is tunable with 1 kHz resolution on the SB-301. Other 2 meter converters are available or you can build one yourself from the literature.

Netting 2 meter crystals is a snap now. First, check the calibration of your receiver and converter. You can verify it by comparing it to the output frequency of one or more of the accurately calibrated repeater stations when keyed by an unmodulated FM carrier with the receiver in the CW position. Use a minimal antenna or back off the rf gain if necessary, so your receiver is not overloaded and the S-meter reaches a maximum without pinning the needle. Reset your receiver dial hairline if required for accurate calibration.

The actual netting of your 2 meter crystals is simple. Feed your transceiver, preferably into a dummy load. Turn your low band receiver audio gain down to minimum to prevent audio feedback. Use little or no receiver antenna or reduce rf gain if necessary to avoid overloading. With the low band converted receiver set to the desired 2 meter frequency, adjust the netting capacitor for maximum S-meter reading by alternately keying and adjusting the 2 meter gear. Double check your work by varying the receiver frequency slightly while keying your unmodulated 2 meter transceiver. The S-meter reading should peak sharply at the desired frequency, especially with the receiver in the CW mode.

I've found I can get to within about ± 1 kHz using the above . . . and for $10 that's a good bargain! As a bonus, a low band receiver-converter can be used to receive FM (somewhat poorly though) in an emergency by detecting it off the bandpass slope in the low band receiver. ■

Fig. 1. Character set.

The classic RTTY receiving setup consists of a terminal unit to change RTTY tones to dc pulses and a teleprinter which mechanically decodes the pulses and displays the resulting message. The KIM-1, which many hams are using today, has those elements. All that you need is the proper program and one simple connection between the station receiver and the KIM-1, and you will be displaying RTTY on the seven segment readouts. The displayed character set may take a bit of getting used to, but can be read with surprising ease. For instance, there is no way to get a perfect "Z" into a seven segment readout, but the displayed character "≡" becomes recognizable easily enough when read in context. The idea for this sort of readout is not all mine, but was developed simultaneously by several KIM-1 users. I have tried to put together a fairly uniform and sensible character set, however. This character set is shown in the program listing starting at address 0300.

At this point, you might ask how much can be read using only 6 displays. Surprisingly, most words longer than 6 characters can be easily read with almost no practice, proving, I suppose, that you really don't need all those letters anyhow.

As the terminal unit, I use the KIM-1's own tape interface circuit. This is a 565 phase locked loop and op amp buffer connected to an

I/O port. While it is no Mainline ST-6, it will give adequate performance on strong wide shift signals.

The first part of the program (see Fig. 6) is an adjustment loop to aid in setting the TU properly. A low tone should light all segments of the left data digit (displays an 8); a high tone will light the right digit. On some receivers (like mine) that are response limited because of sideband filters, it may be necessary to adjust the KIM-1's pot (VR-1) to get the TU to operate. Adjust this pot so that the not on digit is completely off. If both digits are lit, it indicates that the PLL is "hunting," and no readable display will result. Ideally the display should appear to be moving from one digit to the other. When you have this display, simply move to the decoder portion of the program by pressing the F button. The characters should start to display themselves on the seven segment readouts moving from right to left.

The microprocessor is doing the same thing as a mechanical decoder. First it waits for the start bit. Then, when it has detected this bit, it delays a set time until the middle of the Baudot start bit. The timer is then set to a different time that will not let the TU look at the data until enough time has elapsed and the middle of the first Baudot data bit is available

Fig. 6. When tuning is satisfactory, as described in text, press button F to start display.

from the TU. When all 5 data bits have been decoded and stored in a memory byte, another memory byte is looked at to see if the upper case/lower case bits are set. With this information, the alphanumeric character may be looked up in the character table and tested to see if it is a character or a command. If it is a character, the data byte is loaded into a display location, and the display is shifted one space to the left. If it is a command (bit 7 set to 0), the command is decoded, and the appropriate action taken. The timer is then loaded with a timeout time which gets the microprocessor out of the last Baudot data bit. When this time expires, it is again time to look for a start bit. The display is run continuously whenever the microprocessor is not busy doing anything else.

For those of you who already have a TU and would like to use only the display portion of the KIM-1, I have included (Fig. 2) the necessary changes to the program to use one of the regular input ports (pin 8) as your input connection.

Since the KIM-1 timer is variable, you can also decode baud rates other than the standard amateur 45.5 baud (60 wpm) that the program is set for. Fig. 5 shows the necessary changes to the timing bits to decode other RTTY speeds. To decide which baud rate applies, measure the length of a data pulse with a scope, then consult the table for the data pulse length which fits and insert the timing bits accordingly. Do not, by the way, expect to decode everything you hear. All that frequency shifts is not necessarily Baudot. Many commercial stations are using ASCII these days and others encrypt. ■

Build A Meter With Class

-- simple field strength device

The manual for my rig suggests that a "better procedure" for loading it up is to use an swr bridge on forward or a field strength meter to peak plate and loading controls for maximum output power. The field strength meter seemed the easy way out, since a bridge costs fifteen dollars. The meter would cost me next to nothing to build considering the present status of my junk box. Therefore, I decided on the junk box approach to measure output power.

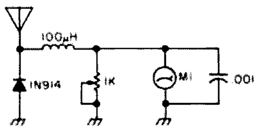

Fig. 1.

While building the field strength meter, I consulted an article in the July, 1976, issue of *73*. The article dealt with building the world's smallest field strength meter. The design given was standard and allowed wide margins for parts substitution. Recently, another ham wrote *73* about an rf choke that cost four dollars, adding that amount to the cost of his otherwise free field strength meter. I just thought I'd mention that all parts in my field strength meter came from junked PC boards, with the exception of the meter movement.

When you go scrounging parts for this project, remember about the choke. Anything that will choke rf works. So, substitute freely, but don't change from a diode to a resistor.

As I said, the design is standard, but the antenna is quite unconventional. Instead of using a piece of twelve gauge bare copper or coat hanger wire, I used twenty-two gauge tinned copper wire bent into the form of my initials.

Construction

Select the amount of wire you feel necessary to complete your initials or whatever. Straighten the wire with a vise and a pair of pliers. Starting at the top of the left initial, make a bend to form the beginning of the antenna. Try to use one continuous piece of wire to make the antenna. To insure this, draw your idea on a piece of paper first. If you use one piece of wire the antenna will look a lot better, and you will eliminate having to solder on extra pieces of wire. The joints make bulges in the antenna which just don't look as nice on the finished meter. Solder a few spots to hold this thing together. While the iron was still hot, I also attached a banana plug.

With the antenna done, I built the guts of the meter. The easiest way to go is to mount the pot and use its terminals as tie points. The wiring is the easiest you'll ever do and is almost impossible to screw up. My only problem was mounting the banana jack, which I solved by using two shouldered washers.

Conclusion

Taking a lead from modern art, you can make just about anything for an antenna on your FSM. You've got to admit, now that we have an alternative, that bare copper does look a bit uncouth! This meter may not be the best or the smallest, but it does have class! ■

Parts List

1 diode, 1N914 or just about anything else
1 50 uA meter
1 rf choke
1 pot, 1k or thereabouts (I have a 500 Ohm)
1 .001 uF capacitor
1 mini box
1 banana plug
1 banana jack
2 shouldered washers
Plenty of twenty-two gauge wire

FSK for the FT-101

-- a simple mod for RTTY

The Yaesu FT-101 series transmitters (FT-101B, E, EE, and EX models) have now passed the 200,000 mark in production and are in use all over the world. Therefore this article is to show you how to easily convert these transceivers for teletype service.

The schematic in Fig. 1 is set up for "dry keying" and supplies 7.5 volts to the keyboard or tape reader. One word of warning: Do not apply voltage from a keyer or you will fry the components. You might mount all of the parts involved in a minibox. Put a jack in one side to plug in the keyboard. The potentiometer can be mounted in the minibox and is used to set the shift which is adjustable from 850 Hertz to less than 170. The latter shift is generally used on the HF bands while 850 Hertz is still heard on VHF, at least in the Los Angeles area.

The connections from the FSK device to your FT-101 are just three in number, with one going to the above ground side of the 3179.3 kHz crystal on PCB 1184A. Another lead goes to PCB 1314A, pin 14, which leads directly to the IC, Q4MFC6034A. The third lead is strictly a ground connection between the minibox chassis and the transceiver chassis. One side of the keyboard jack goes to this ground in the minibox as well. I would suggest that for this purpose a two wire shielded cable be used, between the minibox and the transceiver.

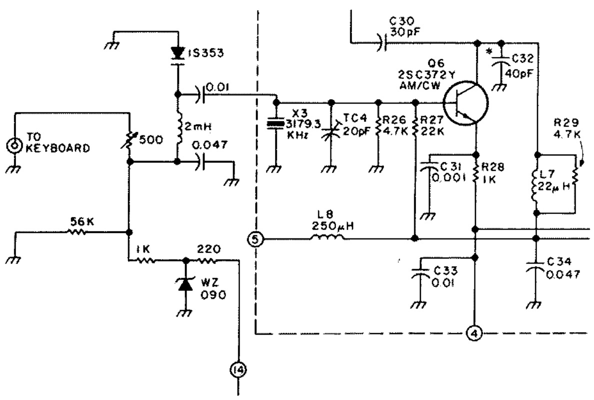

Fig. 1.

You will find that if you flip from one band to another you may have to readjust the "pot" to maintain your shift. Once done on each band by checking with the receive station, you can apply decals or scribe the box, however you choose, for resetting to each band. Obviously you want a pointer knob on the pot shaft for this purpose. If you are a purist, you could measure the pot resistance required for the shift used on each band adjustment of the pot and use fixed resistors of the correct accuracies instead. This would then require a switch in place of the pot and, by rotating the switch, you would then be able to move from one band to the other. The switch, of course, would have to have the correct number of positions for whatever number of bands you will be doing your RTTYing on.

All the components used in the FSK circuitry are garden variety parts found in any ham supply house or electronics store. Assembly time may take as long as an hour or two, depending upon your experience and whether or not you accidentally pick up the soldering iron by the wrong end while working.

Tune-up of the transceiver would be under AM loading conditions, as teleprinter operation is the same as CW (keydown), and the surest way to cause your transceiver to self-destruct would be to ignore this fact.

There seems to be quite an upsurge in teleprinter communications among radio amateurs these days. One of the reasons, perhaps, is that your friendly surplus store makes them available for as little as $25. This would be for the RTTY workhorse, the good old Model 15, which is a page printer, send and receive. Prices vary in the various stores as might be expected. "Big Daddy," the Model 19, generally can be located for under $100, and this provides for punching and transmitting tape while waiting for the other guy to stand by or for calling CQ, and thereby impressing people with your keyboard finesse until the tape runs out and you resume "hunt and peck."

These machines normally are found with synchronous motors and 60 word per minute gears; however, sometimes they are equipped with governed motors and 75 word per minute gears. Stay away from this type of machine, as these governed motors are noise generators and ham communications are at the 60 wpm speed (even though you don't type that fast).

Be seeing you on the green keys! ■

Build A Drift-free T.U.

-- a quality RTTY demodulator

Since I have an old HRO-60 receiver which has a lot of drift, and since I wanted to copy RTTY with it, I had to find a circuit which would be easy to tune and compensate for the drift. I also required the facility to reverse the mark-space sense when coupled to a transceiver.

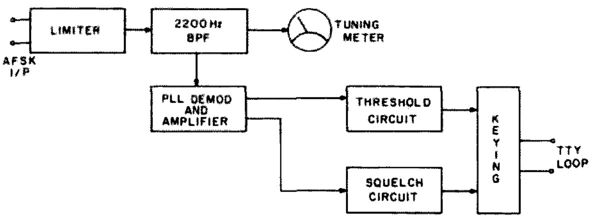

Fig. 1. Block diagram of RTTY demodulator.

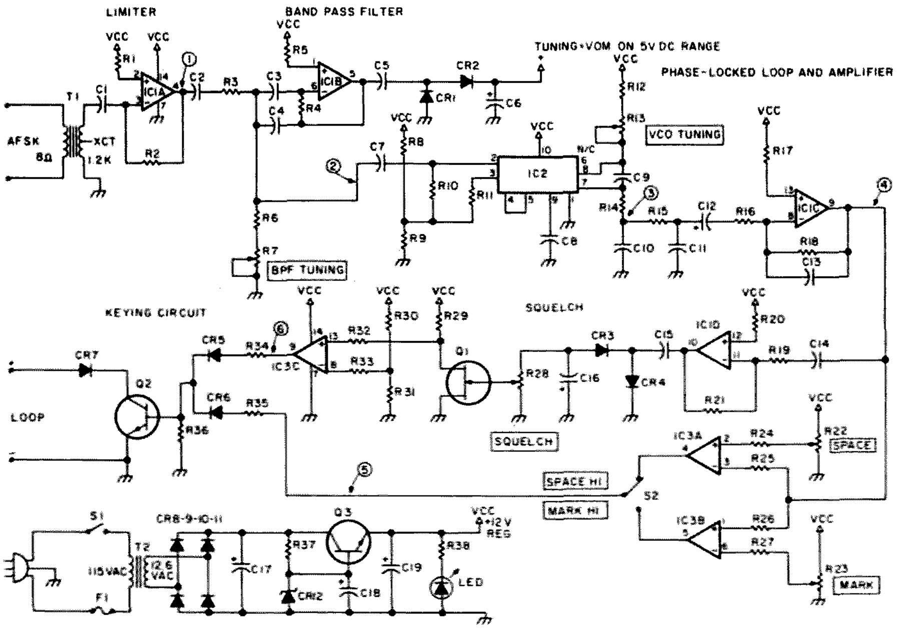

Fig. 2. Schematic.

The following circuit which was developed has the following characteristics:

1. Narrow shift detection;
2. Easy to tune;
3. Reversible sense;
4. Good signal to noise characteristics;
5. Auto mark-hold;
6. Easy to obtain parts;
7. Easy to adjust.

Block Diagram Operation (see Fig. 1)

Limiter: The audio from the receiver is hard limited to compensate for fading signals. The limiter will operate at approximately 1 volt peak-to-peak input and applies an 11 volt peak-to-peak square wave to bandpass filter.

Bandpass Filter: This has a center frequency of 2210 Hz and a "Q" of 10. The purpose of the filter is to improve the signal to noise ratio and to discriminate between close signals. There are two outputs: the high level output is used for the tuning indicator and the low level output is applied to the phase locked loop demodulator.

Phase Locked Loop: An LM565 is used to convert the AFSK tone to a varying dc level. The dc level is approximately +10.5 volts and changes by 50 mV in step with the mark-space shift. An amplifier stage is required to increase the shifted level to approximately 11 volts peak-to-peak. This is applied to two circuits, the threshold circuit and the squelch circuit.

Threshold Circuit: Consists of two comparators which determine if the shift meets predetermined limits. The outputs of the comparators are connected to an SPDT switch to enable sense selection. The comparator circuits are used to differentiate the amount of shift on a noisy signal and a good signal.

Squelch Circuit: Noise for the squelch circuit is derived through a differentiator from the phase locked loop amplifier. The noise is rectified,

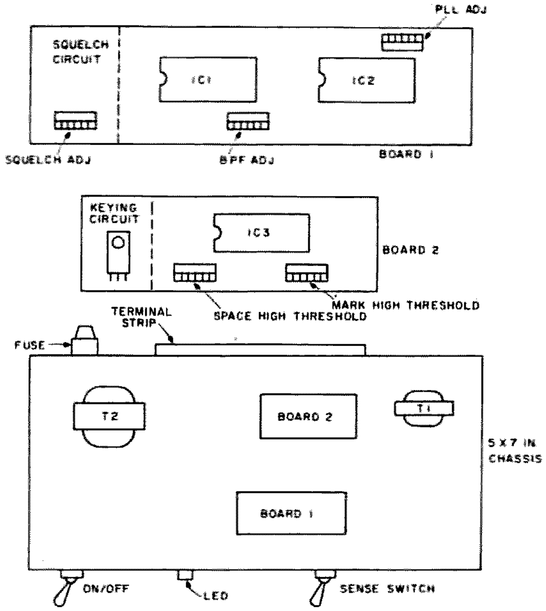

Fig. 3. Layout.

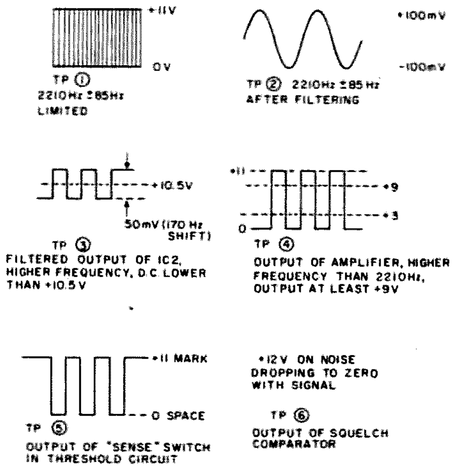

Fig. 4. Test points.

and controls an FET which produces a dc level which is +12 volts on noise. This is to prevent the teleprinter running "open" on noise or static crashes.

Keying Circuit: The output of the threshold circuit is applied via an OR gate to the keying transistor. The output of the squelch circuit is applied to a comparator which is used as a switch to disable the keying signal from operating the keying transistor. If the noise is greater than the signal, the keying transistor will continue to conduct, causing a mark-hold configuration. If the signal is greater than the noise, the squelch output goes LOW, enabling the keying transistor to follow the mark and space levels from the threshold circuit.

The schematic diagram is seen as Fig. 2.

Construction

The complete demodulator was built on two IC type Vero boards with a layout similar to Fig. 3.

The sense switch, +12 volt regulated power supply, and the input transformer were mounted on a 5 x 7 aluminum chassis with a terminal strip on the back. The two circuit boards were mounted on the top of the chassis to enable easy adjustments.

Adjustments

The following test instruments are required:

VOM or VTVM;

Dc coupled oscilloscope;

A tape recorder with a good recording of AFSK tones.

(This can be a recording of the output of an AFSK keyer, which can be obtained from your local RTTYer.)

Bandpass Filter Tuning: With the AFSK signal fed into the demodulator, adjust the bandpass filter tuning until maximum smooth deflection is seen on the tuning meter.

Phase Locked Loop: If you have a counter, set the VCO frequency for 2210 Hz at the junction of pins 4 and 5 of the LM565. If you do not have a counter, do the following: Connect a dc scope to the junction of the 1k Ohm resistor and the .47 uF capacitor at the output of the LM565. Adjust the scope so that there is maximum vertical gain and the dc level can still be seen. Use the vertical position control. (*Note: Do not use ac coupling.*) Adjust the VCO frequency until the dc level remains constant

5 x 7 chassis, terminal strip, #6-32 nuts and bolts, insulated spacers for #6-32 to mount boards on chassis, holder for LED

with and without the AFSK input signal. You should also see the 50 mV shift in time with the mark-space frequencies.

Threshold Detector: The SPACE threshold potentiometer wiper should have +9 volts dc to ground, and the MARK threshold potentiometer wiper should have +3 volts to ground. These can be readjusted from on-the-air signals for minimum distortion and glitching of the copy.

Squelch Circuit: Connect the demodulator to the receiver and the teleprinter loop circuit. With the receiver picking up noise, adjust the SQUELCH level potentiometer until the machine just stops printing the noise. Different atmospheric and domestic noise may require more or less squelching action.

Operation

Very simply tune the receiver onto a RTTY signal until the tuning meter indicates a maximum. The teleprinter should start printing. If the copy is garbled, switch to the opposite sense. Fine adjustments may be required to the threshold circuit to produce glitch-free copy, but I found the +9 volt and +3 volt levels to be good enough.

Conclusion

This demodulator has been in operation at my location for over 4 months. It has copied very well through the local line interference and fading of the 20 meter band. With the Swan 350, on 20 meters I use MARK HIGH, and on 80 meters I use SPACE HIGH. The waveforms in Fig. 4 can be seen at the points indicated during normal operation of the demodulator. ■

Noise Rejector

- - great for CW or phone receivers

S. T. Rappold WB6ZYK
PO Box 4678
Redway CA 95560

Here is another version of the outboard noise and interference-rejecting circuit for both phone and CW. It is an accessory aid to even the most modern of receivers. The unit is widely variable and flexible, doing a real job under difficult on-the-air conditions for which the unit was designed.

Throughout my more than forty years of hamming, I have tried many types and combinations of both simple and complex filter circuits, to find that indeed they all do some specialized job. But this circuit has proven to be simple, most effective, and a pleasure to build and use, providing much-needed QRN-QRM rejection and cutting background noise to almost nothing. Of equal importance — it is cheap and dirty. No doubt every ham has the components in the junk box, or can get them at the local electronics surplus store. This simple and straightforward circuit produces surprisingly effective results. The unit has only three controls: a 4-position rotary switch to select desired combinations of the noise-limiting diodes, an af filter notch control, and a tone control.

The unit is to be plugged into the receiver's headphone jack; the unit's output jack can take either phones or speaker. The circuit input begins by cutting sharp and heavy noise pulses in three steps with the 4-position rotary switch. The three diode combinations handle progressively more severe noise pulses.

This is followed by the af filter, which is simply an af T-notch circuit, a smoothly adjusting type, being quite effective in limiting the af passband over a sufficient range for both phone and CW uses. This filter is without any of the ringing of some filter types. The inductor is an 88 mH toroid, a common item. This part of the unit is also noise-limiting.

The filter is followed by an audio peaker circuit in order to overcome insertion losses of previous circuitry. The peaker restores the audio level back up to desirable level.

The output of the unit incorporates an old-fashioned and long-employed circuit to cut still other types of noise and adjust and clear up received signal problems: an ordinary tone control circuit. It is remarkable how much this simple circuit modifies signals and atmospheric conditions.

Try this simple unit on the workbench some evening, and see if it isn't a delightfully cheap and dirty way to enhance receiver performance and utility. Its noise control makes possible 160 meter operation all through the QRN season of the year, and I have been able to stay on the air on 160 in particular when others QRT because of atmospheric and Loran QRN and heavy QRM.

The unit is housed in a 6" x 3" x 2½" utility box. ■

RTTY CRT Tuning Indicator

-- still the best method

Tuning your receiver until the teleprinter stops printing Greek and starts printing English is one way to tune in a RTTY signal, but it obviously leaves much to be desired. The ST-6, with its "plus-plus" tuning meter, is a step in the right direction, but valuable information is lost using this method. One of the oldest, and still one of the best, methods makes use of a CRT display.

With the aid of the CRT display, one can tell at a glance if the station is narrow or wide and, with a little practice, can estimate how wide or narrow the station might be. In addition, the display depicts possible trouble with the discriminators in the demodulator. For example, if either the mark or space LC tuned circuits have changed, believe me, you'll be the first to know. If the other station is transmitting upside down signals (mark and space frequencies reversed), the CRT display will show this condition vividly. The phenomenon of selective fading, in which one signal, mark, or space is attenuated more than the other, is also readily seen. In addition, the CRT display is an excellent coarse tuning indicator. It enables one to tune in a station rapidly and then to fine adjust the signal using the ST-6 tuning meter. In general, the ST-6 tuning meter and the CRT display are not redundant – they actually complement each other.

Theory

Before we go into a description of the circuit, it would be wise to give some background information.

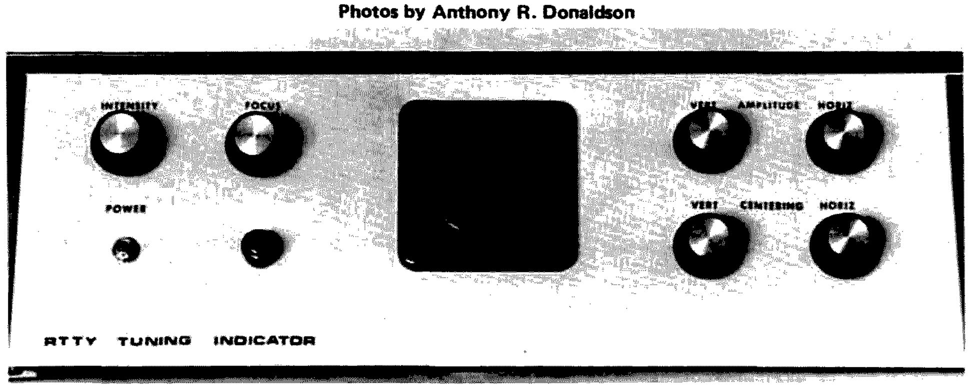
By convention, the mark signal is displayed horizontally, and the space signal is displayed vertically. There is, of course, no particular reason why the mark signal could not be displayed vertically and the space signal displayed horizontally.

A theoretically perfect display would show the mark signal as a perfectly horizontal straight line. The space signal would be shown as a perfectly vertical straight line. In the real world this is hardly the case. Because the bandwidth of the mark and space tuned circuits is rather broad, at least in the case of the ST-6, some of the mark signal gets into the space tuned circuit. The result is two ellipses rather than two straight lines. For this reason, when tuning in a station, one should ignore the minor axis or width of the ellipse and tune the receiver for maximum amplitude of the major axis.

Theoretically, these ellipses would be perpendicular to each other. Returning to the real world once again, we find this is not the case. Because there is a phase difference between the mark signal induced in the mark tuned circuit in the demodulator and the same mark signal induced in the space tuned circuit, the major axis of the mark ellipse is not horizontal. For the same reason, the major axis of the space ellipse is not vertical. In my case, I have found the major axis of the mark ellipse to be approximately -30 degrees off the horizontal axis and the major axis of the space ellipse to be approximately 20 degrees off the vertical axis. It is possible to add additional filtering to both the mark and space signals to approach the "perfect" condition of two perpendicular straight lines; however, this detracts from the display because one loses information in the process. For example, if the tuned circuits in the demodulator should shift slightly, chances are the display will not see the shift because of the extra filtering.

When constructing this project, you should be aware of one possibly critical point. Stray magnetic fields may deflect the spot, making it impossible to focus the spot to a fine point. For this reason, care should be exercised to keep the CRT as far as possible from transformers, especially the filament transformer. If you should be unable to focus the spot to a fine point, wrapping the CRT in iron or steel of high permeability should alleviate the problem. Tube type demodulators, such as the TT/1, will not require additional amplification to drive the CRT. However, more and more amateurs are building solid state demodulators such as the ST-6. The nominal mark and space

Photos by Anthony R. Donaldson



CRT RTTY tuning indicator.

signal from one of these units is 1.5 volts, hardly enough to drive the deflection plates of the CRT, which typically require a 30 volt signal for full face deflection. The objective, then, is to provide enough amplification to drive the CRT. There is, however, one other requirement of the design; it must have an extremely high input impedance. The reason for this is simply to prevent the loading of the mark and space discriminators in the demodulator. Fig. 2 shows the 741 operational amplifier connected as a noninverting buffer amplifier. In this configuration it will provide a modest voltage gain of 2 and have an input impedance well above 100 megohms. If the output from the demodulator is much less than 1.5 volts, additional amplification may be required. This is easily accomplished by changing the 47k feedback resistor connected between pins 2 and 6 of each 741 amplifier to 100k to obtain a gain of 3, or to 150k to obtain a gain of 4. The output of the 741 is capacitively coupled to a high voltage amplifier used to drive the CRT. This stage makes use of a high voltage transistor and, installed in the circuit, exhibits a voltage gain of 10. From there, the signal is applied to the electrostatic deflection plates of the 2AP1-A CRT. The 2BP1 is another CRT that works well in this application; however, it is not pin for pin compatible with the 2AP1-A.

High Voltage Power Supply

The high voltage power supply schematic shown in Fig. 3 provides the necessary voltage (270) for the deflection plates of the CRT, as well as the voltage (130) for the high voltage amplifier. The voltages are not critical, but is important that the ripple voltage be low. The supply is connected as a simple half wave rectifier with a goodly amount of capacitance on the output to reduce ripple.

Low Voltage Power Supply

If you have an ST-6, you can use the plus and minus 12 volt power from it like I do. Should this not be the case, Fig. 4 shows a power supply that may be used.

Adjustments

Turn the power on and, assuming there is no smoke, ascertain that the focus, intensity, and centering controls are working properly. Since there is no signal at this time, only a simple spot should appear on the CRT face. As previously mentioned, inability to focus the spot to a fine point may be indicative of stray magnetic fields.

Connect a voltmeter to test point 1 (T.P.1). If the voltage is not 65 volts (one half of 130), try different values of RV until the T.P.1 voltage is 65 volts. The purpose of this step is to center the signal so that it will be able to swing equal amounts on either side of this reference. If the bias were not set in this way, one side of the sine wave would be clipped, causing distortion. An identical procedure should be used for T.P.2. Different values of RH are used, until the voltage at T.P.2 is 65 volts. I found RV to be 150k, and RH to be 180k in my unit.

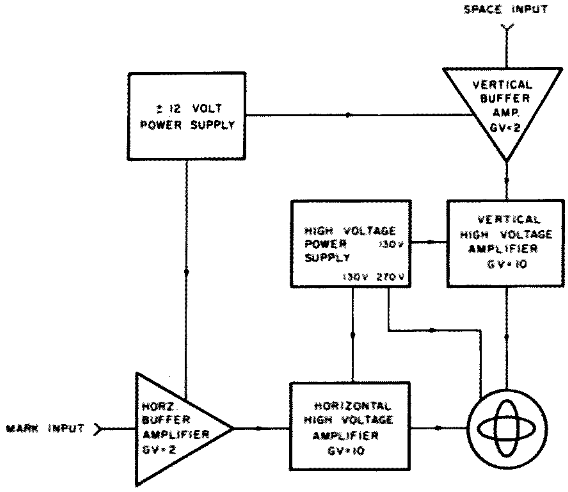


Fig. 1. Block diagram.

In case you have gotten used to working on circuits with the power on, because they were low voltage circuits (e.g., TTL circuits), I wish to remind you that the voltages in this unit are lethal. Turn the power off, and make sure the energy stored in the capacitors has dropped to zero before trying new values for RV and RH.

The next step is to position the CRT properly. This is accomplished by supplying a one volt audio signal (approximately 2 kHz) to one input and then the other. One should find a straight line is produced in each of these tests and that they are perpendicular to each other. The purpose of this step is to identify the position of the vertical and horizontal deflection plates. With the power off, rotate the CRT so that when the signal is applied to the mark input, the straight line on the CRT face is horizontal.

Tuning with a Scope

Tuning with a scope is a quick and simple process. The vertical and horizontal amplitude controls may be set by the individual to produce a display that nearly fills the face of the CRT screen; however, the two controls should be set to

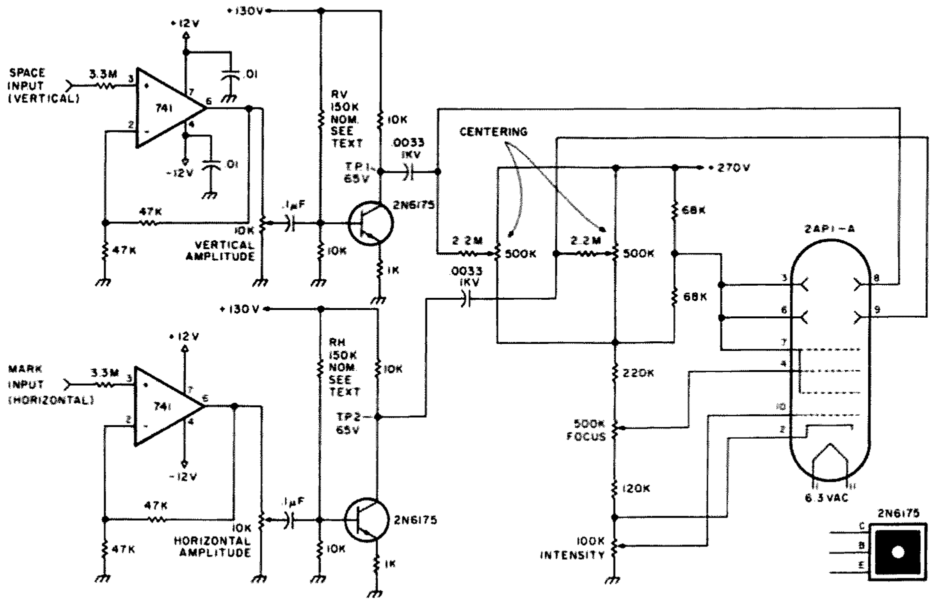

Fig. 2. CRT RTTY tuning indicator circuit.

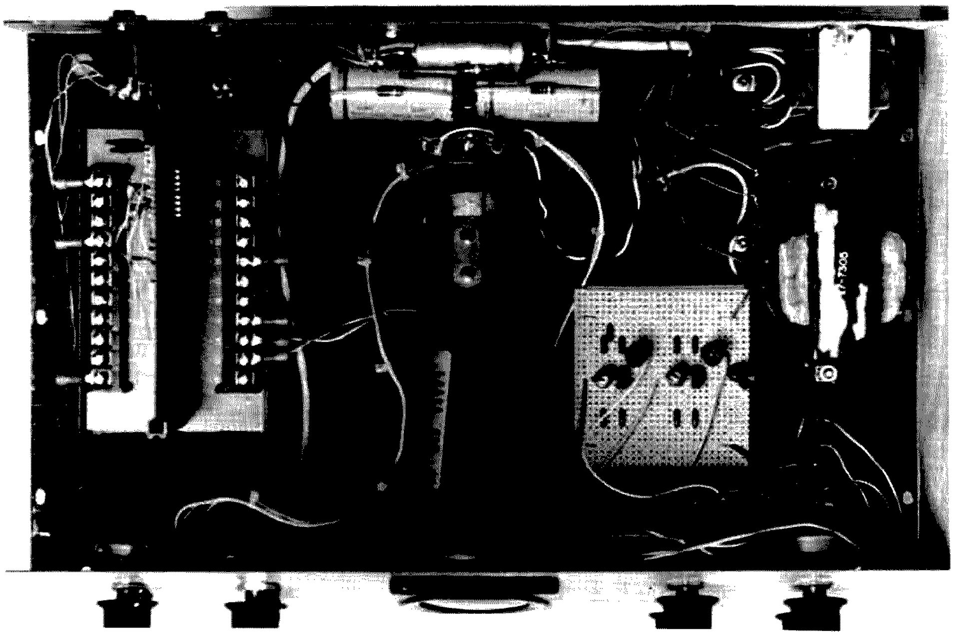

The high voltage amplifier is located on the perforated board. The low level buffer amplifier is constructed on a PC board and is shown in the card holder. The low voltage power supply is not shown in this photo.

identical positions to give an accurate display. As previously stated, one should tune for the maximum amplitude of the major axis of each ellipse. If the shift of the station and the discriminators are identical, both amplitudes will peak at the same time. If the station is wide of narrow, one should tune for equal amplitudes even though they are not maximized. This method, called straddle-tuning, is perhaps one place where the ST-6 "plus-plus" tuning meter is superior. A typical application of this technique is found in tuning in commercial 425 Hz shift stations with 850 Hz discriminators.

One last note: When you tune in a station, it is best to have the limiter on (FM); once the station is tuned in properly, the limiter may be turned off (AM) if desired.

Conclusion

The CRT RTTY tuning indicator described in this article has been in use for over a year with no problems. The display provides a quick and accurate method to tune in a RTTY station. In addition, this method gives a great deal of information, much more than any simple meter could.■

Cassette-Aided CW and RTTY

- - inexpensive message storage

The "in" thing today is to use IC memories for functions such as routine CQs or special calls on CW, ID functions, RTTY test messages, etc. But, for individual station use, there is still a lot to be said for the use, for these functions, of a compact cassette recorder once it is equipped with the proper interface and signal conditioning circuits to handle digital data. Such recorders are inexpensive, reasonably reliable and can be used for both digital type signals and voice signal recording/playback. Unlike some IC memories where the data in memory is lost when the power is removed, there is no need to reprogram the memory (the cassette) of such a recorder every time it is used. A situation that particularly enhances the use of such recorders is the recent availability of endless loop cassettes at a reasonable price. Although such cassettes were available before from Phillips, they were relatively expensive. But now the Japanese have done it again, and such endless loop cassettes in a variety of loop times ranging from 20 seconds to 12 minutes long are available for $4-$5 from outlets such as Lafayette Radio. The shorter duration tapes (not the 12 minute one!) allow for a CQ call to be made on CW, a pause of 10-15 seconds to check for replies and then more repeats of the call. With a station wired for semi-break in, the operator only has to listen for replies at the right time. The tapes can be used in the same way for a phone station equipped with VOX.

Recording and playing back speech transmission is no problem with a cassette unit, although it is better to use the station microphone rather than a cheap cassette type. Also, it is worthwhile to pay a bit of attention to room acoustics and make the recording as good as possible. After all, the recording need not be made at the station location, but where conditions favor the recording process.

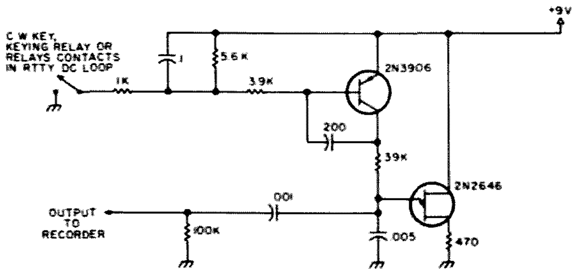

Fig. 1. Signal conditioning circuit for recording produces a keyed sawtooth signal at approximately 5 kHz.

Recording and playing back CW or RTTY transmissions requires conditioning circuits. Poor results will usually be obtained if one just audio records the output of a CW sidetone monitor, for instance, and uses the audio playback to activate a relay. A very good conditioning circuit for CW or RTTY recording and playback appeared some time ago (*Electronics*, April, 1974) and with some slight modifications is shown in Figs. 1 and 2. It has been used with several cassette units with good results. The circuitry has the advantage of using inexpensive components; it may be built inside most recorders and powered from the recorder's internal power supply.

Fig. 1 shows the record mode input circuit. The keyed signal is filtered to remove contact bounce and then it is used to turn on the 2N3906 stage which in turn gates the 2N2646 sawtooth oscillator. The 200 pF between the base and emitter of the 2N3906 is rf bypassing in case a transmitter is also keyed as a recording is made. The 2N2646 operates at about 5 kHz. If this frequency is too high for some inexpensive recorders, the .005 mF capacitor in the gate of the 2N2646 may be raised to .01 mF. The output is fed to a high impedance input or, if the recorder does not have such an input, to a low impedance input via a 470k resistor. In the latter case, it can be permanently left connected since it will not affect voice recordings.

The playback conditioning circuit is shown in Fig. 2. The recorded tone is rectified by the 1N4148 and applied to an

RC timing circuit. The decay voltage developed across this network, when the tone is removed, is used to turn on the 2N3904 and 2N3906 stages. Both transistor base-emitter junctions have 200 pF bypass capacitors across them for rf protection. Keep these leads as short as possible. The output of the 2N3906 stage may be used to drive a reed relay, as shown, or the relay may be replaced by a resistor. The positive voltage across the resistor which is developed during key down periods can then be used to drive the appropriate IC or transistor stages in an electronic keyer. The RC timing combination of .01 mF and 39k should be right for most CW keying and RTTY speeds. However, if clean output keying is not obtained at the speed desired, try varying the RC values slightly.

The total cost for the circuitry described should be on the order of \$5. A few endless loop cassettes, if that type is used, will bring the cost up to \$20 or so. But, it still represents a lot of operational convenience, economy, flexibility and data storage room as compared to IC memories. ■

210 Indian Creek Apts.
Wynnewood PA 19096

A simple frequency synthesizer for use with amateur 2m radios is described below. It features portability, using state of the art CMOS construction, and it draws only 18 mA. A phase locked loop (PLL) is employed to achieve precise high purity output. The entire PLL circuitry includes only five transistors and four integrated circuits for low cost and small size. Most of the required parts are readily available from Radio Shack, including much of the CMOS logic and the circuit board. Coverage of the synthesizer is 140-150 MHz in 5 kHz steps. Frequency input may be obtained directly by thumbwheel or lever switches or indirectly by miniature keyboard and encoder. The keyboard encoder may be built from CMOS chips and includes an LCD readout and scanner. This circuit operates on only 0.4 mA total current draw. The synthesizer described here was built on a single board with favorable results. It draws a total of 20 mA and measures 4.5" x 5.0" x 2.4" overall. This synthesizer will interface directly to the Drake TR33C and to the Heathkit HT with minor modification.

The one I built fits right on the top of my TR33C with Velcro holding it in place. It is connected to the rig by a single length of RG-174/U cable, using the auxiliary jack on the back of the radio. The unit goes on and off with the TR33C, so there is no need for a separate ON/OFF switch on the synthesizer.

Schematics

Fig. 1 shows a block diagram of the PLL synthesizer. This diagram shows the frequencies for 144-148 MHz, although these are not the limits of coverage. The diagram in Fig. 1 illustrates that the input frequency to the system is the reference signal. It is one input to the phase comparator. The other input to the phase comparator is the i-f ÷N, which varies directly with the VCO since the LO and N are constant. The phase comparator outputs a correction signal that is applied to the VCO through a low pass filter. The digital edge triggered-phase comparator used here will maintain inputs of both frequency and phase coherence at lock. Thus, the lock range is the capture range, and locking on harmonics is not possible.

Fig. 2 is a complete schematic of the PLL frequency synthesizer. Also shown are TR33C and Heathkit HT interface modifications. Synthesizer power must be regulated. The power supply is a 723 precision regulator. The 723 is wired with no external components. Consequently, the chip reference voltage of about 7.15 volts becomes the output voltage for the synthesizer. The 723 offers high ripple and noise rejection. Three terminal regulator substitutes are not recommended if any mobile operation is planned where alternator whine may become a problem.

The VCO is a grounded base Colpitts oscillator. It offers high stability and separate outputs for the rig and mixer buffers. L1, C1, and the varactor diode comprise the tuned circuit. C1 may be made variable to adjust the VCO center frequency and L1 fixed. Both L1 and C1 can be made variable so that both the spread

(L1) and center frequency (C1) of the VCO are adjustable. However, such control is not necessary. The rig buffer is a broadband amplifier. The load inductance is taped to match the cable going to the radio.

The VCO-to-mixer buffer is a single CMOS quad NAND gate chip. Each gate is wired as an inverter and is biased up for linear operation. This buffer configuration offers the following advantages: excellent reverse isolation from the mixer, four stages, low current draw, high input impedance, and few parts count. The mixer is a dual gate MOSFET with a resistive load. The dual gate MOSFET offers good isolation between the VCO and LO signals. However, drive to this stage should be the minimum required at each input to reduce crosstalk as much as possible. Following the mixer is an i-f amplifier. A grounded emitter circuit is used to achieve the high gain required to produce a CMOS compatible square wave i-f output. The reference oscillator and divider are obtained using a single CD4060 RCA CMOS chip. This reduces component count and simplifies wiring, although it may increase the cost a little.

The local oscillator employs a JFET for high stability and low current operation. As can be seen, the LO has a switchable capacitor to shift its frequency slightly. This is how the 5 kHz steps are implemented.

The divide-by-N and phase comparator are combined on one Hughes CMOS chip. The phase comparator is of the digital edge triggered type, so the duty cycles of the incoming signals are not important. The divide-by-N portion accepts three BCD and one 7 bit binary number, which are added together to form the final division integer. The binary inputs may be used to generate offset splits between transmit and receive, but only the BCD

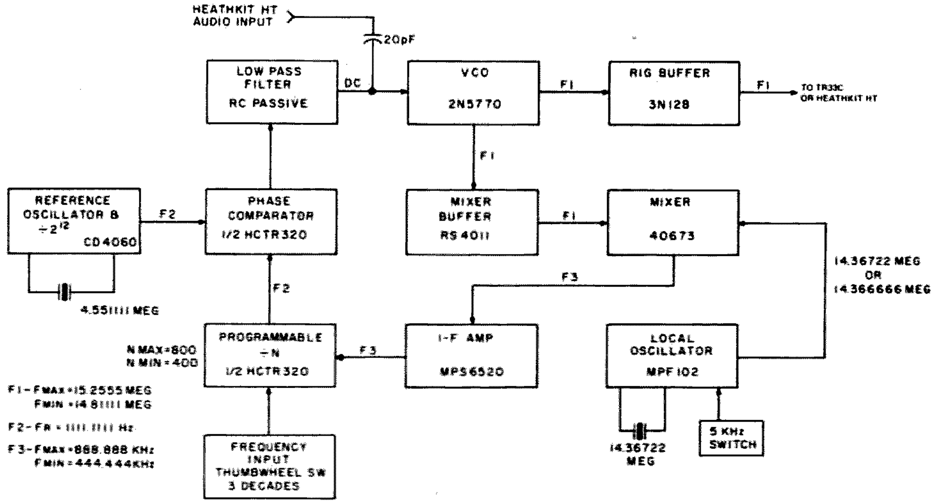

Fig. 1. Block diagram of the PLL 2m synthesizer showing the frequencies for 144-148 MHz coverage with TR33C.

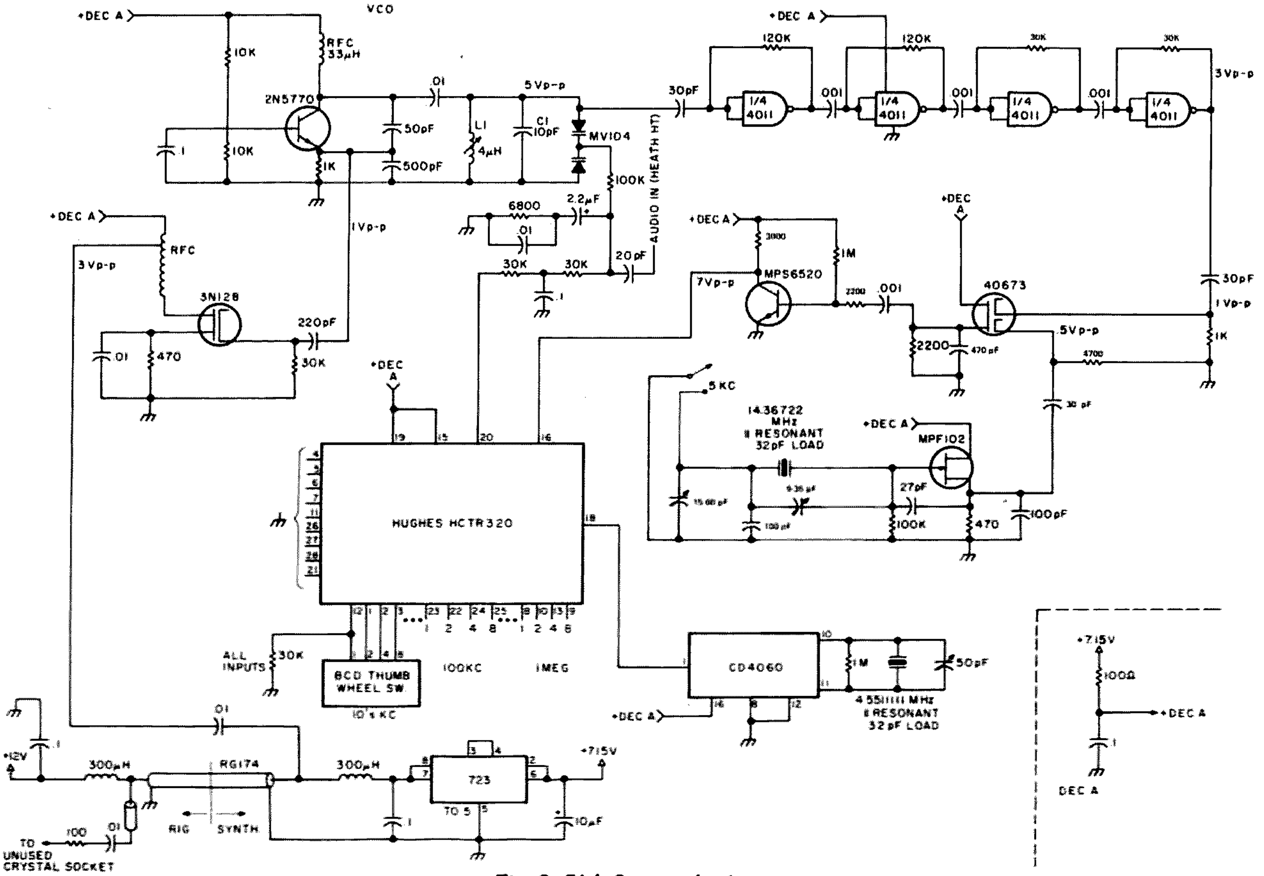

Fig. 2. PLL 2m synthesizer.

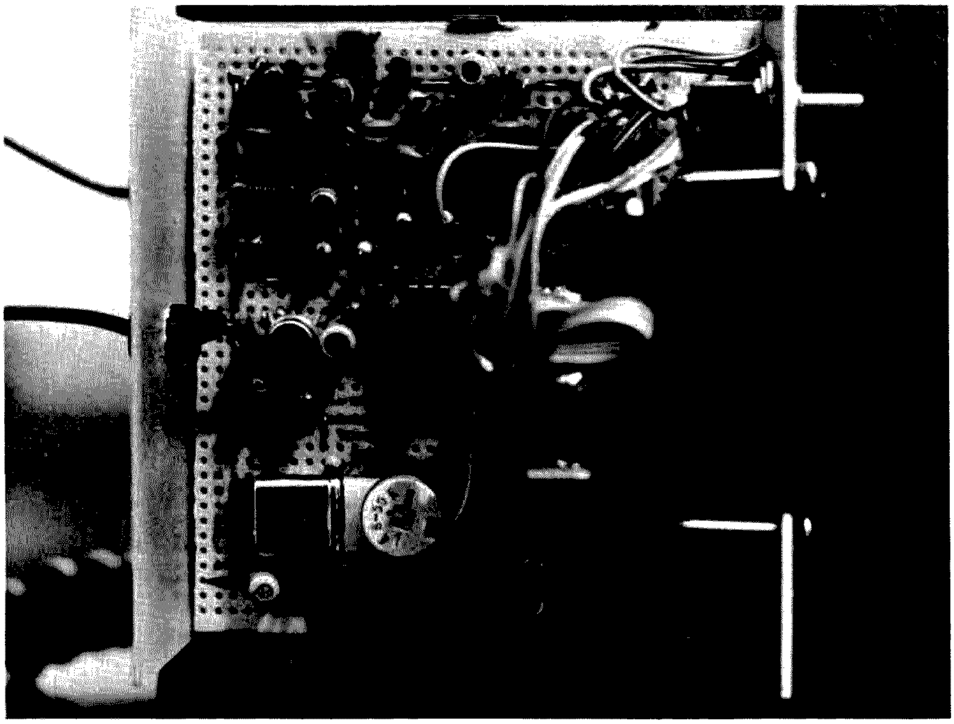

Top view of the synthesizer. Reference oscillator is located in the lower left portion of the perfboard.

inputs are used here and the binary inputs are all tied to ground. Also employed on the chip is a Schmitt trigger input for the i-f. The output of the phase comparator is filtered by the passive low pass filter and applied as input to the VCO in order to maintain lock.

Construction Tips

Either single or multiple board construction of the PLL synthesizer is possible. I used a single board approach employing the IC breadboard available from Radio Shack (#276-154). If a single board is used, then the component layout must be carefully planned. I put the VCO and LO on opposite corners of the board to help isolate them from one another. Fig. 3 illustrates the stage layout used. Before soldering the components in place, I arranged them for shortest lead length and fewest required jumpers. All stages must be either RC or LC decoupled from the supply line. RC decoupling is effective and less expensive then LC decoupling. The importance of having a sufficient ground plane cannot be overstated. If the Radio Shack breadboard is used, the ground plane must be provided after the PLL is operational. This is accomplished by cutting a piece of single-sided, copperclad, prepunched board to the same dimensions as the breadboard. Then ground leads are soldered at every stage on the breadboard to protrude from the copper foil side. These bare wires are then aligned with their corresponding holes on the copperclad perfboard. The two boards are sandwiched together and the numerous ground leads soldered to the perfboard ground plane as shown in Fig. 4. Also, hobby store "solderable tin" may be used to make stand-up shields between the rf stages.

If a multiple board arrangement is used, then the LO and reference oscillator should share their own circuit board as proposed in Fig. 6. The VCO and its buffers also comprise a sensible board. A preferable method would be to install the VCO and its buffers in a shielded box if space permits. In any configuration, the VCO components should be glued in place and its circuit board acoustically decoupled to minimize microphonics. Double-sided foam tape works well for this purpose. Braided strap should be used to make interboard ground connections. This strap is called slot car pickup cable in hobby stores.

Toroids are preferable to tubular inductors, and their use is encouraged if possible. This will help make the circuit less susceptible to nearby rf fields.

Alternative Stages

Every stage has a suitable alternative. The rf section works quite well, so I won't recommend any changes there. However, you may wish to substitute different transistors for the VCO, i-f amp, LO, or rig buffer. For the VCO you want a transistor with a low output capacitance and medium gain. The i-f amp should have a garden variety high gain device with low leakage current. Almost any JFET will work for the LO with the appropriate biasing. A JFET may also be substituted directly for the MOSFET shown as the rig buffer with little difficulty.

The Hughes HCTR320 synthesizer chip was selected to conserve board space, to reduce component count, and to simplify wiring. However, if board space is not a problem for you, or if you have difficulty obtaining this chip, it may be replaced by two readily available chips as shown in Fig. 5. The

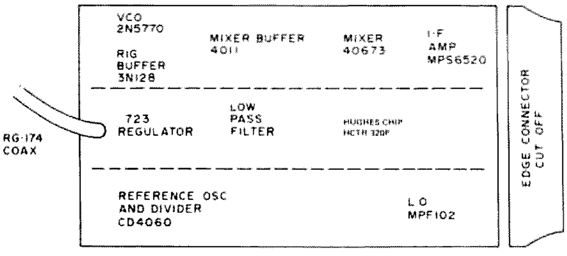

Fig. 3. Single board synthesizer layout using Radio Shack breadboard and Hughes synthesizer chip.

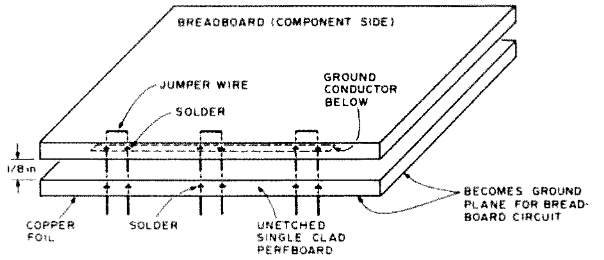

Fig. 4. Method for supplying a ground to breadboard circuits.

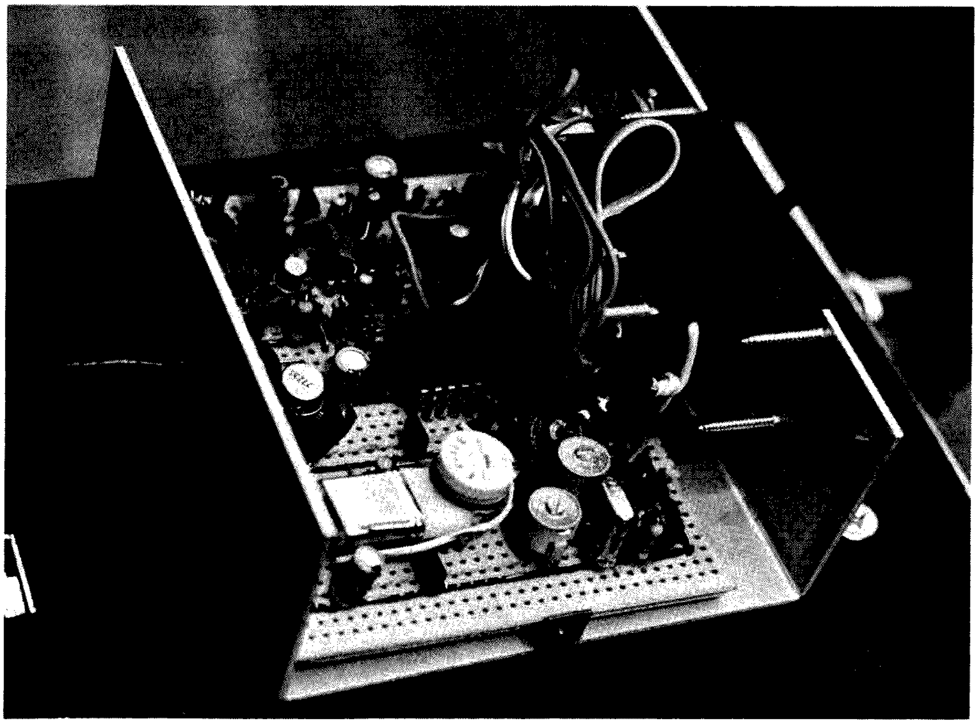
divide-by-N function is now handled by the RCA CD4059 programmable divider, and the phase comparator is obtained using two type D CMOS flip-flops. Alternatively, the phase comparator number two on the CD4046 phase locked loop chip may also be substituted for the digital edge triggered type called for above. It should be noted that, if the Hughes chip is eliminated, an additional stage of i-f amp may be required to properly condition the i-f signal for the CD4059 counter.

Troubleshooting

Not much difficulty is anticipated in getting the PLL operational. If something is amiss, start with the VCO. Verify the output amplitude and frequency as well as range of the VCO. Make sure that you have not forgotten the 100k Ohm resistor between the loop filter and the VCO. Check the signal levels at the mixer inputs. Verify that the local oscillator is working properly. Once the mixer is operational, check the i-f amp for a high amplitude clean output. Check the output of the divide-by-N chip to see if the chip is responding to the i-f signal. If it is not, then adjust the i-f amp components until an acceptable signal is presented to the divide-by-N chip. On the Hughes chip, pin 14 is the divide-by-N output. Once the appropriate signal is appearing at the output of the divide-by-N logic, check to make sure the reference oscillator is working and the divider is generating the required reference frequency. Verify the inputs to the divide-by-N chip and make sure none of the CMOS inputs are floating. Look at the output of the phase comparator with a dc coupled oscilloscope. If the output is saturated, go back to the rf section and start with the VCO to look for the problem. If the output is oscillatory, then you probably just need an adjustment of the low pass filter. Try changing the damping resistor and/or integrating capacitor in an effort to stop the loop from oscillating. If this fails, seek references on phase locked loop low pass filters in the library. The Signetics analog manual has a thorough discussion of the loop filter used here.



Another view of the 2m synthesizer. The complete circuit is assembled using point-to-point breadboard techniques.

Interfacing

The synthesizer will work without modification for the TR33C. This ham uses the Drake Mike Encoder to achieve touchtone capability, which frees the mini jack on the rear panel for synthesizer application. As shown in Fig. 2, the dc supply to the synthesizer goes through the center conductor of a length of RG-174/U coax. In return, the synthesizer sends its rf output back down the same wire and connectors. Thus, there is no inconvenience associated with this synthesizer. The dc supply and rf are isolated by rf chokes at each end, and the rf is coupled by capacitors at both ends. The rf goes to an unused crystal socket in the rig. The dc supply comes from the 12 volt switched line in the radio, so there is no need for an ON/OFF switch on the synthesizer.

The same system used with the TR33C may also be used for the Heathkit HT. However, the TR33C applies the audio modulation to the 10.7 MHz transmit mix-up oscillator so the synthesizer need not be interfaced with audio signals. In the case of the Heathkit HT, audio will have to be applied to the VCO in order to accomplish frequency modulation. This

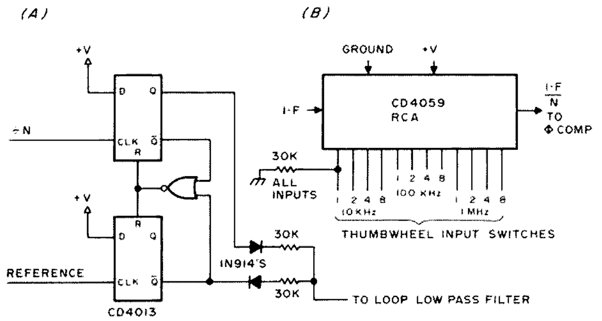


Fig. 5. Alternative digital logic for the PLL synthesizer. a) Phase comparator (CMOS); b) ÷N (CMOS).

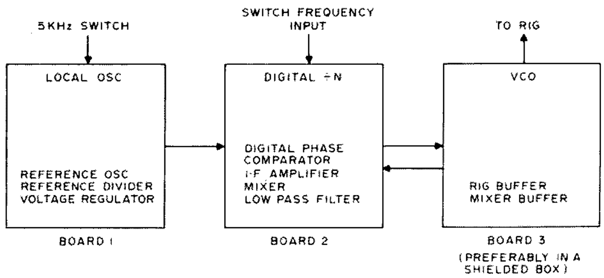

Fig. 6. Suggested multiple board synthesizer.

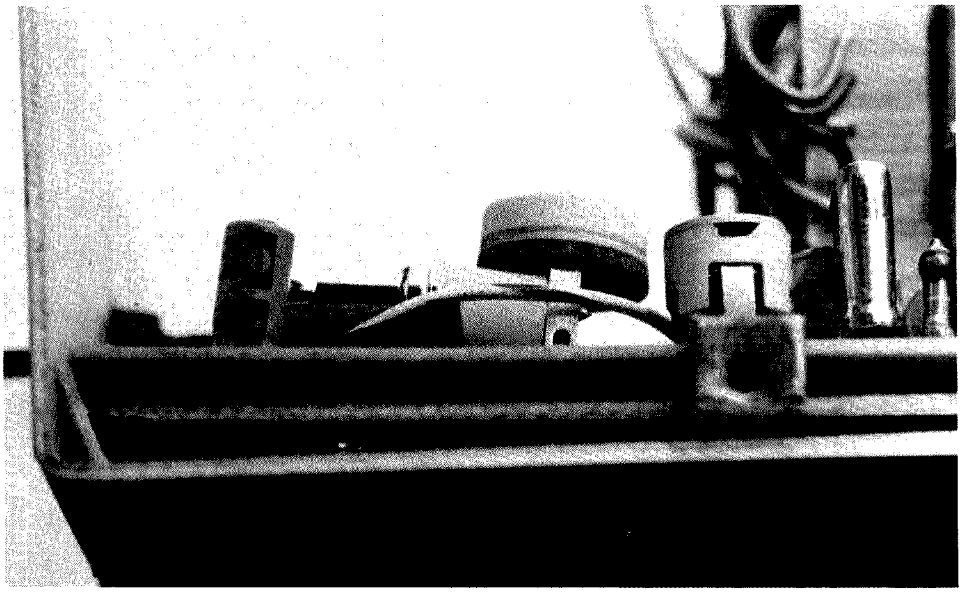

Close-up of the mounting bracket employed to secure the two perfboards. Oscillator components are visible above the bracket.

connection is shown in Fig. 2.

Of course, the basic synthesizer will work with any radio if the appropriate changes are made. Primarily, these changes involve the mathematics of the phase locked loop relative to the desired application. Tutorial information regarding the design of phase locked loops is available from RCA and Motorola upon request. Some sources are listed as references below. It should be pointed out that spurious responses in the synthesizer may result due to undesired interstage coupling or ground loops. The synthesizer described above offers inherent immunity to this problem. However, extreme layout or ground plane deficiencies can promote spurious interactions in any multifrequency system. It is your responsibility, as a ham, to check for and eliminate any spurious responses in your home brew synthesizer. Therefore, multiple board construction is recommended but is not necessary for the experienced rf home brewer.

A Keyboard Entry System For Your PLL Synthesizer

Here is a CMOS circuit that enables you to have keyboard frequency entry for your 2m synthesizer. It draws only 0.4 mA, has 4.5 digit LCD readout, and a built-in scanner capability. This is a viable alternative to thumbwheel or lever switch frequency input.

The circuit is shown in Fig. 7. It uses a Hamlin 3909 reflective LCD readout available through most Resco stores on order. RCA

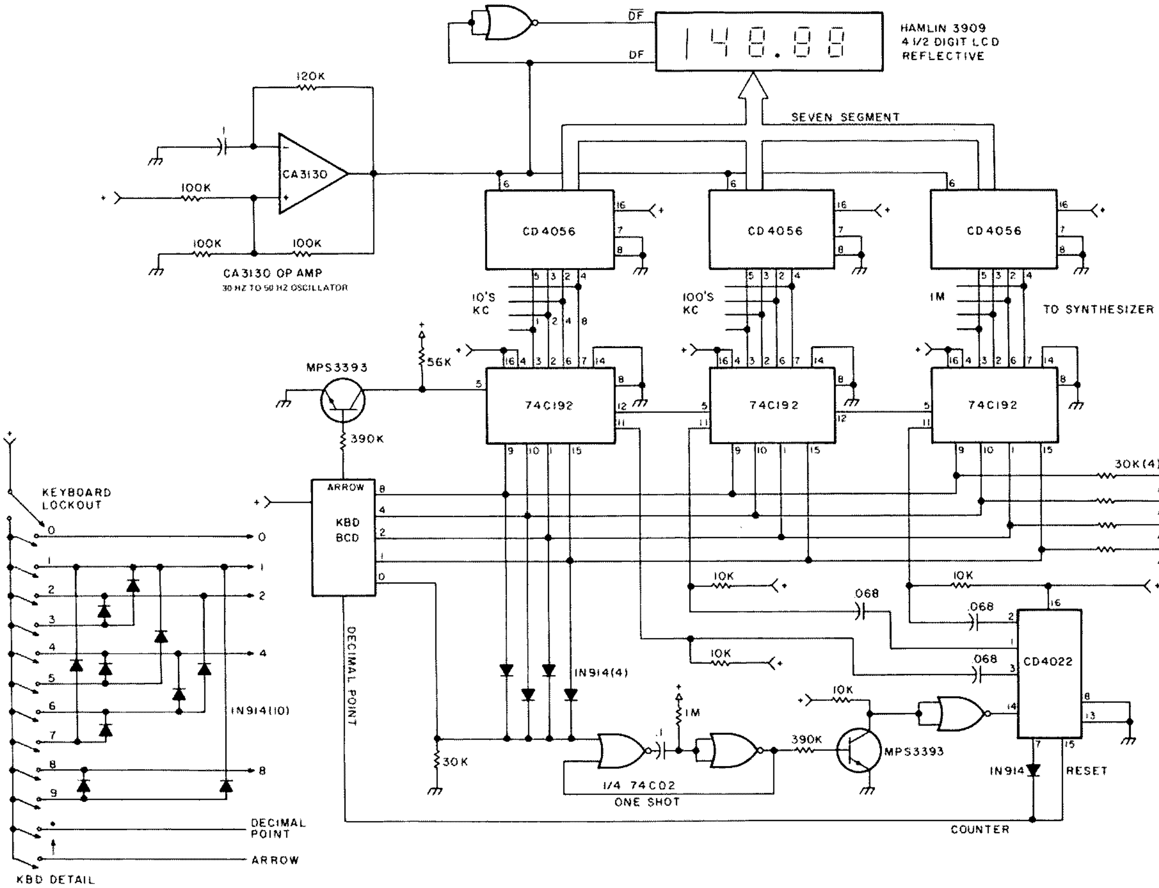

Fig. 7. Keyboard entry system.

CD4056 LCD drivers are also employed. The drivers and display may be replaced by a conventional LED arrangement in the interest of reduced overall cost, if current draw and portability are not important to you. The LCD readout is quite attractive, though, and is of the latest — black on white — FET LCD variety. The numerals are large and clearly visible in bright sunlight.

When a key is depressed, the one shot fires, causing the CD4022 counter to increment. Meanwhile the keyswitch places the appropriate BCD data on the input lines of the 74C192 presettable decade counters. By now, the falling edge of the previous output of the CD4022 causes the load line of one of the 74C192s to become active, thus loading the data into that counter. The load line is restored to an inactive high state before the data is removed from the input lines. The data is then removed after releasing the keyboard switch. The one shot cycles for the next entry. Inadvertent double entries are almost impossible due to the one shot. The cheapest noisiest keyboard switches may be used due to the adjustable duration of the flash picture the 74C192s take of the data lines.

Output from the presettable counters goes to the synthesizer input and to the display decoder-driver. Note that pull down resistors at the inputs of the programmable divide-by-N chip are not required if this encoder is employed, but are required if thumbwheel or lever switches are used. A keyboard lockout switch may be included if the keyboard is located where it is susceptible to accidental entries. ■

Buying Surplus

-- how to remain sane

Is inflation getting you down? Tired of fighting the high cost of living? Prices are rising everywhere — in the metropolitan area the inflation factor hovers between 10 and 15 percent. Maybe you are thinking of taking up stamp collecting or some less expensive hobby? Don't give up. Help is on the way!

If you are a builder of ham gear, or even if you do a little experimenting, you may be pleasantly surprised to learn that many of your supplies and electronic components can be purchased at discount prices. How? Simply by buying at surplus. Some of these prices taken from a recent catalog may seem high to you: type 1625 tube, $11.25; dc meters, from $15 to $20; relays, $5 to $6. But did you know that these same components can be purchased as new merchandise from surplus sources at prices of $1.25, $3 to $4, and $1 to $2, respectively?

Let me point out that the situation is not all peaches and cream. There are certain factors in the surplus market which should be understood in order to reap the greatest benefit. The most prominent difference in the surplus market lies in the fact that it is not a substitute for the regular electronics dealer who generally offers for sale whatever you may wish to purchase. The surplus dealer is a seller of what he has to offer. Once you have grasped this fundamental difference, you've bridged the gap. If you can utilize some of the merchandise offered by the surplus dealer, tremendous savings are possible.

This proposition suggests a certain flexibility of mind. If a certain component is needed, the chances are good that it can be bought at surplus, but if you insist upon a part made to certain specification, perhaps made only by one manufacturer, then the odds are that you will not see it offered for sale in the surplus market. Also, one should try to put himself in the surplus dealer's shoes, so to speak. To my way of thinking, the surplus shops are roughly akin to the thrift stores presently being patronized by knowledgeable women ... if you can use what's available, substantial economies are possible.

How do you pick a good surplus dealer? If you are located near a large city, why not drop in and see for yourself? If this is not convenient, you can ask for the various catalogs that are available. I have noticed that many of the better surplus houses generally have a supply of such catalogs. In some cases, you may be asked to pay for the cost of mailing the catalog.

With the catalog in hand, you are in a much better position to see for yourself the size, shape and style of what is being offered for sale. Often this helps to clear up any doubtful points that might exist. If you can't find what you need in catalog A, there are others that may carry the wanted item. Sometimes a catalog may offer merchandise in groups of several pieces, all at bargain prices. This economy allows you to buy at the lowest possible cost and still have something left over for the spare parts box. Over the years, I have amassed a fair sized collection of catalogs from various surplus dealers. While I do not believe in favorites, a few outfits have served me without headache or heartache for more years than I care to recall, among them Meshna and Fair Radio. Naturally, there are many other respectable firms dealing in surplus.

Finally, if you should experience any trouble, real or otherwise, in your business dealing with any surplus firm, my advice is quite simple: Holler, loud and clear. Amazingly simple and effective, that formula!

When you order from any mail-order house, it is always wise to state in big, bold letters: No substitutes/no back orders/no credit slips/refund any overage in check or stamps.

Good surplusing! ■

How To Buy Surplus Parts

-- pick a good supplier

Sooner or later even the most dedicated parts scrounger must buy parts for his projects. Some people build equipment using the latest, state-of-the-art semiconductors and parts. They have no choice; they must buy all of their parts, and usually from an industrial supplier at that! But if you are like most people, you fit somewhere in between these extremes. Most projects send you to both the junk box and the local electronics store.

The problem is that you may not be able to get what you want, or you pay too much or too little and don't realize it. Purchasing electronic parts (or anything else for that matter) is an art unto itself. If you pride yourself on quality projects at lowest prices, you'll want to learn more about electronic purchasing. To my knowledge (dating over 10 years), no one has published a good general article on electronic parts buying. Hopefully, this article will be the first!

Actually, this article was prompted by one thing. Readers interested in building some of the construction projects I have published have written to ask how to get certain parts. After reading some of the letters, it dawned on me that not everyone has good sources of supply and that I should write about how to go about getting parts. I might add, at this point, that the techniques I write about were developed during about 10 years at the school of hard knocks. So my methods are based on experience. If there are any professional buyers reading this, I apologize for some of my rather unusual methods!

Before getting into specifics, there are a few things you should do to make your purchasing easier. It is important that you have good suppliers. If you don't, you can waste both time and money running around for your parts. By good I mean suppliers who usually carry the items you need and can be trusted to help when your purchases aren't what you want or are defective. When you find you have a good electronic supplier, be nice to him. And dump the bad ones in a hurry. Here's how to go about choosing your suppliers.

Picking out a good electronic supplier is a job like selecting a reputable car dealer. You first locate him, size him up, and then perhaps buy a car from him. Later you may have some after-sale servicing done, and so on. So it is with the electronics dealer. You want to find him first. Get out the phone book for your area and look under "Electronics." Jot down on a piece of paper the names and addresses of any listings. You are only concerned with *retail* distributors at this point, if you are an individual. Wholesale distributors and some manufacturers may show you the door if you don't have a resale number. (A resale number is a number issued to you by the State Franchise Tax Board. It allows you to buy goods without paying state sales tax. However, you must resell the goods and have the customer pay the tax, or keep the goods and you must pay.) While collecting the names and addresses of distributors, check the phone book of any large city you happen to live by for more prospects. If you happen to live in a rural area, like I once did, give the phone book a glance and then refer to the various mail-order ads in this (and other) magazines.

The next step is to find out what sort of people the dealers you found are and what kind of parts they carry. You may be tempted to skip this part, but don't! You want to know more about your suppliers in order to make better buys. Suppose one dealer had some 7490 ICs for $1.69 each, and another had the same thing for 5 for a dollar. Chances are that if you want that IC, you would walk into the $1.69 place first (revised Murphy's Law). If you were aware of the second dealer, you could have gotten not only that 7490, but 4 others for future projects and paid only a dollar at that! And that is the way it often is in electronics.

In your spare time, pay the dealers nearest to your home a visit. You don't have to be building anything to call on them. While you are there, take mental notes on the stock available and how useful it is to you. For example, you like to work with ICs. Does the distributor have

many different kinds of ICs? How about resistors, caps, cabinets, etc? You might want to jot down next to the dealer's name on your list some of the things he has in quantity or has low prices on. You might also note whether he has surplus or new stock – surplus electronics can be real money-savers! When you have either the time or the opportunity, drop by the distributors farther from your home. There's no sense in ignoring anyone simply because they are a distance from your house. And with the larger outfits, a telephone call will bring your order to your door COD. But check with your distributor before you try a COD; not all firms are set up for it.

After you have made up your list of dealers with addresses, phone numbers, and hopefully any comments about their stock, keep it in a safe place until needed.

When you are ready to start a project, locate as many parts as you can from your junk box or from generous friends. Then dig out that list of dealers and scan it for prospects. Either visit or call those dealers who might have your parts. Check to see how much they are and if they are readily available. If you are in a hurry (say you are putting up a tower and need extra coax), you will have to buy from the distributor who has the parts in stock. But if you were foresighted enough to plan ahead and have more time to shop, you can save by trying at least one other store for your parts (preferably two others). Be careful of the dealer who says he can have it for you in a week. If you know he keeps his promises, fine; if not, try somewhere else if your time is limited. Electronic parts are notoriously hard to get on schedule, even for the best of dealers.

Here are some tips for buying parts: Concentrate on the most expensive parts when you shop. Then worry about the cheaper ones. It's easy to sweat over a few resistors and then blow dollars on a cabinet without a second thought. Note that some parts tend to have the same prices all over your area. Nationally known brands of tubes and semiconductor universal replacements are good examples, and it doesn't matter too much where you buy them. Availability will probably mean more to you at this point.

Don't be afraid to use several distributors for all your purchases; this is normal more often than not. Recently I built a synthesized commercial AM/FM tuner. It cost $100 in parts, which I ordered from 2 local stores, 4 mail-order houses, and one industrial supplier. And, in addition, I received a part sample from a major IC house, free. So this is what a big order can come to! I ordered this way, because the mail-order houses had the ICs cheaper, the industrial distributor had the state-of-the-art type parts unavailable elsewhere, and the locals happened to have the various odds and ends. I saved about $35.00.

So you build your project, confident you bought good parts and saved money. If it works, congratulations! If not, and you trace the problem to a bad part, you really get to check out your dealer! Actually, this tests you as well as the dealer, because your attitude can influence whether you get your part exchanged or not. That's just human nature. I have seen too many people vent their spleen on a salesman, who then gets mad and gives the customer the most shopworn part in stock. If you are reasonable, you are far more likely to get a replacement part and perhaps a cup of coffee and a little advice. Try it! Then too, you get to see how a dealer performs. If he replaces it, fine. If not, or if he sends you to another place of business, or tries to sell you a replacement at a discount price, look out! I am rather wary of outfits like these, personally. I also don't care for those who have signs all over proclaiming, "No return or refund." Why? The manufacturers of electronic parts (especially semiconductors and tubes) will replace bad parts from a distributor free.

Now that I have discussed the basics of buying from the local dealer/distributor, let's go on to some special cases. Take the mail-order house, for instance. I believe that mail-order suppliers are popular because they offer parts at low prices that are often hard to get. Here's how to deal with them.

Dealing with most mail-order houses is easy. But there are a few things you can do to get better service. The first thing you do is make up a parts shopping list. Then look in the back of *73* for names and prices. Also, it would be wise to pick up copies of *Popular Electronics* and *Radio Electronics* magazines for other names. Not all mail-order houses advertise in more than one magazine. And sometimes you can get better prices from another mail-order house. Be careful of very low prices on certain parts. This usually means either the supplier made a large purchase (which he would shout about) or is selling junk. Junk is just what the name implies, and you often get what you pay for. You should be aware that junk ICs, for instance, are parts rejected by the IC manufacturer for various reasons, and then barreled and sold to the highest bidder. The buyer (dealer/mail-order house, etc.) tests them, puts a part number on them, and sells them dirt cheap. You can tell because these parts don't have the manufacturer's name on them – just the part number written on in pencil or stamped on. I strongly advise you not to use them;

Rediform
1H 140

ORIGINAL

Fig. 1.

the money you save will be made up in lost time troubleshooting later. Compare ads and look for the best prices. Then order.

A good way to deal with a mail-order house is to write a purchase order. See Fig. 1. You can get these forms from your local stationery store. Just ask for Rediform 1H140. Fill out the form with the parts you want and then the total prices. Make sure that you specify what package you want your ICs to come in ("14 pin DIP" or "TO-5 can" are OK) and that you include shipping costs. Note that some outfits ship small items postpaid. Also, some have handling charges. Total up the cost, and enter it at the bottom of the page. Then make out a check or money order for the amount. Never send cash; it may not reach its destination. Then write in your address and the company you are buying from. For best results, print in large numbers and letters. If you bought the Rediform I suggested, you will have a duplicate of the PO you just wrote. Keep it until your parts arrive, and then check them off the list as they are unpacked. You might also hang on to the PO and the canceled checks for tax purposes if you are in business. Why write a PO? Many businesses in mail-order do not send an invoice telling what you bought. This way you have a record that will serve as a reminder, ending the "Did I get what I ordered?" blues.

The best way to see how good a mail-order house is is to send them a small order (say $10 or so). This is the way I evaluate a new firm. I get to see how fast they handle it, the quality of their parts, and how they react to returns if I don't like their merchandise. I might add that I have dealt with essentially all of the people advertising in this magazine over the years, and I have found only one house that was suspicious in its dealings. They aren't around anymore. You will find houses that have excellent service but lousy parts, and vice versa. A few offer excellent parts and service, and if you do much buying by mail-order, you'll quickly find out who they are.

The next and last step up the ladder is the industrial electronics distributor. In the old days you would think Allied and Newark, but today you call on other firms. Dealing with an industrial distributor involves a certain ritual, and you must be able to meet their minimum order requirements. In the Los Angeles area, for example, Hamilton Electro Sales has a minimum order of $5.00 or more. Cramer Electronics has a $25.00 minimum. It would be wise for you to either pool orders for several projects or get several interested friends together for one order to make the minimum order and get better service.

The first step is to locate those outfits near your home. If you did your homework with the phone book, you may have some good leads. Generally, these outfits are located in major cities like New York, Chicago, Los Angeles, etc., so look there.

Once you have found some candidates, call them up and ask for the sales desk. Then ask the person who answers for either a catalog (Cramer has a good one) or a *line card*, and have it sent to you. Caution: If you are an individual, you may not get one. In fact, the salesperson may put you on hold for a half hour or hang up! If so, drop them fast and try another supplier. This treatment usually suggests what you'll get on your first order: the famous cold shoulder.

The ritual for ordering from an industrial distributor goes something like this: You call to get the current prices on your parts and find out whether they are in stock. With most outfits, you are talking to a person sitting at a computer terminal, and that means you must give him the exact part number and the manufacturer of the part. The manufacturer must be one on the industrial distributor's line card, a notebook-size piece of paper listing the manufacturers the distributor represents. If you can't cross-reference your parts over to a manufacturer he carries, you are out of luck. You must be able to tell him exactly what you want, or the salesman may not be able to help you. Ask for a "741", and he'll be puzzled. But ask for an "MC-1741P by Motorola" and you'll get results.

After you give the salesman the part and manufacturer, he'll ask for the quantity you need. Tell him. He'll check the terminal and give you the price of each and whether they are in stock.

At this point, there are three things you can do. Have the parts sent COD, have them sent and billed on your account, or mail an order and pay cash. Also, some outfits will accept your order and put it on "will call" for you. The first method is preferred for dealing with large parts houses. If you have the order sent COD, you get it sooner, and the extra cost is small. Also, there is less chance that a foul-up in the distributor's credit department will reach you. This approach is highly recommended if you are ordering as an individual. The second method is for business people only – you hold an account with the industrial distributor, and you are billed monthly. This method can work well if the credit bureaucracy is well organized. But, in my area, this isn't always the case. Recently I had to scream at the president of a large outfit and knock heads in the credit department over a simple computer error. Yes, I am well acquainted with credit problems. The third method works if you do it a certain way – call and casually inquire if your parts are available. If so, fine. Do not let the salesman talk you into placing an order! Instead, write up a purchase order and send it to that salesman. Enclose your check for the parts and any sales tax. You do not have to allow for postage; most outfits include it in their parts cost. If you send extra money for postage, they will pocket it. Keep your money. If they want postage, let them bill you. This method works well for cash customers, and it keeps the credit department out of the act. If you like, try "will call" service if offered. This is the quickest way of getting your parts if you are located close to the distributor.

There is a chance that you will get the wrong parts or get defective units. Industrial distributors usually require that you call their customer service department and get a *R*eturn *M*aterial *A*uthorization (RMA) number before returning the parts. You *must* return your parts with this number! Otherwise, your return will be (ulp!) ... returned! Without any action. Don't forget the RMA number. Also, be sure to enclose a note with your name/address, the sales order number (or your PO number), and the nature of the problem.

That's the gist of dealing with a commercial distributor. This may sound like a lot of bother to you for just a few parts, but you must go to a distributor like this if you are using either hard-to-get parts or state-of-the-art components.

Now that you know a little more about buying electronic parts, which places are the best for buying your parts? That's pretty simple. Are you in a hurry for your stuff? Buy from your local dealer/distributor or industrial disbributor. Use "will call," and pick them up yourself. Want to save some money? Use a local surplus dealer or mail-order houses. Need state-of-the-art or hard-to-get parts? Use an industrial distributor. If you are like me, you will probably end up using all three sources for a project. Good luck! ■

Social Events

BOSTON MA
AUG 25-27

Computermania, an exhibition of the new hobby computers, will be held on August 25, 26, and 27, 1977, at the Boston Commonwealth Pier. On exhibit will be hundreds of computers, memory boards, printers, floppy disks, new calculators, new TV games, demonstrations, forums, talks, and prizes. Over 250 exhibits. For info, write Computermania, Peterborough NH 03458, or call Toll Free (800) 258-5473.

ROLLAG MN
SEPT 2-5

The Western Minnesota Steam Threshers reunion will be held in Rollag, Minnesota, Sept. 2-5, 1977. Featured will be amateur special events station WMØSTR. Plans are being made for operation of CW and SSB on 80 through 10 meters, and possibly on 6 meters. QSL certificate will be sent upon verification of the log and receipt of an SASE. Send to: WBØLRK, PO Box 596, Fertile MN 56540.

SAINT ANDREWS-BY-THE-SEA
NEW BRUNSWICK
SEPT 3-5

The All Saints Amateur Group will hold their Family-Holiday Hamfest on September 3rd, 4th, 5th, 1977, at the Algonquin Hotel in Saint Andrews-by-the-Sea, New Brunswick. The program includes: a technical forum, flea market, antique radio show, outstanding speakers, exhibit of leading ham equipment, prizes and awards, transmitter hunt, and much more. A full range of accommodations is available. For more information write: Hamfest 77, R.R. 325-8, Rothesay, New Brunswick, Canada E0G 2W0.

DANVILLE IL
SEPT 4

The Danville Hamfest will be held on Labor Day weekend, Sunday, September 4, 1977, at beautiful Douglas Park, one block from I-74 Bowman Ave. exit in Danville, Illinois. The Danville Hamfest is cosponsored by the Illiana Repeater System and the Vermilion County Amateur Radio Association. For more information write Don Russell, R5, Danville IL 61832.

CLEVELAND OH
SEPT 10

The Cleveland Hamfest Association presents the 1977 Cleveland Hamfest to be held on Saturday, September 10, 1977, from 6 am to 5 pm at the German Central Farms, 7863 York Road, Parma. Hamfest includes family picnic area, YL activities for the whole family, commercial displays of the very latest in ham gear. Door prizes throughout the day with final grand prize drawing at 1600. W8QV for mobile check-ins for number on 146.52 from 0600 to 1200 with mobile prize drawing at 1400. Early ticket donations are $1.50 before August 27th, $2.00 at gate for all over 12 years of age. Flea market parking $1.50 additional per space at 0600. For more information write Cleveland Hamfest Association, Box 43413, Cleveland OH 44143.

MELBOURNE FL
SEPT 10-11

The 12th Annual Melbourne Hamfest will be held Saturday and Sunday, September 10 and 11, 1977, from 9 am to 5 pm each day in the air conditioned Melbourne Civic Auditorium located on Hibiscus Boulevard. Donation is $2.50 per person. Full program includes forums, meetings, auction, swap tables, commercial exhibits, awards, prizes, etc. Contact K4HPT, 2749 Herford Road, Melbourne FL 32935 for swap table reservations. FCC exams on Saturday; donation not needed for exams. Form 610 must be filed with FCC, Room 919, 51 S.W. First Avenue, Miami FL 33130, not later than August 31, 1977. Hamfest talk-in on 25/85 and 52/52. Sponsored by Platinum Coast Amateur Radio Society. For more info write PO Box 1004, Melbourne FL 32901.

MENA AR
SEPT 10-11

The Queen Wilhelmina Hamfest will be held atop Rich Mountain on September 10 and 11, 1977. There will be door prizes, games, and exhibits for everyone. Talk-in on 3995 kHz, .52-.52, .19-.79. For more information contact Steven W. Myers WB5MFI, Rt. 1 Box 204, Hatfield AR 71945, (501) 389-6791.

FINDLAY OH
SEPT 11

The 35th Annual Findlay Hamfest will be held September 11 at the Riverside Park, Findlay, Ohio. Advance tickets are $1.50 and $2 at the gate. For tickets and additional information send an SASE to Clark Foltz W8UN, 122 W. Hobart, Findlay OH 45840.

FLINT MI
SEPT 11

The Greater Genesee Valley A.R.C. will hold a swap & shop on Sunday, September 11, 1977, from 8 am to 4 pm at the Southwestern High School in Flint, Michigan. Take I-69 to the Hammerberg Road exit located near downtown Flint. Tickets are $1.00 in advance, $1.50 at the door. Door prizes will be given away, and food sales available. Large tables will be available at reasonable price for sellers. No trunk sales. Talk-in on 31/91 and 52 simplex. For advance tickets, table reservation, and additional information contact Jack Walters WA8UXN, 1315 Butcher Road, Fenton MI 48430.

SOUTH DARTMOUTH MA
SEPT 11

The Semara Annual Picnic and Flea Market will be held on September 11 at the Stackhouse Street Fairgrounds, South Dartmouth, Massachusetts. Talk-in on 147.60-147.00.

HAMBURG NY
SEPT 17

The 6th Annual Hamburg International Hamfest 77 will be held September 17, 1977, at the Erie County Fairgrounds. Electronic flea market, amateur computer displays, manufacturers' displays, technical forums, women's programs, door prizes, etc. For additional information contact Fran Wilson 833-9631 or Bert Jones 873-3984.

HUDSONVILLE MI
SEPT 17

The Grand Rapids Amateur Radio Club will hold its annual Swap-N-Shop Saturday, September 17 from 8 am to 4 pm at the Hudsonville Fairgrounds in Hudsonville, Michigan, 12 miles southwest of Grand Rapids on M-21. Talk-in on 146.52 and 16/.76. $2 donation at the gate with plenty of refreshments and free tables available.

GRAYSLAKE IL
SEPT 17-18

Radio Expo '77 will be held September 17 and 18, 1977, at the Lake County Illinois Fairgrounds, Rts. 45 and 120, Grayslake, Illinois (halfway between Chicago and Milwaukee). Displays of the latest in electronic communications technical forums, gigantic flea market, thousands of dollars in door prizes, ladies' program, etc. Tickets $3 for both days, $2 in advance. Radio Expo Tickets, Box 1014, Arlington Heights IL 60006.

ROSS OH
SEPT 18

The Cincinnati Hamfest will be held at the *improved* Stricker's Grove, State Route No. 128, Ross (Venice), Ohio, on Sunday, September 18, 1977. Exhibits, contests, prizes, swaps, trades, thrilling and spectacular air show, group and net meetings, hidden transmitter hunt. Advance ticket $7.50 – at gate $8.00. Mail check or money order prior to September 11 to: Greater Cincinnati Amateur Radio Assn., c/o John P. Haungs WA8STX, Treasurer, 10615 Thornview Drive, Evendale OH 45241.

OAKWOOD GA
SEPT 18

Lanierland ARC will hold its fourth annual "Hamnic" at the Lanier Islands Dogwood Pavilion on September 18, 1977. Two large covered pavilions and large parking area for swap shop and exhibits. Food available. No entry fee for Hamnic; however, Lanier Islands charges $2.00 entry fee per car. Picnic, hiking, and swimming for the kids. First prize IC-22S. Many other prizes. Talk-in on W4IKR/4 on 3975 and .07/.67. For further information, write Terry Jones WB4FMJ, Route 1, Box 298, Oakwood, Georgia 30566.

MT. CLEMENS MI
SEPT 18

L'anse Creuse A.R.C. presents its 5th Annual Swap and Shop to be held on September 18, 1977, at L'anse Creuse High School, Mt. Clemens, Michigan, 0900-1500. Prizes, plenty of food and parking. Directions: I-94 eastbound, exit Metro Pkwy, Metro Pkwy to Crocker, left on Crocker to Reimold, right on Reimold to last school – L'anse Creuse High School. Admission: $1.50 at door, $1 in advance. SASE to WB8QFR, 32111 Harper Ave., St. Clair Shores MI 48082.

HARRISBURG PA
SEPT 18

The 4th Annual Electronic Swap Fest of the Central Pennsylvania Repeater Association will be held Sunday, September 18, 1977, at the Park and Shop Garage, 200 Block of Walnut Street, Center City, Harrisburg. Indoor parking for 1100 cars, so come rain or shine. Starts at 8 am. Registration $3.00. No charge for tailgating, wives or children. Talk-in on WA3KXG, 146.16/76, 146.52/52. For more information contact Roger Urben W3HUP, phone: (717) 761-7178.

PEORIA IL
SEPT 18

The Peoria Area Amateur Radio Club's 20th Annual Hamfest will be held Sunday, September 18, 1977 at the Exposition Gardens located on Northmoor Road just west of North University Avenue. Free coffee and donuts 8:30 to 9:00 am, free swapfest and free parking. Prizes will be given away. Advance tickets $1.50, door tickets $2.00. Talk-in on 146.94 simplex – call W9UVI. For hamfest tickets write Bruce Funston K9PWQ, 304 Indian Circle, East Peoria, IL 61611.

KENNER LA
SEPT 24-25

The Jefferson Amateur Radio Club and the Crescent City Computer Club would like to announce the New Orleans Hamfest/Computerfest which will be held at the Hilton Inn in Kenner LA (directly across from the New Orleans International Airport) on September 24 and 25. This is the ARRL Delta Division Convention for 1977 and is the largest ham outing in the deep south. This year's event will feature a banquet Saturday night with entertainment, two days of commercial exhibits, flea markets, forums, hospitality room, ladies' events, FCC examinations and more. Grand prize is a complete Drake "C-Line" ham

station. For more information contact the New Orleans Hamfest/Computerfest, PO Box 10111, Jefferson LA 70181.

MADISON WI
SEPT 25

The 5th Annual Madison Swapfest will be held Sunday, September 25 at Dane Co. Expo Center Youth Building, Madison WI. Rain or shine — inside facilities — doors open at 8 am. 12,000 sq. ft. of electronic equipment and components for hams, computer hobbyists and experimenters. Bring the whole family for delicious food and entertainment. Excellent overnite camping accommodations. Tickets — advanced $1.50; at door $2.00. Tables — advanced $2.00; at door $3.00. Make check or money order payable to M.A.R.A. — mail to M.A.R.A., Box 3403, Madison WI 53704. Reservations must be in by Sept. 10, 1977.

ERIE PA
SEPT 25

The 2nd Annual Erie HamJam will be held Sunday, September 25, 1977 at Rainbow Gardens, Waldameer Park. Door prizes, flea market, forums, large indoor facilities. For more information write Radio Assocation of Erie, Inc., PO Box 844, Erie PA 16512.

LOUISVILLE KY
SEPT 25

The Seventh Annual Greater Louisville Hamfest will be held on Sunday, September 25, 1977 at the Kentucky Fair and Exposition Center with marked exits off either I-65 or I-264. Indoor exhibitors area plus indoor or outdoor flea market areas. There will be meetings and forums, ladies' free bingo, also food and drinks available. Admission is $2 adults — 12 and under free. Flea market vendors pay admission price plus $2.00 per space indoor or $1.00 per space outdoor. For info contact Denny Schnurr K4GOU, 2415 Concord Dr., Louisville KY 40217, phone (502) 634-0619.

ADRIAN MI
SEPT 25

The Annual Adrian Hamfest will be held on Sunday, September 25, 1977 at the Lenawee County Fairgrounds, Adrian, Michigan. Prizes every hour! Grand prize drawing — 3 pm. Flea market and trunk sales. Tickets $1.50 advance, $2.00 at gate. Tables $2.50 half, $4.00 full. Talk-in on 31/91 and 52. For more information contact Adrian Amateur Radio Club, Box 26, Adrian, Michigan 49221, (517) 265-8016.

NEW BERLIN IL
SEPT 25

The Sangamon Valley Radio Club will hold its Second Annual Hamfest on Sunday, September 25, 1977 at the Sangamon County Fairgrounds, New Berlin, Illinois, 16 miles west of Springfield. Indoor display area and a covered pavilion. Food, refreshments, exhibits and ladies' activities. Overnite camping on grounds. Tickets $1 advance; $1.50 at gate. First prize — Wilson HT. Talk-in 146.28/.88 and .52. Info: Carole Churchill WB9QWR, 622 Magnolia, Rochester IL 62563.

WILLOW GROVE PA
OCT 1

The Mid-Atlantic States VHF Conference will be held on Saturday, October 1, 1977 at the Treadway Inn on Easton Road (Route 611, Exit 27 of the Pennsylvania Turnpike) in Willow Grove, Pennsylvania on the day before Hamarama 77 (at nearby Warrington, Pennsylvania). The conference will be an all day VHF program moderated by prominent VHFers. Advance registration is $2.50 (includes admission to Hamarama 77 on Sunday). Cocktail hour (cash bar) and get-together at 6:30 pm. Buffet dinner at 7:30 pm is $8.00. Special rates for rooms overnight. For advance registration contact Ron Whitsel WA3AXV, Chairman, PO Box 353, Southampton PA 18966, phone (215) 355-5730. Advance registration must be received by September 28, 1977. Indicate motel registration forms required.

MEMPHIS TN
OCT 1-2

The Memphis Hamfest, bigger and better than the 4,500 who attended last year, will be held at State Technical Institute, I-40 at Macon Road, on Saturday and Sunday, October 1 and 2. Demonstrations, displays, MARS meetings, flea market, ladies' flea market, too! Hospitality Room, informal dinners, XYL entertainment, many outstanding prizes. Dealers and distributors welcome. For further information contact Harry Simpson W4SCF, PO Box 27015, Memphis, Tennessee 38127.

WARRINGTON PA
OCT 2

The Mt. Airy VHF Radio Club (the Packrats) are holding "Hamarama 77" at the Bucks County Drive-In Theater, Route 611 (Easton Road), Warrington, Pennsylvania on Sunday, October 2, 1977, 8 am to 4 pm rain or shine. Registration $1.50, tailgating $2.00/space (bring your own table). Talk-in via W3CCX/3 on 52.525 and 146.52, WR3ACD on 222.98/224.58, WR3ADS on 147.63/147.03, and WR3AHC on 147.60/147.00. Advance registration to the Mid-Atlantic States VHF Conference includes admission to Hamarama. For information contact Ron Whitsel WA3AXV, Chairman, PO Box 353, Southampton PA 18966, phone (215) 355-5730.

CEDAR RAPIDS IA
OCT 2

The Cedar Valley Amateur Radio Club annual Hamfest will be held Sunday, October 2, 1977. Top prizes are Atlas 210X Xcvr, Wilson 1402 SM H/T, Heathkit HW-8 QRP CW Xcvr, Clegg FM-76 Xcvr, plus much more. Technical talks featuring Doug DeMaw W1FB. Manufacturers and dealers welcome. Talk-in on 146.16/.76, 146.52, 3.970, and 223.5 MHz. Advance tickets $1.50, $2.00 at the door. Write CVARC Hamfest, Box 994, Cedar Rapids IA 52406.

NEWPORT NH
OCT 2

Autumnfest, the first annual hamfest of the Connecticut Valley FM Association, will be held on October 2, 1977, at the Community Center, Belknap Ave., off Rt. 10, north end of the Common. Flea market opens at 9 am — auction at 2 pm. Program includes antenna gain contest, fox hunt on 52 simplex, frequency and modulation checks by W1RNZ, and talks and demonstrations throughout the day. Donation: $1.50 in advance — $2.00 at the door. Talk-in on 16/76 or on 52 simplex.

EAST RUTHERFORD NJ
OCT 8

The Knight Raiders VHF Club, K2DEL, presents its world famous Auction & Flea Market to be held at St. Joseph's Church of East Rutherford, New Jersey, Saturday, October 8, 1977 beginning at 10 am. Free admission — free parking. Flea market tables (in advance) $5 full table, $3 half table; (at door) $6 full table, $3.50 half table. Directions: take Rt. 17 north from Rt. 3 to East Rutherford, exit onto Paterson Plank Road, follow to traffic light with Diner on the corner, make sharp right, follow for one block, at light you will see St. Joseph's Church on your right, make right turn at corner and enter parking lot. For further information call: Bob Kovaleski (210) 473-7113, evenings only. Talk-in on 146.52. Send reservations and make checks payable to: Knight Raiders VHF Club Inc., PO Box 1054, Passaic NJ 07055 (reservations close October 1).

SHREWSBURY MA
OCT 8-9

The Heart Fund Hamboree (all proceeds to be given to the Heart Fund) will be held on October 8 and 9, 1977, at Simeon's Park on Route 9 in Shrewsbury MA. Program includes door prizes, trophies, special prizes and entertainment. For advance tickets send $1.50 donation (orders must be received by Sept. 15) — $2 donation at gate. Senior citizens and children 12 years or under free. For dealer space and ticket information write: Central Mass. 2-Way Radio Assoc., P.O. Box 154, Northboro MA 01532.

SYRACUSE NY
OCT 8

The Radio Amateurs of Greater Syracuse presents the Syracuse Hamfest, October 8, 1977 from 9 am to 5 pm at the Syracuse Auto Auction, Route 11, Nedrow, New York. Easy access from Route 81, 5 miles south of Syracuse. Food available all day at reasonable prices. Large exhibitor area and flea market under cover. Exhibitors: $13.00 (includes one 8-foot space, 8-foot table, two chairs and admission to hamfest). For further information: General info — RAGS Hamfest, Box 88, Liverpool NY 13088; exhibitors — Dale Mecomber WB2FJC, Box 87, Skaneateles Falls NY 13153.

YONKERS NY
OCT 9

The Yonkers Amateur Radio Club is holding "Super Hamfest 77" on October 9, 1977 (rain date Oct 16) from 9 am to 5 pm at Redmond Field, Cooke Avenue in Yonkers. Manufacturers displays, door prizes, raffles, refreshments and a general auction are all in store. Buyers $1, sellers $3 — bring your own table. Talk-in 146.265, 146.865, 146.52 simplex. For further information contact Doug McArtin WA2AUJ, 411 Bellevue Ave., Yonkers NY 10703, (914) 423-0515.

WINDSOR LOCKS CT
OCT 14-16

The Region 1 Air Force MARS Convention will be held on October 14, 15, 16, 1977 at the Howard Johnson's Conference Center, Center Street Exit 1-91, Windsor Locks, Connecticut. *73* publisher Wayne Green will be guest speaker.

SAN MATEO CA
OCT 15-16

The Greater Bay Area Hamfest and ARRL Pacific Division Convention will be a combined event this year held on Saturday and Sunday, October 15 and 16 at the Royal Coach Inn, centrally located on the San Francisco Peninsula just off the intersection of U.S. 101 and Route 92 in San Mateo. For more information contact the Greater Bay Area Hamfest, Box 751, San Mateo CA 94401.

TAYLOR MI
OCT 16

The Repeater Association of Downriver Amateur Radio (R.A.D.A.R.) Hamfest will be held on October 16, 1977, at the Kennedy High School located in Taylor, Michigan, on Northline Road, east of Telegraph (U.S. 24). Door prizes and food. Admission $2.00/YLs free. Reserved tables $1. Open 9 am until 3 pm. Talk-in will be on 52-52, 34-94, 93-33. For further info write: R.A.D.A.R. Inc., PO Box 1023, Southgate, Michigan 48195.

PLYMOUTH IN
OCT 30

The Radio and Electronics Swap and Shop, sponsored by the Marshall County Amateur Radio Club, will be held on Sunday, October 30, 1977, at the Plymouth, Indiana National Guard Armory, located at 1220 West Madison Street, from 8 am to 5 pm. Free tables, no charge for setup. Tickets $2 at door. Food, drink and door prizes. Talk-in on 146.07-67 and 146.52 simplex. For further information contact Wayne Zehner WA9INM, Rt. 3, Box 526, Plymouth IN 46563.

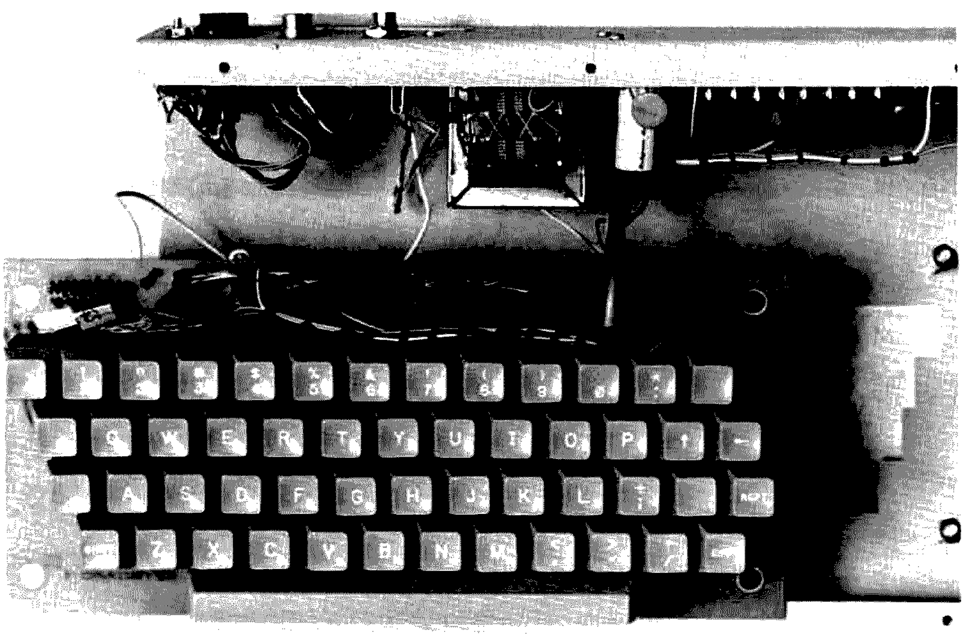
RTTY RKB-1 Revisited!

-- auto machine functions

About 15 ms after I started typing on my Model 15 teleprinter, I realized that this was not at all like typing on a modern electric typewriter. There simply had to be a better way. HAL's RKB-1 electronic keyboard was a step in the right direction. However, it still required the time-consuming and monotonous carriage return, carriage return, line feed, letters (CR, CR, LF, LTRS) procedure at the end of each line. This operation is used by all good RTTY aficionados to help ensure that the machine is set up properly to print the next line. This article describes a circuit that will, when actuated, cause the RKB-1 to perform the CR, CR, LF, LTRS operation automatically.

Photos by Anthony R. Donaldson



Toroids T0 through T6 can be seen above top row of keys.

Encoding the LTRS Character

The first modification requires the addition of a LTRS character. Encoding characters in the keyboard is performed by a toroid matrix. This matrix is composed of seven toroidal transformers labeled T0 through T6. The photo shows the T0 toroid located above the number 9 key. Toroid T6 is located above and between the number 2 and 3 keys. The remaining toroids are numbered consecutively in between. Toroids T0 through T4 are used to encode the standard five bit Baudot code. Toroids T5 and T6 are connected to a case-sense circuit. The purpose of this circuit is to send a LTRS or FIGS character automatically before the actual character depressed is sent, if necessary.

Fig. 1 shows how a LTRS character, represented by MMMMM in the Baudot code, can be encoded in the RKB-1. The character is encoded by connecting a thin enamel coated wire (approximately #30 AWG) to pin 20 of the keyswitch printed circuit board. This point is located directly above the number 0 key. It is a common tie point for about 30 other wires. The wire is then passed through the center of toroid T5. If you wish to actuate the LTRS character externally, the wire must be connected to an unused key. I found the key to the left of the A key to be convenient. Should you not wish to access the LTRS character, the wire is connected directly to pin 9 of the 7445 shown in Fig. 3. This single wire acts as the primary of each toroidal transformer. T0 through T4 are not used, since the Baudot code for the LTRS character does not contain any spaces. Only those characters requiring a space are fed through these toroids.

To further illustrate the technique, should you wish to add other characters, Fig. 2 shows another example. It indicates the proper connections to encode the FIGS character, MMSMM.

You should be aware of, but not necessarily concerned with, an anomaly in the keyboard. Since the toroid primary of each character passes through either the

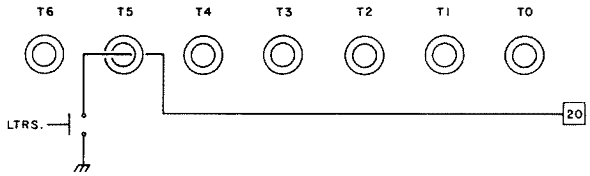


Fig. 1. LTRS encoding schematic.

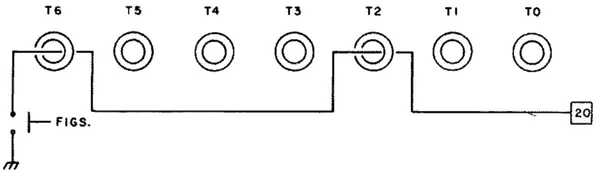

Fig. 2. FIGS encoding schematic.

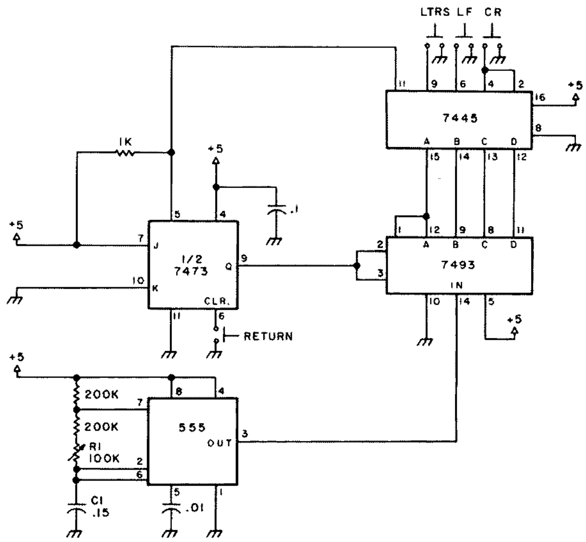

Fig. 3. Return circuit.

LTRS or FIGS toroid, T5 and T6 respectively, it is possible when depressing either the LTRS or FIGS keys to get two LTRS characters or two FIGS characters. For example, if you are in the figures case and then depress the LTRS key, the keyboard will produce a LTRS character generated by the case-sense circuit, toroid T5, and then an additional LTRS character will be generated due to the encoding of toroids T0 through T4.

Return Circuit

Now that we have the LTRS character, we must design a circuit that will in essence simulate magic fingers depressing the carriage return key twice, followed by the line feed key and, lastly, the LTRS key. The circuit in Fig. 3 will do just that. The 555 timer runs continuously. However, the 7493 binary counter will not count these pulses until the Q output of the 7473 J-K flip-flop is low. This occurs when the return key is depressed. It stays in this state until the automatic return process is over. With pins 2 and 3 of the 7493 low, binary coded digits will be sent to the 7445 decoder. This will in turn cause the 7445 to act as a distributor. Since the 7445 uses open collector outputs, they may be placed in parallel with the CR, LF, and LTRS keys to simulate the actuation of these keys. The last output of the 7445, pin 11, is used to reset the 7473. A convenient unused key that may be used for the return function is located in the extreme upper right hand corner of the keyswitch board.

Power for this circuit is derived from the keyboard's main power supply. The foil on the printed circuit board separating T4 and T5 is 5 volts with respect to ground. This is an easy and convenient point to pick off the power for the circuit.

Adjustments

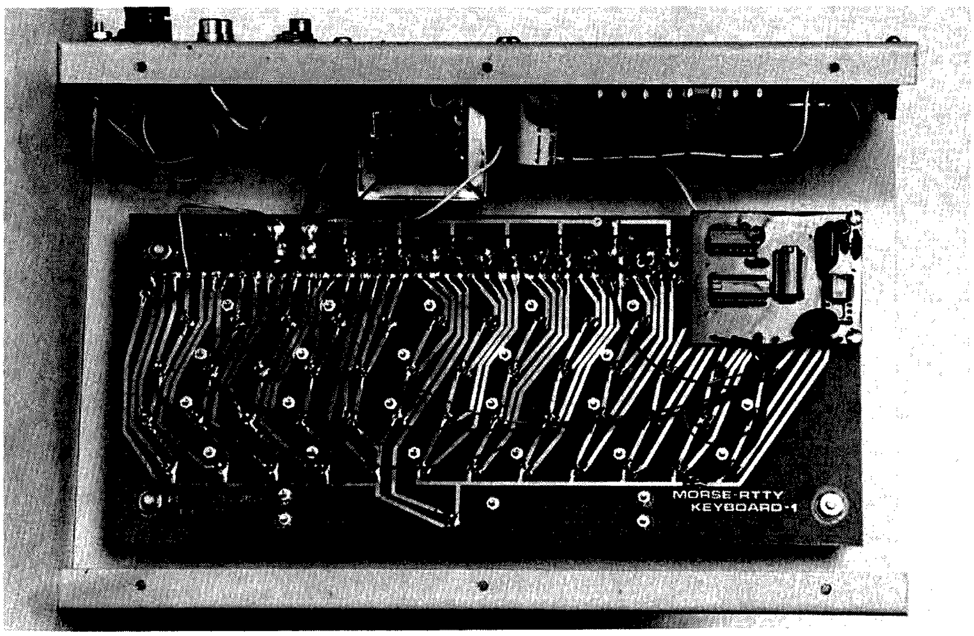
The 555 timer should be adjusted via R1 so that the CR, CR, LF, LTRS process is fast, but not so fast as to cause the characters to run into each other. The actual speed that you set the timer for will be function of the baud rate you usually operate at. For a baud rate of 45.45 (60 wpm), the timer frequency will be about 12 Hz.

The values of R1 and C1, as shown in Fig. 3, are primarily for 60 wpm operation. If you operate the keyboard at several speeds, you will want to externally vary the value of R1 as you change speeds. The main speed switch that comes with the keyboard is a 3P4T switch. While I have not tried this method, since I operate at only one speed, it seems like making use of this switch to change fixed resistors would be ideal for those wishing this feature.

Construction

The photo of the foil side of the keyswitch board shows the construction method that I used. The circuit was built on a perforated board and installed on the keyswitch board by using standoffs. The board was dipped in a coating compound, which accounts for its appearance in the photo.

The circuit has been in operation for about a year now, and I can't see how I ever got along without it. May you also have many happy returns.■



Return circuit is mounted to keyswitch board on standoffs.

Mobile Antenna Tips

-- for the beginner

This article is directed primarily to the novice – the experienced amateur won't find very much here that is new. Amateurs have been on wheels longer than CB has even existed. The techniques have changed somewhat since the advent of solid state inverters, so far as mobile power supplies are concerned, but antenna systems remain much the same as always, except for a few gimmicks to facilitate tuning.

The mushrooming popularity of VHF mobile transceivers augmented by repeaters has largely diverted attention from what this writer believes to be a fascinating, far more challenging phase of mobile operation – high power at low frequency.

It is one thing to power a ten or fifteen Watt transceiver from a twelve volt car battery and quite another to supply a 100 or 200 Watt unit. It is one thing to clamp a 19-inch whip to the gutter or mount it on the roof for 2 meter work, but something else to mount an eight foot whip and make it act like a thirty or sixty foot tower! Operating on two meters poses little in the way of noise problems: Tune up on 75 in a car and you pick up every spark plug, power line, and neon sign for miles around . . . unless you know what to do about it.

Let us, then, examine the various problems one at a time, beginning with what most mobile enthusiasts find to be the touchiest part of a mobile rig – the antenna. Amateurs have long been operating mobile on every band from 160 meters on up. We do, however, need to have an antenna that is resonant, and a resonant antenna is usually a quarter wavelength or multiple thereof. How, then, can we fit, say, a 75 meter antenna on a car? Somehow I can't imagine a Volkswagen going down the road with a 65-foot whip on the rear bumper. In fact, few mobile antennas are much more than eight feet long.

The secret lies in the fact that an eight foot whip, being less than a quarter wavelength, presents a capacitive load to the transmitter. But wait. A capacitor has at least two elements. Where is the other one?

The other side of the capacitor is the ground. In our case, it's the car body, which, incidentally, is the worst possible ground plane you can have at these frequencies. Still, it's the only ground available, so we have to make the most of it.

In Fig. 1 we see the way the capacity is distributed. While a formula exists to calculate the capacity, it is a monster, and, for eight foot whips, it has long since been calculated. See Table 1 for the values as they work out for various diameter whips.

OK, then, we have it established that a whip of known dimensions presents a definite value of capacity at the feedpoint. Now, if we add an inductance of the proper amount to resonate the whip to the operating frequency, the antenna is resonant and satisfies the prime requirement of an efficient radiator.

This inductor is added, either at the base where it utilizes the full amount of capacity and is therefore a lower value of inductance, or at the center where more inductance is required, but it distributes the antenna current more evenly. (See Fig. 2.)

The novice who has graduated from CB will recognize this as what many CBers call

	1/8"	1/4"	1/2"
6 feet	17	19	22
7 feet	19	22	25
8 feet	22	24	27
9 feet	24	27	30
10 feet	26	30	33

Table 1. Values expressed in picofarads.

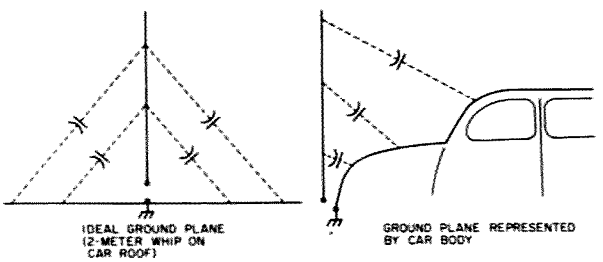

Fig. 1.

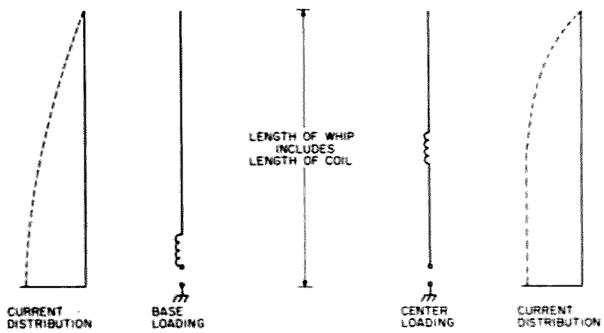

Fig. 2.

a booster coil. Whatever name it is called, it simply resonates the antenna to make it an electrical quarter wavelength. On the lower frequency bands, base-loaded antennas are preferred when the antenna is mounted on the trunk lid, and center loading is generally preferred with fender or bumper mounting. Of course, there are exceptions, mostly depending on an individual's personal tastes.

With the problem of resonating the antenna solved, there is yet another hurdle to jump. At these frequencies, an eight foot whip, even if it is resonant, presents a very low radiation resistance. Consequently, the greater part of the impedance it presents to the transmitter is resistive, and even then the impedance can be considerably lower than the 50 Ohm output of the transmitter. While some manufacturers offer lower than normal impedance cable, there is a better way to solve the problem.

An inductor or a capacitor can be connected directly across the feedpoint to *increase* the impedance to 50 Ohms. Now I know this goes across the grain of the average novice's knowledge of ac theory. However, it does work. Don't ask me why. I'll confess that I can't fully explain it even though I've written a book on antennas. The reasoning behind it is contained in a fiendish device called a Smith Chart, a round chart of reactance and impedance values which, after 25 years in ham radio, I still don't fully understand. In that respect, I belong to a very large club which excludes only engineers specializing in antennas. However, I've found to my satisfaction that it does work, and you will too, if you try it. (See Fig. 3.)

Approximate values are given for the lower amateur bands, using either base or center loading. These values do have considerable tolerance, unless you're finicky over swr. Even then, they're not extremely critical. Heathkit, for example, recommended a .001 capacitor on 75 meters, which is quite easy to get. The optimum value, however, is in the neighborhood of .00095. The .001 works quite well, however. (See Fig. 4.)

Once everything's connected, there remains the job of tuning up. I don't want to frighten you away, but, unless you have the right equipment, the initial tune-up of a low band mobile antenna can be a stinker. Don't even consider it unless you have an swr meter and a grid dipper or equivalent.

Tuning Up a Mobile Antenna

Position the vehicle where it will be clear of substantial objects (houses, trees, etc.) for a radius of at least 1/8 wavelength. Couple the dip oscillator into the base of the antenna, either by coupling into the matching inductor, or by adding a small loop of wire between the base of the antenna and the matching capacitor as shown. Adjust the telescoping top section of the antenna until the dip oscillator indicates resonance. (See Fig. 5.) It may be necessary to add or remove a turn or two on the loading inductor.

At this point I may add that in 25 years of amateur radio, I've yet to find a dip oscillator whose calibrations can be trusted. It is best to tune in the signal of the dip oscillator on a calibrated receiver so you will know where you are in the frequency spectrum.

Once the antenna is set into the right ball park with the dip oscillator, the next thing to do is to key the transmitter at low drive and measure the swr. Then adjust the telescoping section of the antenna, a quarter inch at a time, measuring the swr after each change, until you reach the point where the swr is minimum. This done, you can, if you really insist on a very low swr, juggle the matching capacitor or inductor in 5 or 10% steps to the point where swr is immeasurably low.

Sounds simple, doesn't it? The steps are very basic, yet the process is so extremely critical that it can be a frustrating experience. A quarter inch difference in antenna length at the operating frequency can push the swr up to 2 with 75 meter operation. On 160 meters, the total bandwidth with a given antenna length is scarcely enough to accommodate two SSB voice channels. If you're transmitting while in motion and a truck passes, you can see the swr momentarily go way up.

Now I've discussed the tune-up process on 75 and 160 meters where the most difficulty is experienced. As you go into higher bands, the tuning becomes less critical. Generally speaking, 40 is the more popular band for low band mobile operation. It is high enough in frequency to minimize noise problems, and low enough for impressive DX operation.

The mention of noise brings in the second biggest bugaboo of mobile operation – the biggest one after you conquer the antenna. For some reason, most natural and man-made static is vertically polarized. Since you have a vertical antenna, it is like having a noise magnet. On 75, the noise can be murder, especially when you are driving along a rural road where the power company is too tight to properly maintain their insulators and

Band	Matching Element (Base-loaded)	Matching Element (Center-loaded)
160	2000 pF, 3.7 uH	1100 pF, 5.73 uH
80	1000 pF, 1.4 uH	920 pF, 1.8 uH
40	660 pF, 0.72 uH	560 pF, 0.85 uH
20	390 pF, 0.31 uH	290 pF, 0.44 uH
15	220 pF, 0.25 uH	130 pF, 0.43 uH
CB and Up	CB – none needed. 8-foot whip naturally resonant; above CB – ¼ wave whip less than 8 feet	

Fig. 4. For a base-loaded whip, the loading coil inductance can be determined by calculating a series tuned circuit consisting of the whip capacity, the matching capacity or inductance, and the loading inductance. Use the formula:

$$L = \frac{1}{(2\pi F)^2 C}$$

For a center-loaded whip, the loading coil inductance can be determined by calculating a series tuned circuit consisting of half the whip capacity, all the matching inductance or capacity, and the loading inductance. Use the same formula.

When the antenna is inductively matched, L in the formula is the sum of the loading coil inductance and the matching inductance.

When the antenna is capacitively matched, C in the formula is the series result of the whip capacity and the matching capacity.

$$C = \frac{C_1 C_2}{C_1 + C_2}$$

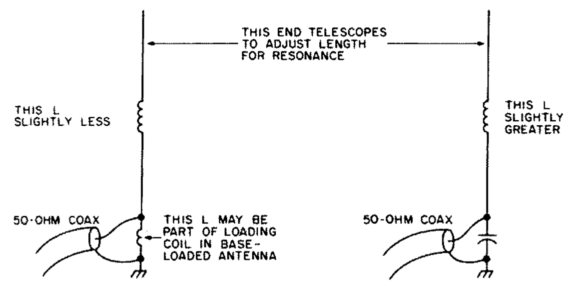

Fig. 3.

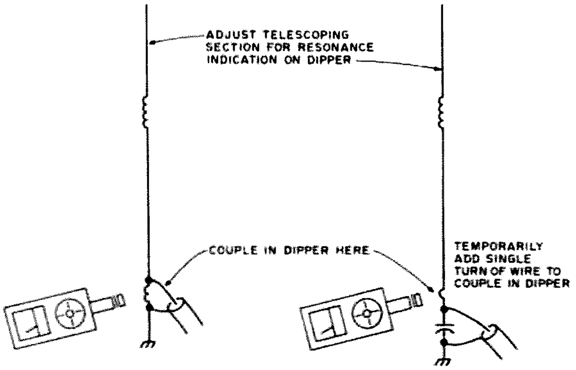

Fig. 5.

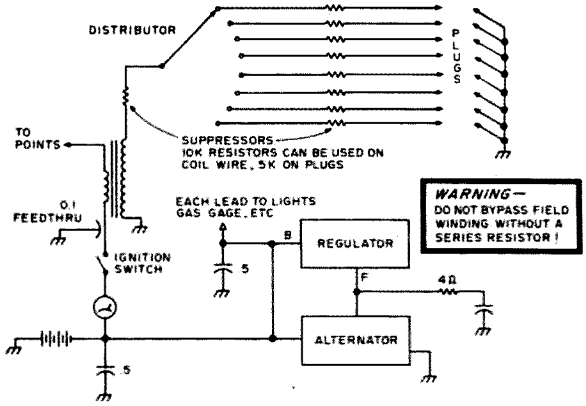

Fig. 6. For additional suppression, coil, distributor, and ignition wiring can be shielded.

transformers. Here in western New York State, for example, a certain rural road between the villages of Mount Morris and Nunda is known among mobile hams for the 20 over S9 roar it produces in their receivers. The power company tightwads must be wasting a tremendous amount of energy there.

If power lines were the only noise worry, mobile hams would have it made. Unfortunately, however, there are numerous other sources of noise. Mother Nature is one of them. I've seen the S-meter climb to over 40 above 9 when there were thunderstorms in the area. On one occasion, as I was hearing the results of a storm in the area of Buffalo 50 miles from where I was, I noticed a steady, whining roar, not too unlike the sound of rain on a tin roof. My rider said it was caused by a tornado, and I pooh-poohed the idea. The next day the papers said that a small funnel had been spotted in Erie county. It hadn't touched the ground, but my receiver had picked it up 50 miles away.

Even Mother Nature can, at times, quiet down. However, the mobile ham is carrying, in addition to his own transmitter, 4, 6, or 8 miniature spark transmitters, and he can't drive away from them. Now, you can't very easily fight the power company or Mother Nature, but you at least have a fighting chance against the noise generated by your car.

Noise can be produced, not only by the spark plugs, but also by the alternator, regulator, distributor, signal lights, horn, and even by the tires. Here is one place where the extreme popularity of CB has helped us. With all those CB radios around trying to pick 5 Watts out of the air, ignition interference suddenly gained high priority on the consumer market. Consequently, ignition suppressor kits are available almost anywhere.

Before you install ignition suppressors in your car, it might be wise to look under the hood. Some spark plugs have suppressors already built in. Some ignition wiring has suppression built in. If you add suppressors to a system that already has suppressor plugs and suppressor wiring, you might end up suppressing the spark that makes your engine go. (See Fig. 6.)

Shielded ignition kits are available. I've seen some advertised in *73 Magazine*. If this, together with all the steps recommended in Fig. 6, isn't satisfactory, there is still more you can do. Bond the hood and the car body together with lengths of heavy copper braid on either side near the hinges. Also ground the trunk lid in the same way. Connect the engine block to the car body with another length of braid, and ground the rig in the same way. Grounding the axles to the car body can suppress wheel static. Few amateurs have to take all these steps, but, on the other hand, no two amateurs have the same problems.

Finally, we come to the power supply, and it is here that the state of the art has seen the most dramatic changes in the last couple of decades. Right after World War II, solid state inverters were yet to be invented, so amateurs had to use other means of providing the needed high voltages for their rigs. Two types of supplies were used: vibrators and dynamotors, and they still provide the answer for the high-power men.

The vibrator supply used a vibrating set of contacts to chop the dc current, which was then fed into a transformer. At one time there were more different types of vibrators than there were circuits to use them in. Some even featured an extra set of contacts to rectify the high voltage. See Fig. 7(a). They had one main disadvantage in the large current demand which could quickly drain a battery.

A dynamotor is a motor operating at the battery voltage which then drives a generator to produce the high voltage. Some produce 115 volts ac, from which any rig could easily be operated. These have the disadvantage of

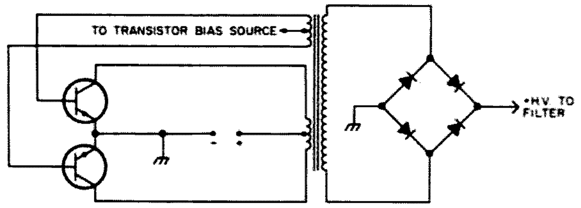

Fig. 8. Simplification of a dc to dc converter. The transistors form an oscillator circuit with the transformer providing feedback and transforming the voltage of the ac thus generated. Except for filter capacitor values, which are smaller due to the higher ripple frequency, the filter and regulation circuits are the same as in a conventional supply. Commercial manufacturers often use a more sophisticated oscillator circuit, employing a starter circuit to ensure that the oscillator always starts oscillating when the unit is turned on.

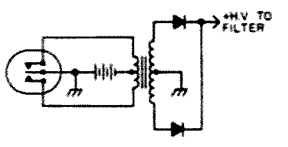

Fig. 7(a). Typical vibrator power supply. The vibrator coil and interrupter contact have been omitted for simplification.

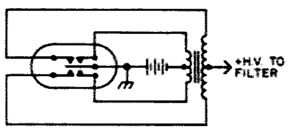

Fig. 7(b). Synchronous vibrator power supply in which an extra pair of contacts provided reactification.

high current drain as well as the arcing commutator. I've heard of a fellow in Buffalo who once tried to mount a dynamotor in his trunk. He very carefully drilled mounting holes in the trunk floor — right through the top of the gas tank. He did a neat job of installation and drove about for a while, unknowingly filling his trunk with fumes. Then he keyed the rig and blew his trunk lid clean off.

Nowadays most mobile power supplies utilize solid state inverters. An inverter is simply an oscillator, usually a particular variety of astable multivibrator circuit employing the primary of the power transformer, coupled into a feedback secondary winding. Alternating current is produced in the transformer primary by the flip-flop action of the transistors and transformed to the desired voltages, after which it is rectified and filtered in the conventional manner. Filter capacitors are usually smaller than those in ac supplies, since the oscillator operates at a much higher frequency than 60 Hz. The multivibrator circuit is preferred over a sine wave producing circuit, since the transistors in a square wave circuit waste much less power. However, the square wave requires a slightly different transformer, and the supply must be well shielded to prevent radiation of rf interference. (See Fig. 8.)

As a general rule, most hams prefer to buy their power supply and antenna. While there is nothing that exotic about these devices, the requirement of rugged construction discourages many home brew enthusiasts who don't have access to a machine shop. As for power supplies, in all too many circumstances, the transformer is designed specially for the manufacturer of a supply and is unavailable to the general public. ■

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington DC 20554

DOCKET NO. 21116

In the Matter of

Amendment of Part 2 of the Commission's Rules to prohibit the marketing of external radio frequency amplifiers capable of operation in any frequency from 24 to 35 MHz

To: The Commission

OPPOSITION TO PROPOSED RULE MAKING

The American Radio Relay League, Incorporated, the nationwide nonprofit organization of almost 140,000 amateur radio operators and enthusiasts in the United States, submits its opposition to the Notice of Proposed Rule Making released February 28, 1977 (42 F.R. 12203), and requests said proposal not be adopted.

In support whereof, the following is respectfully submitted:

I
Summary of Comments

The proposal to prohibit the marketing of external radio frequency amplifiers capable of operation on any frequency from 24 to 35 MHz, including the 28-29.7 MHz amateur band, is ill-conceived and impractical and, if adopted, not only will not reduce the unlawful use of such devices by the undisciplined Citizens Band (CB) Radio Service, but also will have a most severe impact upon and unfairly penalize the innocent, law-abiding and self-regulating Amateur Radio Service. The time has come — indeed, it is long past — for the Commissioners and the Commission's staff to concede that rules without effective enforcement are not worth the paper upon which they are written.

The state of the art is such that, unless such devices, including the components, are manufactured in strict conformance to a design either developed or specified by the Commission, any circuitry designed to prevent operation on frequencies from 24 to 35 MHz may be easily circumvented by persons with only minimal technical knowledge and experience. The Commission never has engaged in the development and design of equipment, and does not now propose to do so. In fact, the Commission may lack statutory authority to engage in such activities.

The League, as the only responsible spokesman for a substantial number of the nearly 300,000 licensed amateur radio operators in the United States, for years has been and continues to be extremely concerned about the undisciplined nature of the 27 MHz CB service, the inability of the Commission to enforce its rules, and the lack of Administration and Congressional support of the Commission's efforts. Most unfortunately, efforts of local jurisdictions to eliminate interference to television reception (TVI) from the 27 MHz CB service have had the practical effect of most severely penalizing the amateur radio operators in those jurisdictions. Numerous constructive suggestions and proposals made by the League over the years have been ignored. The League implores the Commission not to give similar treatment to the comments in opposition to the instant proposal.

The Commission is required to act in the public interest. A mere assertion that the public interest will be served by the adoption of rules such as proposed will not suffice; the Commission must demonstrate a reasonable possibility that any new rules are practical and stand a reasonable chance of producing the desired result. The League seriously doubts that any such showing can be made.

II
Circuits Intended To Prevent 24-35 MHz Operation Can Be Easily Circumvented

At the time the Commission adopted the present Section 2.815 of its Rules in 1975,[1] external radio frequency amplifiers almost without exception employed an output circuit tuned to the operating frequency. Operation on several frequency bands, e.g., the 3.5, 7, 14, 21, and 28 MHz amateur bands, usually was accomplished by switching into or out of the tuned circuit inductance, capacitance, or both.

About that time, amplifiers, both internal and external, employing broadband radio frequency transformers and capable of operation on any frequency between 3.5 and 29.7 MHz without any tuning adjustments appeared on the market. Thus, these amplifiers met the exemption of Section 2.815 and hundreds are manufactured and sold each day to CB operators.[2,3]

After explaining that the "24 MHz and 35 MHz limits were chosen so that practical circuitry could be used to achieve adequate suppression of radio frequency energy appearing on the CB frequencies" with only "a minimum effect upon the licensees of other services" (Notice, para. 8), the Commission states as follows:

> 9. Comments are also solicited concerning the practicality of such a prohibition and possible techniques which would be used to produce such an amplifier. Such comments should also address the problems associated with preventing the few unscrupulous manufacturers from including such features as accessible wiring which can be cut to provide operation on the prohibited frequencies, controls both external and internal which could provide for operation on these frequencies, or any other concepts which could be used to circumvent this prohibition.

Most unfortunately, there are not readily available at this time circuitry and techniques which cannot be easily circumvented by an unscrupulous dealer, service technician, or user, unless the Commission has the legal authority to specify certain manufacturing techniques such as, perhaps, encapsulated tuned circuits or transformers which not only are inaccessible but also cannot be substituted or bypassed. The League knows of no provision of the Communications Act of 1934, as amended, which gives the Commission authority over manufacturing design and techniques except for home television receivers which must be capable of reception of all VHF and UHF television channels.[4]

The frequency of an amplifier designed for operation on frequencies immediately below 24 MHz and employing at least one tuned circuit can easily be increased to 27 MHz by reducing either the inductance or capacitance, or both, of the tuned circuit. Reductions in inductance can be accomplished by any of several simple techniques such as increasing the spacing between turns, changing a tap, or shorting a turn. Reductions in capacitance can be accomplished by inserting another capacitor in series with the tuning capacitor, by removing a plate from a variable air capacitor, or by decreasing the meshing of plates of a variable air capacitor. The frequency of an amplifier designed for operation on frequencies immediately above 35 MHz and employing at least one tuned circuit can easily be decreased to 27 MHz by increasing either the inductance or capacitance, or both, of the tuned circuit. Increases in inductance can be accomplished by inserting magnetic material, such as a powdered iron core, in the field. Increases in capacitance can be accomplished merely by adding another capacitor in parallel with the capacitor of the tuned circuit.

The frequency response of the recently developed broadband transformer type amplifiers can best be limited by employing a low pass filter in amplifiers designed for operation on frequencies below 24 MHz, and

Continued on page 168

[1] § 2.815 *External radio frequency power amplifiers.* —

(a) As used in this Part, an external radio frequency power amplifier is any device which, (1) when used in conjunction with a radio transmitter as a signal source is capable of amplification of that signal, and (2) is not an integral part of a radio transmitter as manufactured.

(b) After January 23, 1975, no person shall sell or lease, or offer for sale or lease (including advertising for sale or lease), or import, ship or distribute for the purpose of selling or leasing or offering for sale or lease, any external radio frequency power amplifier capable of use with a transmitter operated on any frequency or frequencies between 24.00 MHz and 35.00 MHz. Type accepted external radio frequency power amplifiers as defined herein may not be marketed after August 12, 1975.

(c) The proscription in paragraph (b) of this section shall not apply in the case of any external radio frequency power amplifier capable of use with a transmitter in the amateur frequency bands 28.00-29.70 MHz if the amplifier is an integral part of a unit or device having incorporated there power amplification capability in the bands 7000-7300 kHz, 14,000-14,350 kHz and 21.00-21.45 MHz.

(d) The proscription in paragraph (b) of this section shall not apply in the marketing to another licensed amateur radio operator of any single band external radio frequency power amplifier fabricated in not more than one unit of the same model by any licensed amateur radio operator, whose license affords him the privilege of operating on amateur frequencies between 1.80 and 29.00 MHz, for his own personal use at his licensed amateur radio station.

[2] The Notice of Proposed Rule Making in this proceeding states, in pertinent part, as follows:

3. To illustrate the manner in which the new rules were circumvented, almost immediately after the Report and Order (Docket No. 20118, 40 F.R. 1243) was released, there appeared on the market a device commonly called a "broadband linear." These devices may be considered to meet the strict letter of our Rules, inasmuch as they claim to provide for operation on the frequency bands specified under our exemption. However, these devices have an even greater potential for interference due to the higher levels of spurious emissions.

4. The advertisements for external radio frequency amplifiers generally carry a specific disclaimer to the effect that "Use of this equipment is not permitted in the Citizens Band (CB) Radio Service in the United States." However, the suppliers of such equipment consistently place their advertisements in publications which cater to the CB operator and seldom, if ever, advertise in publications that cater to amateur operators who could use such power amplifiers legally. Thus, some equipment suppliers see fit to comply only with the strict letter of the law, and at the same time disregard the spirit of the law, encouraging subversion of the Commission's regulations and efforts at improving the quality of the Citizens Band for all licensees. This is our next step in increasing the level of regulation applicable to the marketing of external RF power amplifiers.

[3] A recent report in a reputable electronic industry publication stated that a single manufacturer is producing 6,000 amplifiers each week. Another publication recently estimated that at least 4,000,000 stations are operating with power far in excess of the 4 Watts output permitted by the Rules.

[4] Section 303(s) of the Communications Act of 1934, as amended, provides as follows:

§ 303. Except as otherwise provided in this chapter, the Commission from time to time, as public convenience, interest, or necessity requires, shall —

* * *

(s) Have authority to require that apparatus designed to receive television pictures broadcast simultaneously with sound be capable of adequately receiving all frequencies allocated by the Commission to television broadcasting when such apparatus is shipped in interstate commerce, or is imported from any foreign country into the United States, for sale or resale to the public.

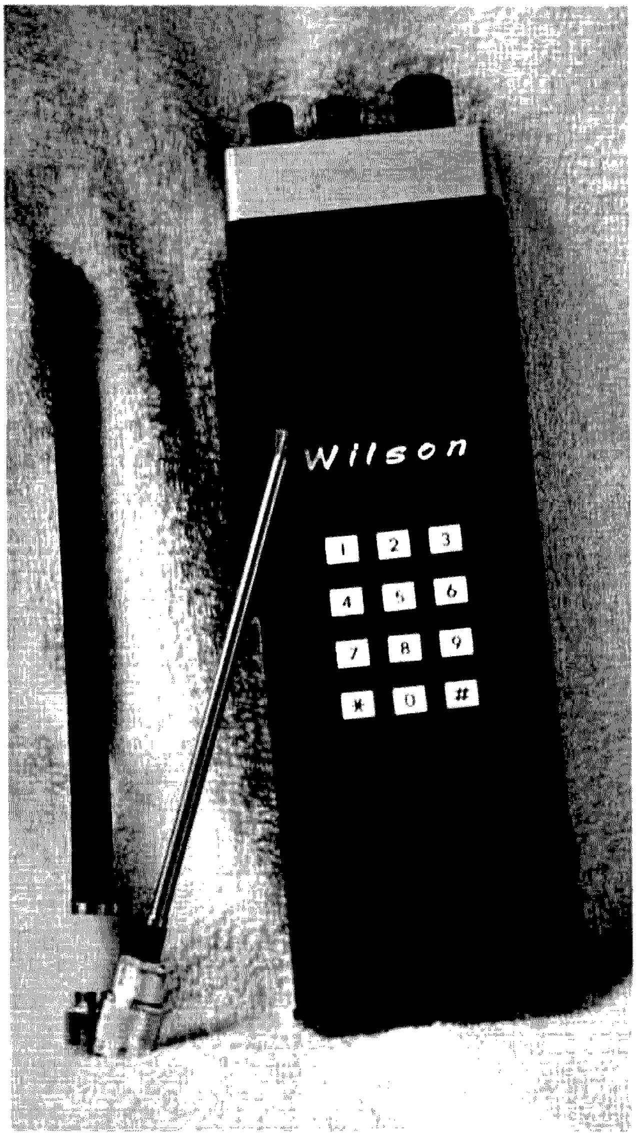
Super Wilson

-- several useful modifications



Super Wilson, with the modifications described in the text, is compact and original in appearance. The Digitran pad and full length antenna are shown.

One of the most flexible means of enjoying ham radio today is with the use of a small two meter handie-talkie. The capability of these rigs appears to be limited only by one's imagination. You can carry them anywhere and experience interference-free operation on a moment's notice. Likewise, the enjoyment of HT operation can be substantially increased if you add a few personal touches to your unit.

The following information describes such expansions that I added to my Wilson 1405 SM. These modifications are equally applicable to other handie-talkies which are presently available. You can mix and match these modifications as desired.

As I previously owned an elaborate, but low power, HT (Motorola HT 100 modified for 1 Watt on 4 frequencies as described in November, 1973, *73 Magazine*, page 77), I decided that my next HT should run the highest power reasonably available. Wilson's 5 Watt unit was the logical choice. After hassling with some minor purchase problems for a couple of months, I finally found time to modify the Wilson. Modifications included: 1) a special touchtone encoder, 2) carrier/"on" indicator, 3) extendable full length whip, 4) external antenna adaptor, 5) remote mike, 6) alternate blinker, and several other additions which will be discussed briefly at the end of this article.

Touchtone Encoder

The touchtone™ encoder consists of two parts: a small "SME" encoder manufactured by Data Signal, Inc., 2403 Commerce Lane, Albany GA 31707, and a Digitran touch pad obtained from Pipo Communications, Box 3435, Hollywood CA 90028. The "SME" was chosen because it perfectly filled the Wilson's only available free space, because the two tone levels could be independently adjusted (a necessity with the 1405 SM), and because of its previous outstanding performance.*

The newly-announced Digitran pad caught my eye because of its positive snap action, small size, and rugged construction. Mating these two units and mounting them in the Wilson can be a time-consuming project unless you follow a specific guideline similar to that described here.

Remove the HT's front cover and battery pack, and then ream a shallow trench inside the cover's back from the pad's connecting area to the cover's top. Mark the exact location for touchpad mounting/connection holes

*"The Shirt Pocket Touchtone," *73 Magazine*, Nov. 1976, pg. 58.

and carefully drill the holes. I did this by dipping the pad's bottom in the XYL's sewing chalk, and then sitting it on the HT. The white chalk left marks where each hole should be drilled. (I must have been too exacting on this because she doused me in leftover chalk shortly thereafter.)

Now secure a short length of small, flat 8 conductor cable (alpha wire makes a suitable cable), and ascertain that it fits flush in the reamed groove. Solder cable connections to the "SME", route the cable around the SME's bottom side, and tape it as shown in Fig. 1. Set the encoder and cable exactly in place as shown in Fig. 2; then trim leads and solder touchtone pad connections as shown in Fig. 1. This is also an ideal time to adjust high/low tone amplitudes for compatibility with the Wilson's frequency response. As the Wilson attenuated low frequency tones ≈3 dB (identifiable by its ability to dial all numbers except 1, 2 and 3), I paralleled the "low frequency 4.7k" resistor (R3 on Data's board) with another 4.7k resistor. This solved the problem perfectly. (Data Signal supplies complete instructions with each unit on adjusting tone levels to match rigs.) Wrap a layer of tape around the 1 MHz crystal and tape the encoder above the speaker's magnet (see Fig. 2).

Next, series connect a 500k pot and non-polarized 1 uF capacitor from the encoder output to the microphone's connection pad beside the mike. (Later the pot will be replaced with a fixed value 1/4 Watt resistor.) Surprisingly, my unit works only when this wire connects to the mike cable shield rather than the center conductor, so remember to swap connections if your unit doesn't tone. You are now ready to power up the opened HT and set tone level with the 500k pot. (I did this by actually dialing a number with the opened HT.) Now remove the pot, measure its resistance, and substitute a 1/4 Watt resistor for it. Wrap the resistor and capacitor in tape and fit them into available space. Finally, shift the encoder's position as required to avoid hitting the volume control, and reassemble the HT. Have patience and be careful not to force the case together. (Remember the tilt angle shown in Fig. 2?)

Carrier/On Indicator

Another useful modification for the Wilson HT is an incoming carrier indicator. This circuit activates a light emitting diode when a signal is on frequency, regardless of the HT's volume setting. An activating signal for this circuit is obtained from the junction of RØ66 and RØ67 in the Wilson. The best way to locate this point is with the use of a volt ohmmeter. Turn on the opened HT and switch it to an unoccupied channel. Make sure the rig is squelched. Set the VOM on a low voltage range and connect the negative lead to ground. Then, carefully touch the positive prod to the top of each resistor near Q118 and IC101. When you touch the proper resistor, the volt ohmmeter will deflect to approximately +2 volts. Unsquelching the HT will decrease this voltage to approximately zero. After locating this point, use a small soldering iron and carefully solder a small wire from that point to the input of Fig. 3.

Referring to Fig. 3, when the HT is squelched, +2 volts are applied to the base of Q1 through isolation resistor R1. This forward biases Q1, which conducts and shorts out the LED. The base voltage of Q1 rises from +2 to ≈ +6 volts during transmit; however, Q1 merely stays on. Base voltage on Q1 drops to zero when a signal is received, thus "opening" Q1 and allowing the LED to light. Current drain of this circuit is limited to ≈ .5 mA by R2. If this circuit is assembled as shown in Fig. 3(b), Q1 and R1 can be placed in the open area near Q118 and a small wire routed to an unused pin on the external mike connector. The LED and R2 are then mounted in the top of this connector, securing voltage from the appropriate pins (pins 4 and 5). A jumper is placed between the previously mentioned R1/Q1 pin and the junction of R2 and the LED. This provides incoming carrier indication. Removing this jumper allows the LED to function as a simple on/off indicator for the HT. A small cover/mount for the indicator may then be fabricated from cardboard and electrical tape.

Collapsible Antenna

A full length whip (which will substantially increase HT performance from fringe areas) is fabricated from the top part of a portable TV whip and a TNC rf connector. The whip is cut at 19 inches and crimped to hold the center connecting pin of this plug. Then the whip and pin are soldered for rigidity. A short piece of heat shrinkable tubing is affixed to the whip's bottom to prevent shorts, and the TNC's RG-58 reducer is slipped over the whip. A dimple is then added to prevent slippage, and the whip assembly (reducer, etc.) is screwed into the TNC plug. The collapsible antenna is now smaller than Wilson's rubber ducky and easier to carry.

External Mike and Antenna Connector

One of the main disadvantages of 2 meter mobile rigs is their high theft rate. Their only true means of protection is removing them every time you leave the car — no exceptions. My solution to this dilemma is to use the HT mobile and carry it with me when leaving the car. Thus,

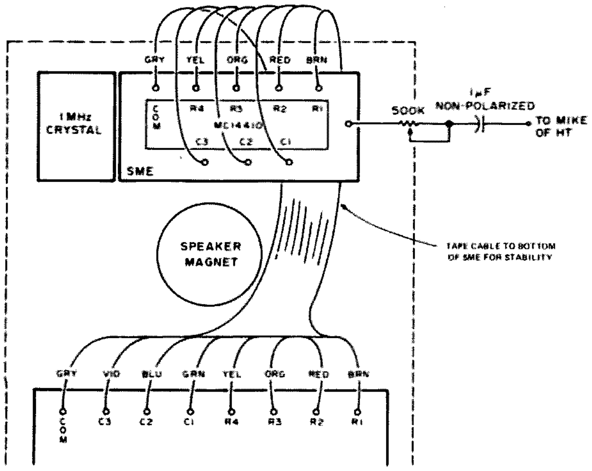


Fig. 1. Touchtone layout for inside of the HT's front cover.

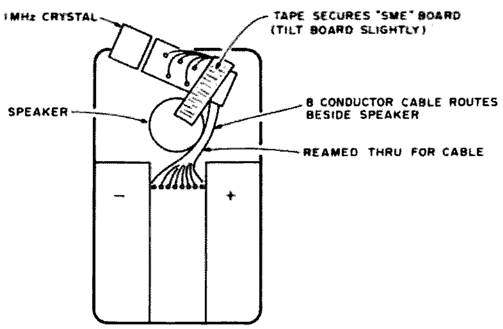

Fig. 2. A mounting suggestion for "SME" in the HT's front cover.

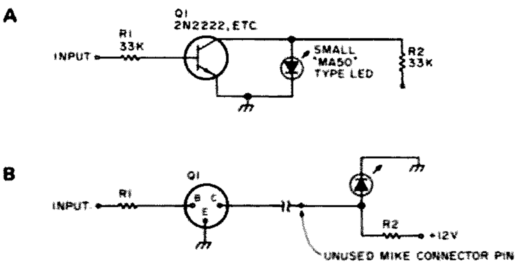

Fig. 3. a) Carrier indicator for the Wilson. b) Parts layout for the carrier indicator.

interesting QSOs are never missed due to chore stops. I merely grab the rig and continue the conversation. For mobile use, an extension rf cable is made from a 2 foot length of RG-184, a PL259 and a TNC connector. This cable and a magnetic mount 5/8 wave antenna provide very reliable mobile communications. An under-the-seat rf amplifier may be added here if desired.

Although I merely hold the complete HT during brief mobile excursions, I also fabricated a mobile mike for extended hands-free mobile use. This mike is constructed by placing a small Motorola HT mike at the end of a lightweight tube and cementing an alligator clip to the other end of this tube. Mike wires are routed through the tube and to the HT. This boom mike is clipped to my glasses during use. Transmit/receive switching is accomplished by mounting a stomp-to-talk switch near the auto's light dimmer switch. The rig can be used portable within seconds by disconnecting the external mike/PTT plug and antenna connector.

Alternate Flasher

As a special nonsense feature, I placed an LED on each side of the HT and connected them to a small 555 flasher circuit, which I mounted in the open (PL) area near the rig's bottom. The circuit for this blinker is shown in Fig. 4. This item doesn't do anything for the HT except make it look impressive. Build it small so you'll have room for more important modifications later. Component values are not critical, so feel free to use whatever junk box parts you have available. My circuit was assembled on a one inch piece of vectorboard as shown in Fig. 4. Power for the flasher is derived from the HT's battery pack. This may be accomplished by locating S202 (A and B) and moving the 1 Watt connections to the off position, and then securing flasher voltage from the 1 Watt position. The HT's hot wire is then connected through the unused squelch control switch for rig on/off functions. These flasher circuits were so enjoyable to build and use that I constructed several of them. Then I purchased some small paper maché animals with hollow insides from a local gift store and mounted the circuits in them. LEDs were placed in the drilled out eyes. A 9 volt transistor battery was placed in each unit for powering the flasher. Exclude the 2k resistor on pin 8 to +V if you use a 9 volt battery.

Latest Modifications

As mentioned earlier, I continue to modify the Wilson at every opportunity. Some of my latest ideas will now be described briefly.

Call Indicator — I often monitor one of our repeaters for calls at specific times, so I fashioned a simple set-reset circuit to indicate when this repeater was keyed "on". In the event I miss a call (or the HT's volume is low while I'm doing something else), an LED will be illuminated until it's extinguished by a reset button. As this circuit

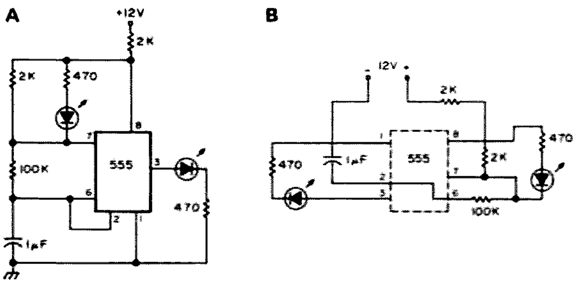

Fig. 4. a) The alternate flasher for the HT LEDs can be hamfest or Radio Shack specials. Resistor values are not critical. b) Parts layout for the flasher.

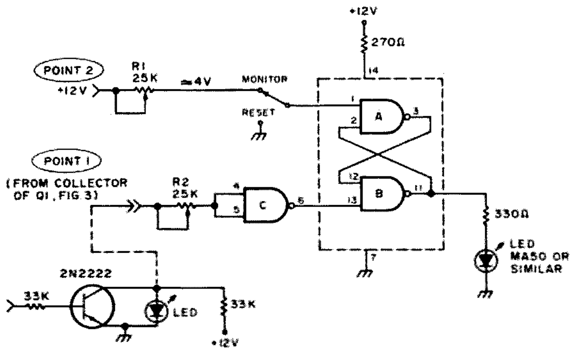

Fig. 5. Set-reset call indicator used on Super Wilson.

connects to the squelch-operated carrier indicator of Fig. 3, it can monitor any frequency to which the HT is switched. The "call LED" will illuminate when any carrier on frequency breaks squelch on the HT, but this is quite acceptable for my use.

Referring to Fig. 5, point 1 connects to the collector of Q1 in Fig. 3, and point 2 connects to the rig's +12 volts. R1 and R2 may be replaced by fixed resistors whose values are determined by the following procedure.

Set R1 and R2 to maximum before energizing the circuit, and then apply power and adjust R2 for proper "call LED" tracking (approximately 4 volts at pin 13 of IC1). Next, adjust R1 until the flip-flop resets properly (approximately 4 volts at pin 1 of IC1). Now measure R1 and R2 and replace them with the appropriate resistors. Don't forget to include the 270 Ohm resistor to pin 14 of the IC. Mount the complete circuit on a small piece of vectorboard and put it in one corner of the previously mentioned PL area.

Carry Strap/Holster — Like many of the popular HT's, my unit has two features which don't impress me — it's uncomfortable when carried on my belt, and it doesn't have an internally contained antenna. As an alternative to this inconvenience, I am having a local leather craft shop fabricate a shoulder carry strap/holster with a sewn-in 19 inch length of wire. One end of this wire will go to a connector which plugs into the HT's antenna jack. This antenna will primarily be used for receiving, rather than transmitting.

I'm also working on a mobile battery charger for the HT, and contemplating adding my Sinclair Black Watch to the unit. There's enough room available in the PL area for the watch's circuitry, and the readout can be placed above the touch-tone pad on the case front.

I see that Tec Kan has recently introduced a 6 channel scanner for the Wilson, so forthcoming modifications may be perpetual. ■

FCC

from page 163

by employing a high pass filter in amplifiers designed for operation on frequencies immediately above 35 MHz. In either case, the filter can easily be rendered ineffective by a single bypass wire. By their very nature, broadband transformers do not have sharp frequency cutoff characteristics.

There may be circuits or techniques of a proprietary nature not known to the League. If there are, it seems unreasonable to believe that they will be used voluntarily by a manufacturer not favoring the instant proposal.

A rule such as proposed may appear to a person without technical knowledge to be practical and desirable. However, as illustrated above, there are many ways in which an unscrupulous dealer, service technician, or user can circumvent the rule.

III
Restriction On Dissemination Of Information As To How The Rule Can Be Circumvented Would Be Unrealistic And Impractical And May Violate The First Amendment To The Constitution

The notice appears to invite comments as to whether the Commission can prohibit an unscrupulous manufacturer from including in the operation, instruction, or service manual information as to how the prohibition against operation between 24 and 35 MHz can be circumvented. Even if the Commission has the authority to dictate or restrict the content of such manuals, and the League knows of no provision of the Communications Act granting such authority, the information most certainly will be widely disseminated by other means, such as magazine articles, mailing pieces, telephone, and word of mouth. Violation of First Amendment constitutional rights undoubtedly would be raised should the Commission undertake any such restrictions.

IV
Small Scale Garage and Basement Manufacturing Would Occur Even If Circuits And Techniques Are Available To Achieve The Commission's Objectives

The components necessary to build an amplifier for use on the 27 MHz CB band are readily available and relatively inexpensive. Design and construction articles already are contained in numerous publications. Is it not reasonable to expect that many qualified persons will want to earn extra money by building amplifiers on a small scale basis? The League thinks so. Instead of having only a limited number of relatively large unscrupulous manufacturers, the Commission will be confronted by a very large number of small unscrupulous manufacturers as well as by countless thousands of home constructors. Once again, the rule would not achieve the intended result.

V
Prohibiting The Marketing Of External Power Amplifiers Capable Of Operation Between 24 and 35 MHz Would Not Prevent Illegal High Power Operation At 27 MHz

The maximum output of 27 MHz transmitters is 4 Watts average power for the amplitude modulation (AM) mode and 12 Watts peak envelope power (pep) for the single sideband suppressed carrier (SSB) mode. If the primary objective of the instant proposal is to prevent operation with higher powers, that objective cannot be achieved by limiting the frequency range of external radio frequency amplifiers as proposed in the Notice.

Many manufacturers, both domestic and foreign, now produce HF transceivers for operation on all amateur frequencies between 3.5 and 29.7 MHz with output powers from 50 to 500 Watts. The ready availability of such transceivers led the Commission in 1976 to increase the maximum input power to the final stage of transmitters operated by Novice Class operators from 75 to 250 Watts [Section 97.67(d), Docket 20282]. Within the last few months, transceivers with single sideband (SSB) output powers in excess of 1,000 Watts pep have appeared on the market and have been widely advertised in magazines catering to CB operators. Almost all of the HF transmitters can be operated in the 27 MHz CB band and on the frequencies between that band and the 28 MHz amateur band merely by substituting a quartz crystal, which can be purchased for $3.95 to $7.95, or by re-adjusting one tuned circuit. Tens of thousands of transceivers now are operated in violation of the Commission's rules on frequencies within and immediately above the 27 MHz CB band. If the primary purpose of the proposal of this proceeding is to limit or prevent 27 MHz CB operations with powers in excess of that authorized by the rules, it cannot be achieved by adoption of the amplifier proposal of this proceeding.

VI
Type Approval, Type Acceptance or Certification Would be Impractical

In companion Notice of Proposed Rule Making in Docket 21117 (42 F.R. 12204), released concurrently with the Notice in the instant proceeding, the Commission has proposed amendment of Section 2.983 of its rules to require type acceptance of equipment marketed for use in the Amateur Radio Service. Although the League is submitting separate comments in response to that Notice, a few observations at this time are appropriate.

The purpose of type approval, type acceptance or certification is to assure that certain equipments meet minimum specifications and standards set forth in the Commission's rules. For example, in the Amateur Service, spurious radiations from transmitters and oscillator circuits and receivers are legitimate concerns of the Commission. However, there is a substantial question as to whether the Commission's statutory authority extends beyond the electrical and safety characteristics to mechanical design. To illustrate, if an external amplifier which employs a low pass filter to prevent radio frequency output on frequencies above 24 MHz *meets* the specifications and standards for fundamental frequency and spurious radiations, can the Commission nevertheless *refuse* to grant type approval, type acceptance, or certification because the design permits the filter to be easily bypassed, thereby making possible operation at 27 MHz? The answer appears to be that the Commission has no such authority and must grant type approval, type acceptance or certification. This subject is discussed in greater depth in the League's comments in response to the Notice in Docket No. 21117.

VII
Construction Of Single Amplifiers Should Not Be Limited To Operators With General Or Higher Class Licenses

The Commission recognizes that many amateurs construct their own equipment and proposes that "to lessen the impact of this proposal upon the amateur operator who wishes to use the 10 meter [28 MHz] band, . . . a licensed amateur operator may construct one unit of a particular model amplifier for use at his own station" which he may also sell to another licensed amateur operator. Comments are invited to the proposal that "construction of these amplifiers will be restricted to those operators with a General or higher class license" (Notice, para. 10).

If the proposal to prohibit the marketing of amplifiers capable of operation between 24 and 35 MHz should be adopted, the League supports adoption of the exemption for amplifiers constructed by a licensed amateur for his own use. However, the League objects to the proposal that the amateur hold a General or higher class license.

The Commission's proposal is not limited to external radio frequency amplifiers having certain characteristics such as the radio frequency input and output powers. An ever increasing number of amateurs are specializing in low power (QRP) operation with transmitter powers up to 5 Watts. At least one QRP manufactured transceiver and at least one QRP transmitter kit are available, and QRP contests are conducted on a regular basis.

The limitation of amplifier construction to those holding a General or a higher class license would work a severe and unfair hardship upon Novice class operators. For example, many Novices operate QRP transmitters in the CW subbands of the 3.5, 7, 21 and 28 MHz amateur bands. Should the Commission's proposal be adopted, the Novice no longer would be permitted to construct an external amplifier capable of increasing his station's power from one or three Watts to fifty or one hundred Watts in the 28 MHz band, even though he may operate with an input power of 250 Watts in that band.

The Commission observes that consideration was given to "the higher degree of technical competence and experience which must be demonstrated to obtain such a (General class) license" (Notice, para. 10). A radio frequency amplifier, particularly one with relatively low power to cover two adjacent amateur bands, such as the 21 and 28 MHz bands, is a simple device which requires little technical competence or experience to construct.

Limiting construction of amplifiers to certain classes of operators would be unreasonable and unfair.

VIII
The Feasibility Of Prohibiting Sale of Amplifiers To Other Than Licensed Amateurs Should Be Explored

Chairman Richard E. Wiley concurred with considerable reluctance to the issuance of the Notice in this proceeding, and expressed the hope "that the comments we receive will suggest other and better alternatives to the Commission's proposals" and, at the same time, "recognize the tremendous task facing the FCC in regulating CB radio which, in the space of only 2 years, has grown from 50,000 license applications a month to over one million applications in January, 1977, alone."

From time to time in recent years, individual amateurs have suggested that dealers in amateur equipment be prohibited from selling amateur and amateur type equipment to persons not holding valid amateur licenses. A few dealers have adopted such a policy and practice. Most unfortunately, it appears that voluntary compliance with such a policy on a large scale cannot be achieved.

Two petitions for rule making proposing rules to permit the sale of amateur type equipment only to licensed amateurs now are before the Commission awaiting action: RM-2839, filed by the San Antonio Repeater Association on February 9, 1977, and RM-2866, filed by Frank W. Napurano, licensee of Amateur Radio Station K2OKA, on March 24, 1977. The R. L. Drake Co. has filed comments in response to RM-2839 which set forth a comprehensive and detailed plan to provide such controls. Numerous comments in response to the Notice in this proceeding suggest similar controls. Some of the respondents also have suggested that all amplifiers and transceivers bear permanently affixed serial numbers and a central registration office be established to aid in enforcement activities.

Although the League has considered the feasibility of prohibiting the sale of external radio frequency amplifiers, transmitters and transceivers to persons not holding a valid amateur license, it has serious doubts as to the statutory authority of the Commission to adopt such rules and practices.

The League strongly recommends that the Commission process with high priority the two petitions, RM-2839 and RM-2866, and either issue a notice of inquiry and notice of proposed rule making or deny the petitions with a statement of the reasons for the action. Should a denial of the petitions be based upon lack of statutory authority to adopt and enforce any such rules, requests for appropriate legislation then can be presented to the Congress.

IX
Effective Enforcement Of The Present Rules Is The Only Solution To The Problem Of Illegal Operations

The Commission has been aware of the widespread misuse of the 27 MHz CB and adjacent channels by unlicensed stations and by stations operating with powers in excess of that permitted by its rules since shortly after the Class D Citizens Radio Service was established in 1958. The Commission's requests to Congress for legislation granting it authority over unlicensed stations and equipments have gone unanswered for several years. Requests for funds to mount an effective are wide or nationwide enforcement program have been unproductive. The Commission is the laughingstock of millions of licensed as well as unlicensed 27 MHz CB operators. The chances of a CBer being apprehended for unlawful operation are far less than a motorist being apprehended for violation of the national 55 mile per hour speed limit in a state where only token enforcement is practiced.

Amateur radio operators have expressed their concern over the ever increasing unlawful operations in and close to the 27 MHz CB band over the years, and have been expecting the CBers to overrun the amateur bands like swarms of locusts and grasshoppers. Advance intruders already have appeared in the amateur bands, some using amateur callsigns either assigned to others or unassigned, and some operating only with pseudonyms or "handles" or phony callsigns.

Effective enforcement is the only solution. Millions of CB operators are losing respect for law and order by the excesses on the CB band. The Commission must find some way to impress upon Congress the need for funds to mount an effective enforcement program, not so much against the individual operator who may violate relatively minor rules, but against the flagrant individual violators, manufacturers, and sellers of the high power equipment used for such unlawful purposes. Perhaps legislation granting the Commission additional enforcement powers also is necessary. But one thing is certain: Adoption of unenforceable rules such as those proposed here will simply make matters worse and make even more difficult, if not impossible, the adoption of corrective measures in the future.

X
Conclusions

There must be some reasonable expectation that a rule will be effective before it can be adopted (Home Box Office, Inc., v. FCC, 1977). It is respectfully submitted that no useful purpose will be served by adopting a rule prohibiting the manufacture or sale of external radio frequency amplifiers capable of use between 24 and 35 MHz as proposed in this proceeding. Termination of this proceeding is respectfully requested.

Respectfully submitted,
THE AMERICAN RADIO RELAY LEAGUE, INCORPORATED
Robert M. Booth, Jr.
General Counsel

COMMENTS ON DOCKET 21117

Assuming Docket 21117 is adopted by the FCC in some form or another, manufacturers of amateur radio equipment will be faced with a number of difficult, and hard to answer problems.

For Example:

1. Will conformance of a product to federal standards at the time of manufacture provide an inherent defense against product liability suits?
2. Is there any statute of limitations to define how long after manufacture (or original purchase) that a manufacturer remains liable for the performance specs?
3. Will modification or alteration of the equipment relieve the manufacturer of further liability?
4. Does misuse of the equipment provide a defense?
5. Must defects be present at the time of manufacture in order to justify claims, or will manufacturers remain liable for developed defects?

These questions, and their answers, should point up a serious oversight in the FCC's thinking. Other commercial services do not "encourage experimentation" by owners or operators. By placing the responsibility for transmitter adjustments in the hands of licensed commercial radiotelephone/radiotelegraph operators, the responsibility for spurious, or incorrect, transmitter adjustments is limited to that known, tested, and (presumably) qualified group.

Contrast this with the typical amateur, as we know him, and it readily is apparent that equipment manufacturers are headed into stormy waters. Modification is the norm in the amateur service, misuse is common, and twenty-year-old equipment can be found in almost any ham shack.

Let me ask you (with what we now have from the FCC) if the manufacturer of a twenty-year-old antenna tuner is liable for a corroded screw terminal that causes excessive harmonic/interference, resulting in the ham being fined $500.00.

Grandfathering? That is no defense in 1987 for what we are producing in 1977. Nor will it be a proven defense until one or more of us is sued and successfully defends himself. From some ham whom the FCC fined 500 (or 5,000) bucks, and he blames the equipment.

To protect themselves from future legal hassles, manufacturers will be forced to increase their product liability insurance, and build a fund to provide legal defenses against future lawsuits by amateurs and various agencies of the government in addition to the FCC. With Docket 21117, OSHA, consumer groups, Customs, and God knows who else will have an interest in ham radio that they never saw before.

The net result of Docket 21117 will be to increase the cost to the purchaser, by enough to cover the extra QC recording, outside engineering lab work, UL approvals, product insurance premiums, legal defense fund, and the engineering freeze that is sure to occur in amateur equipment (as it has in commercial equipment).

These things frequently have a domino effect. By making it necessary to precisely identify the break-in point where a capacitor made by AEROVOX is substituted for an identical (or better) one made by TOSHIBA, the manufacturing engineer resists the substitution, and will only do it if the original is unavailable. Production is stopped totally at times in military work for this precise reason.

As a manufacturer, you must prepare your defense in advance by having absolute configuration control, with supporting documentation to prove that each change was necessary and justified. Do you now have a configuration control system? If not, then expect to add on that cost, too. How long should you retain the records? As long as you are liable, and right now there *is* no answer.

What are your chances of being nailed? Ask General Motors. They substituted equal or better Chevy engines for Pontiac and Olds engines. Their bill (so far) is over a million dollars.

Now, Docket 21117 is serious, and the amateur service was exempted from type acceptance requirements for very valid reasons. Amateurs are encouraged to experiment, develop new approaches, and modify their gear; commercial users are not.

QST runs "Hints & Kinks," and so does *Ham Radio, CQ, 73* and many, many non-ham publications such as *Popular Electronics*. Indeed, Yaesu is "blessed" with a group called the "FOX-TANGO CLUB," which monthly issues quantities of modifications, some of which even work. Will Yaesu be liable if some "FOX-TANGO" mod results in out-of-spec operation? Or a *73* mod? Or a *QST* kink?

These are the questions that we must press upon the FCC, hopefully to encourage them into some other, less harmful, course of action to solve their interference problem.

It is important to realize that the domestic issues presented so far pale into insignificance when viewed in terms of WARC '79. With amateur radio interests going unrepresented to any significant degree, the very real possibility is present that ham radio could go to a new philosophy entirely.

If, as one country suggests, HF operations were chopped to 20 kHz limits below 30 MHz, manufacturers can look forward to new designs and a shift away from traffic handling, DX hunting, and probably phone operation, because who would assign 3 kHz SSB slots into a 20 kHz band? CW would be the only practical mode — probably coherent CW, of the nature described recently in one of the amateur magazines. Lucky you!

Above 220 MHz? Fine, but with the loss of our wide choice of satellite frequencies, not much DX with countries who cannot come up with good UHF-SHF gear.

Lots of changes are coming, and soon.

What can you as a manufacturer do? You can band together in organizations like ARMA, to give you a means of doing things like lobbying and passing favorable rulings.

You can set up formal QC organizations and initiate a configuration control system that will withstand a legal assault.

You can begin examination of your advertising, to be sure that no legal grounds exist on which the FTC or consumer groups could bring suit. Have your lawyer *and* your chief engineer approve every ad before it is released.

Place your ads where the publisher is not hostile to manufacturers. Does that sound silly? It's not, because (as strange as it seems) some magazines are just bleeding us to finance other operations. You can sense the contempt in which they hold "store bought" equipment.

As far as I know, only one magazine has begun to actively support ARMA, and they even help the smaller advertisers make up ads. This is not to imply that the rest are hostile — just derelict, indifferent, or not comprehending the importance of what the ham radio manufacturing industry is undergoing.

Our company is not the smallest in the business, but we will look long and hard at our 1978 advertising budget, and we advise you to do the same. If the amateur population increases at 30,000 per year, this figure (when converted to dollar purchases and divided up among all companies from our size to the Ma and Pa outfits, plus sales of used equipment to new hams) simply does *not* represent significant, or even noticeable, growth. Unless everyone who struggles to make a dollar in the ham market presents a united front, the harassment that amateur radio is undergoing, and will be undergoing in the next few years, could spell its demise as an industry.

This united front must include not only the few manufacturers that exist within the U.S. and in foreign countries, but amateur radio dealers, the electronics publications (with spearheading by the ham publications), and grass roots hams. And, we cannot get hopeful about what the general amateur population might do to help, as it consists of a rather inarticulate group, largely young people or retirees — by tradition, they expect that someone else will come to their salvation. Doubtless the military will preserve their own out-of-ham-band frequencies for MARS use, but there are now only several thousand hams involved with this special service, and their pool of operators will diminish in proportion to the total ham population.

I want to emphasize as strongly as possible that we must press forward as soon as practicable with our ham ambassador program, or risk not having an industry at all! Without amateur frequencies, FCC actions affecting the amateur manufacturer become moot.

We must elicit answers from the FCC regarding precisely what the basis will be for acceptance/rejection of new designs of amateur gear, and what the requirements are for records (and how long must they be kept?). How detailed must a configuration control system be, with respect to prints, manuals, and engineering change orders?

The liability question must be studied, and limits put into the rules to avoid those problems now being experienced in other industries.

In short, we have two major projects, and possibly a third.

It has been put forward for discussion that amateur radio is totally represented to the world by the ARRL, and that a second organization, providing an alternative for individual amateurs, should be brought about in the near future.

Naturally, the ARRL is opposed to this idea, on the basis that it would provide a divisive picture to the FCC and the world, and result in damage to the ARS as a whole.

Several other arguments against a second organization have been put forth, but the possibility of damaging the amateur service by polarizing individual hams into two hostile camps is the only serious consideration we find valid.

Currently, the ARRL claims about 120,000 paid members, or roughly 40% of the 300,000 licensed amateur population.

The "sole and only" approach has been successful in the past, and anyone who thinks the ARRL has not made solid contributions in the amateur radio service simply has had his head in the sand.

Without the ARRL, DX awards, satellites, conventions, and a yard-long list of services would not have occurred at all, so it is small cheese indeed to cry that the ARRL is bad for ham radio. It is no exaggeration to say that none of us would even be in this business today if it were not for the League developing a market for us.

But the monolithic structuring of the ARRL has led to occasional blunders, and like most organizations (including my own), we (and they) have no desire to parade our failures, screw-ups, and outright bummers into public view.

Burying one's past mistakes is only human. Indeed, doctors do it all the time. But doctors are trained to learn from their errors, and occasionally even account legally for the malpractice.

Lacking checks and balances, the ARRL has shown increasing tendencies to turn a deaf ear to any voice west of the Allegheny Mountains, and for years has been laughingly pointed to as "living behind the codfish curtain."

So perhaps in the fullness of time, the ARRL has reached a "critical mass."

If the ARRL represents 40%, who represents the other 60% of the amateur population?

Would a new amateur radio group attract its membership from the ARRL's 40%, the uncommitted 60%, or both? Or neither? One of the first things to do would be to survey the amateur population and see if hams themselves want to join any new group.

The form of a "second ARRL" would probably determine its success or failure, so a great deal of thought should be given to where the ARRL must compete head to head, and to what areas the new organization would find itself exclusively owner of.

For example, the ARRL cannot lobby, so that would become an exclusive feature of the second group. Both would purport to represent amateurs, so a head to head contest for bodies would be natural. However, the ARRL would remain the sole purveyor of such invaluable technical aids as they now produce, along with their panoply of awards, certificates and so forth.

The ARRL has made it quite inviting for a new organization to gestate. They increased their dues again, as well as advertising rates, travel expenses, and salaries.

In a word, they are "fat."

Enough of the mechanics involved; what positive good would occur that would make ham radio prosper and grow?

I cannot answer that question to my own satisfaction, and admit that until more information is available, a second organization would be hard to endorse.

Nevertheless, it is essential that we in ARMA take up this question and give it the careful study it deserves. We, as a group, could make it happen, if we choose to do so,

and if it appears to be good for amateur radio to do so, we should grasp the nettle firmly and move with firmness and dispatch to start the ball rolling. If on balance it appears harmful to get a second organization into the act, then the matter should be dropped.

So the third major question is here: Should ARMA open up a second amateur radio organization, or not?

Thank you for your patience, your attention, and the privilege of sharing these thoughts with you.

Bernie Towers
Yaesu Radio Corp.

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington DC 20554

DOCKET NO. 21117

In the Matter of

Amendment of Parts 2 and 97 of the Commission's Rules to require type acceptance of equipment marketed for use in the Amateur Radio Service

To: The Commission

OPPOSITION TO PROPOSED RULE MAKING

The American Radio Relay League, Incorporated, the nationwide nonprofit organization of almost 140,000 amateur radio operators and enthusiasts in the United States, submits its opposition to the Notice of Proposed Rule Making released February 28, 1977 (42 F.R. 12204), and requests said proposal not be adopted.

In support whereof, the following is respectfully submitted:

I
Summary Of Comments

The reasons given by the Commission for proposing type acceptance of equipment marketed for use in the Amateur Radio Service are (1) to control the design of transmitters, transceivers, and external radio frequency amplifiers to prevent their unlawful use with or without modification in the 27 MHz Citizens Band Radio Service, and (2) to "protect" the amateur bands from "store bought" equipment that does not at least meet minimum technical standards.

The League opposes adoption of the proposals for the following reasons: (1) the desired result, i.e., control of the design and marketing of transmitters, transceivers, and external radio frequency amplifiers to prevent their use in the 27 MHz CB band, would not be achieved; (2) no significant need for type acceptance of amateur equipment has been shown and none is known to the League; and (3) the statutory authority of the Commission to control the design and related characteristics of amateur equipment without specific legislation by the Congress is questionable.

II
Amateur Equipment Usually Is Designed To Cover Frequencies Outside The Amateur Bands

Most HF equipment now manufactured for sale to and use by amateurs is designed to cover frequencies outside the present amateur bands for one or more of the following reasons: (1) to facilitate design and construction; (2) to make possible operation of the amateur station as a Military Affiliate Radio System (MARS) station on government frequencies usually adjacent to the amateur bands[1]; (3) to provide for changes in amateur bands by World Administrative Radio Conferences[2]; (4) to permit operation on amateur bands available for use in some countries but not in the United States[3]; and (5) to permit use of equipment by other services with but minor modifications.[4,5]

The many variations in design and the flexibility of operation of HF amateur equipment makes impossible effective measures to prevent operation of such equipment with but minor modification or adjustment in the 27 MHz CB band. Restrictions on the design of HF amateur transmitters and transceivers, and perhaps of external radio frequency amplifiers, even if possible and practical, would eliminate the flexibility necessary to (1) accommodate future changes in the amateur bands, (2) participate in MARS, and (3) participate in Alaskan emergency communications on 4,383.8 kHz. Restrictions also would seriously inhibit the design and development of amateur equipment and the usefulness of such equipment to other services and, in time of national emergency, to the government.

III
The Commission's Objectives, To Prevent Use Of Amateur Equipment On 27 MHz CB Frequencies, Would Not Be Achieved

The primary purpose of the proposal to require type acceptance of amateur equipment is to prevent use of such equipment for illegal operation in the 27 MHz CB band and adjacent frequencies. In its Notice, the Commission states:

> 2. . . . The vast majority of amateurs now utilize commercially produced equipment, although the individual amateur operator often modifies this equipment to alter or improve its capabilities. This trend has resulted in a proliferation of equipment makes and models, and among them are now several types not only operable on amateur frequencies, but also, with no or only minor modifications, capable of operation on the 27 MHz CB frequencies. This quasi-CB equipment, as well as all other amateur equipment, does not now fall under the Commission's regulations on type acceptance and marketing, and we believe that the time has now come to amend our rules accordingly.
>
> ***
>
> 4. *We visualize the type acceptance requirement as a method to bring to our attention the quasi-CB equipment of the type mentioned above.* At that time, we can determine the suitability of permitting the marketing of the equipment. Under our type acceptance requirements, before a grant is made, we must determine not only that the equipment meets the applicable technical standards, but also that a grant of type acceptance would be in the public interest. Conditions which we would look for in deciding if a type acceptance grant should be made include, but are not limited to: any accessible wiring which, when cut, would allow operation on a frequency where use of the equipment is not permitted; the providing of circuit boards or similar circuitry to facilitate the addition of components, the purpose of which would be to change the equipment's operating characteristics in a manner not permitted under our rules; or, any internal or external adjustments or controls which are provided to facilitate operation in a manner not permitted under our Rules. Therefore, if a device met the technical requirements of the ARS (Part 97) but was presumably intended for illegal use in another service, type acceptance could be denied and the manufacturer would be denied the right to market that device. The manufacturer of devices intended for legitimate use would not be affected by this proposal. Comment is requested concerning specific details which should be placed in our rules concerning the conditions under which type acceptance could be denied. (Emphasis supplied.)

As shown in the discussion in the preceding section, almost all HF amateur transmitters and transceivers fall within the Commission's definition of "quasi-CB equipment." Just because the equipment may be easily adjusted or modified to operate on frequencies outside the present amateur bands, even including the 27 MHz CB band, does not and cannot create a presumption that the manufacturer intended that the equipment would be used illegally in the 27 MHz CB band.

It is apparent that the Commission contends that it may refuse to grant type acceptance to equipment which fully "meets the applicable technical standards" if there are some features of the design and construction it does not like. The League respectfully disagrees and submits that any other characteristics which might possibly bring about a refusal to grant type acceptance must be clearly and concisely stated in the rules. In the absence of such rules, how would a manufacturer know what standards he must meet to obtain type acceptance, how could the Commission defend itself against charges that refusal to grant type acceptance was arbitrary and capricious, and how could a court review upon appeal?

In the last sentence of paragraph 4, the Commission asks for "specific details which should be placed in our rules concerning the conditions under which type acceptance could be denied."

The League can offer no such suggestions, for the following reasons: *First*, present day design and construction practices provide the frequency flexibility necessary for full and complete amateur operation now and in the future. *Second*, as discussed later in these comments, there is serious question that the Commission has statutory authority to adopt and apply restrictions on the design and construction of amateur equipment.

The inescapable fact is that the Commission's objectives, to prevent use of amateur equipment of 27 MHz CB frequencies, cannot be achieved through the guise of type acceptance.

IV
Statutory Authority To Use Type Acceptance To Regulate Electrical and Mechanical Design Is Doubtful

It is apparent from paragraph 4 of the Notice, particularly the third and fourth sentences, that the Commission believes it has the statutory authority to withhold grant of type acceptance even though the equipment fully "meets the applicable technical standards."

The League knows of no provision of the Communications Act of 1934, as amended, or other statutes, which gives the Commission authority to regulate the electrical and mechanical design and manufacturing techniques of equipment, with but two exceptions. The first exception is where safety of life or property may be endangered. The second is Section 303(s) of the Communications Act which granted the Commission the authority to adopt and enforce rules requiring that all television receivers be capable of adequately receiving all VHF and UHF television broadcast channels — the all-channel receiver bill.

It appears from the third sentence of paragraph 4 that the Commission believes it has authority to determine that equipment not only "meets the applicable technical standards, but also that a grant of type acceptance would be in the public interest." "The public interest" is a nebulous standard. Under the guise of the "public interest" and nothing more, an agency could act in a most arbitrary manner. It is respectfully submitted that equipment which meets all "applicable technical standards" and presents no safety hazards must be granted type acceptance without a supplemental "public interest" conclusion.

The public interest required that television receivers be capable of receiving all VHF and UHF channels. Without such receivers, the demise of early UHF stations was imminent, and growth of an effective UHF television service was doubtful. The Commission concluded in 1961 that it lacked authority under its "public interest" power to adopt and enforce regulations requiring all-channel receivers. If the Commission found it necessary to seek statutory authority to adopt rules for all-channel television receivers, it would appear that statutory authority must be obtained from the Congress to adopt and enforce rules to prevent amateur equipment, particularly transceivers and external amplifiers, from being capable of operation in the 27 MHz CB band.

The League respectfully suggests that this matter be carefully considered before any rules such as proposed here are finalized. The size of the amateur market is sufficiently large that the possibility of an appeal is great should the proposals of this proceeding be adopted.

V
Need For Type Acceptance Has Not Been Shown

Some need for adoption of a rule must be shown or be apparent. Except for the desire to prevent use of amateur equipment for unlawful 27 MHz CB operation discussed in paragraphs 2 and 4 of the Notice (which are quoted earlier in these comments), the only need or justification appears in general language in paragraph 5 of the Notice:

> 5. Although the rules will continue to place the responsibility for meeting high technical standards upon the individual amateur, and we will continue to encourage experimentation and testing of equipment, we believe that those marketing amateur equipment must share in the responsibility to provide equipment capable of meeting these standards. Moreover, type acceptance of commercially marketed equipment does offer certain benefits to the amateur community. In addition to closing the amateur "loophole" that allows illegal CB "linears" to be openly advertised and sold, these requirements will also assist in preventing the marketing of inferior equipment to amateurs. The amateur band will be protected from "store bought" equipment that does not at least meet minimum technical standards.[6] This should result in fewer occurrences of interference to television receivers, other home electronic equipment, and other radio services including the amateur service itself.

It has been the League's experience, particularly in recent years, that amateur

[1] Some MARS frequencies and bands are adjacent to the HF amateur bands, and others are scattered throughout much of the HF portion of the spectrum.

[2] The League has urged the Commission to support a proposal that the United States propose new amateur bands in the vicinity of 10, 18 and 24 MHz at the WARC to be held in 1979. Tentative proposals prepared by the Commission contemplate the following changes in the present HF amateur bands: from 7.0-7.3 MHz to 6.95-7.25 MHz; from 14.0-14.35 MHz to 13.95-14.4 MHz; from 21.00-21.45 MHz to 20.95-21.45 MHz; and a new band, 25.76-25.86 MHz (Fifth Notice of Inquiry, Docket 20271, released May 23, 1977).

[3] The band 26.96-27.23 MHz was withdrawn from amateur use in the United States in 1958 and made available for the Class D Citizens Radio Service.

[4] Amateur equipment of at least one manufacturer was purchased by the Department of Defense during the Viet Nam action and is widely used at the present time. The amateur equipment of another manufacturer is used in the Maritime Mobile Radio Service with only minor modifications. Sources of equipment are readily available in times of national emergency.

[5] Amateur stations in Alaska may operate on 4,383.8 kHz with a maximum power of 150 Watts for emergency communications with other authorized stations in and within 50 nautical miles of Alaska.

[6] Recently, a case of commercially marketed amateur radio equipment operating in the 2 meter band caused harmful interference to a radio navigation system used by aircraft. It was found that the equipment was generating spurious emissions which were disrupting operations of this source of interference required investigation by the Commission, in addition to assistance from the amateur operators. The operators involved cooperated by ceasing operation until the equipment problem was corrected. It is anticipated that such situations will be minimized by requiring the equipment suppliers to demonstrate to the Commission the capability of their equipment to comply with the appropriate technical standards before they are permitted to market it to the amateur community.

equipment is designed and built to very high standards. Equipments of many manufacturers have undergone extensive testing in the League's well-equipped laboratory before advertising has been accepted for *QST* or before descriptions of equipments have been reported in *QST*. As far as the League has been able to ascertain, every manufacturer of receivers, transmitters, transceivers, and external amplifiers either owns modern up-to-date test equipment including spectrum analyzers, or has access to such equipment through contract with a qualified laboratory. Spurious radiations, if they do occur, are more likely to result from malfunctioning of some component than from any deficiency in design. The single example in footnote 6 of interference from spurious emissions from an amateur station illustrates the effectiveness of amateur cooperation in eliminating interference conditions. Have not the manufacturers learned a lesson from that incident? Are dozens of manufacturers to be ensnared in government red tape because of a single incident involving a single manufacturer? How could the higher prices which would be required be of benefit to the individual amateurs? The answer is obvious. One instance of unsatisfactory equipment does not establish a need for type acceptance of all equipment.

The League is not opposed to type acceptance if there is a real need for it. It does oppose the instant proposal, however, both because it knows of no substantial need and because the real purpose is to achieve control over the design of equipment in an effort to prevent its use in the 27 MHz CB band. There is no way even to estimate at this time the effect type acceptance and the modifications required to prevent a "change in the equipment's operating characteristics" (Notice, para. 4) which the Commission may impose, would have on the basic design and construction, the adaptability for operation on other frequencies such as those of MARS and those which may be added by the 1979 WARC, ease of servicing, and cost to the amateur.

Unless and until a more persuasive showing is made that type acceptance, as proposed in this proceeding, would not have an adverse impact upon the Amateur Radio Service and its equipment, the League must oppose the proposal.

VI
The Proposed Limits On Spurious Emissions And Radiations Are Unnecessarily Severe

As recently as March 2, 1977, the Commission amended Section 97.73 of its Rules to establish the following limits on spurious emissions:

> §97.73 *Purity of emissions.*
>
> (a) The mean power of any spurious emission or radiation from any amateur transmitter or external radio frequency power amplifier being operated with a carrier frequency below 30 MHz shall be at least 40 decibels below the mean power of the fundamental without exceeding the power of 50 milliwatts. For equipment of mean power less than 5 Watts, the attenuation shall be at least 30 decibels.
>
> (b) The mean power of any spurious emission or radiation from any amateur transmitter or external radio frequency power amplifier being operated with a carrier frequency above 50 MHz but below 235 MHz shall be at least 60 decibels below the mean power of the fundamental. For transmitters having mean power of 25 Watts or less, the mean power of any spurious radiation supplied to the antenna transmission line shall be at least 40 decibels below the mean power of the fundamental without exceeding the power of 25 microwatts, but, in any event, need not be reduced below the power of 10 microwatts.
>
> (c) Spurious emission or radiation from an amateur transmitter or external radio frequency power amplifier being operated with a carrier frequency above 235 MHz shall be reduced or eliminated in accordance with good engineering practice.

The Commission now proposes even stricter limits for type acceptance. After stating in paragraph 6 that, while the limits of Section 97.73

> may be adequate for equipment used by the individual amateur, we propose to require a 43 + 10 log (mean power in Watts) decibel suppression for type acceptance purposes, inasmuch as such equipment may be available in large quantities and thus, in the aggregate, will have a greater potential for interference. This degree of attenuation was chosen to correspond to the requirements for the land mobile and broadcast services.

It is respectfully submitted that there is no sound basis for suppressing spurious emissions of amateur equipment beyond those set forth in Section 97.73. Unlike transmitters in the land mobile and broadcast services which are designed to operate on one or a limited number of discrete frequencies, most amateur HF transmitters, transceivers, and amplifiers are designed to operate on any frequency within five amateur bands between 3.5 and 29.7 MHz, and some equipments are designed to operate in the MF 1.8 MHz band as well as four or five HF bands. The design of equipment operating over such a wide range of frequencies is much more difficult than for equipment operating on fixed frequencies. In addition, should spurious emissions occur, they probably would fall within the amateur band and not cause interference to any other service. Any potentially objectional spurious emission probably would be a harmonic and, because of the harmonic relationship of the amateur bands, might very well fall within an amateur band. Finally, when complaints of interference are received, whether because of spurious emissions, overloading of the complainant's receiver, or other causes, the amateur invariably installs a low pass filter in the output of his transmitter which attenuates all harmonic emissions above the designed cutoff frequency by at least 60 dB and often more than 80 dB. The end result is that there is only a very slight possibility of spurious emissions from an amateur station even without the limits of Section 97.73.

One other concern must be expressed. The building of amateur equipment from kits supplied by several manufacturers is an extremely important aspect of amateur radio. Not only does the kit builder often obtain high quality equipment at a price lower than that of manufactured equipment, but also he improves his technical knowledge and learns to service his equipment should malfunctioning occur.

Under the circumstances, it is respectfully submitted that no need has been shown and none exists for increasing the spurious emission limits for type acceptance beyond those specified in Section 97.73.

VII
Interference From Operation In The Amateur 10 Meter Band Has Not Been A Problem

In a further effort to justify its type acceptance proposal, the Commission states as follows:

> 7. Traditionally, the amateur operators have been in the forefront in developing techniques for solving interference problems, both through the use of external filtering and through actual modification of the transmitting equipment. This, in addition to the lesser degree of proliferation of equipment as compared to transmitters in the Citizens Band Radio Service, is our reason for not requiring the attenuation level of these transmitters to be as great as for the CB band. However, it may be necessary in a future rule making proceeding to readdress this matter if frequent problems from interference occur. Of immediate concern is operation in the 10 meter band. A Notice of Inquiry and Proposed Rule Making in Docket 21000 released November 30, 1976, addressed the matter of requiring 100 decibels of attenuation for spurious and harmonic emissions generated from transmitters in the Citizens Band Radio Service. Any actions taken in Docket 21000 may be reflected in our actions in this proceeding. Therefore, the attenuation level of spurious and harmonic emissions for transmitters operating in the 10 meter band may be made equivalent to any attenuation levels which may be adopted in Docket 21000.

Presumably, the Commission is referring to television interference.

The number of complaints of television interference from amateur operations in the 28.0-29.7 MHz band has been commensurate with complaints from operation in lower frequency amateur bands. The techniques referred to in paragraph 7 of the notice consist of installation of low pass filters between the output of the transmitters and the input to the antennas, and, at times, a high pass filter between the television receiving antenna and the input to the tuner of the receiver. Occasionally, additional shielding and/or grounding has been necessary.

To equate amateur 10 meter operation with the 27 MHz CB service is unfair in the extreme. A CB operator is not required to have any knowledge whatsoever of radio theory. All that is required is enough money to buy a transceiver, an antenna, and a transmission line, and file a simple application for license with this Commission. As noted by Chairman Richard E. Wiley when he reluctantly concurred in the issuance of the instant Notice of Proposed Rule Making:

> My concern is that, in attempting to deal with the rapidly proliferating and sometimes troublesome CB service, we may appear to be penalizing the amateur community which, in my judgment, is one of the most "professional" and self-regulated services within the Commission's jurisdiction.
>
> * * *
>
> I look forward to a healthy and vigorous discussion on the proceedings which the Commission has opened today. Whatever their ultimate outcome, I wish to take this opportunity to express my respect and admiration for the amateur community. I hope and trust my colleagues will give these dockets, and the comments filed by the amateur community (as well as others), careful attention prior to reaching any final conclusion.

Should the Commission find it desirable or necessary to apply even more rigid standards on equipment capable of operation in the amateur 28 MHz (10 meter) band, a further notice of proposed rule making would be appropriate and is requested.

VIII
It Is Not Clear If Existing Manufactured Equipment Would Be "Grandfathered"

It is not clear from the Notice if manufactured equipment now in the possession of amateurs would be granted "grandfather rights" to permit the continued use and unrestricted sale of such equipment. The following appears in the Notice:

> 8. We wish to stress that although *we propose to require the use of type accepted equipment at stations in the ARS*, we have made specific exemptions for equipment constructed or modified by individual amateurs for use at a licensed station in the ARS. While manufacturers would be prohibited from marketing equipment prior to the receipt of a grant of type acceptance, the individual amateur would be permitted to construct his own equipment or to modify his equipment, whether home built or commercially procured, provided the modified equipment was for use at a licensed amateur station. In addition, the amateur would be permitted to sell his home built or modified equipment to another amateur. However, the amateur operator who decides to build or modify equipment in quantity for sale to other amateurs will be considered a manufacturer and will be subject to the type acceptance requirement. We feel that this will place the minimum burden upon the individual amateur radio licensee and will still encourage the experimentation and testing of equipment which, in the past, has been a major characteristic of the amateur community. (Emphasis supplied.)

Any changes in the rules obsoleting equipment would impose a very heavy financial burden upon amateurs. Unlike commercial users of radio, amateurs cannot amortize for tax purposes the cost of their equipment.

The Notice leaves unanswered several important questions. Must an amateur modify his manufactured equipment in some manner to continue to use it or to sell it? A similar ambiguity in the Notice of Proposed Rule Making and in the First Report and Order in Docket 20777 led to the filing of several petitions for reconsideration and brought about clarifying amendments to the rules adopted by the First Report.

Should the substance of the rules proposed in this proceeding be adopted, the League urges that the lessons learned in Docket 20777 be applied here, and that the report and order as well as the rules specifically provide that all equipment now owned by amateurs be exempt. The League also recommends that ample lead time be provided before any new or amended rules become effective to enable manufacturers to set up new production lines and distributors and dealers to sell equipment now in the distribution system.

IX
What Has Happened To The Commission's Program of Deregulation?

Under the leadership of Chairman Wiley, the Commission embarked upon a program of deregulation four years ago. Insofar as the amateur service is concerned, a few deregulation actions were taken, followed shortly thereafter by more restrictions under the guise of deregulation. Now, in a number of proposals including Dockets 21000, 21116, and 21117, all pretense of deregulation has been abandoned.

The League is constrained to ask, "What has happened to the Commission's program of deregulation of the Amateur Radio Service which almost every Commissioner for the last 40 years has praised for its self-regulation?"

X
Amateurs Are Cognizant of And Deeply Concerned About The Illegal High Power Operations In And Adjacent To The 27 MHz CB Band

In the almost 20 years since the Class D 27 MHz CB service was established, literally thousands of amateurs have expressed to the Commission and to members of Congress their concern about the excesses in 27 MHz operations by both licensed and unlicensed stations. Particularly since the growth of the 27 MHz CB service exploded two years ago, amateurs have been unjustly blamed for television and other interference actually caused by high power operation of 27 MHz CB equipment in violation of the rules, with the result that countless municipalities have adopted ordinances severely restricting the use of outdoor antennas by amateurs.

The League's objection to the proposals of this proceeding and to those of Dockets 20282, 20777, and 21116 should not be construed as a lack of awareness of the extremely serious problem of illegal CB type operations facing the Commission?[7] The League is most desirous of assisting the Commission in finding a solution to the dilemma, but it cannot sit idly by while the Commission proposes regulation after regulation which will have the cumulative effect of emasculating the amateur service.

XI
The Feasibility Of Prohibiting Sale Of Amateur Equipment To

[7] It is respectfully submitted that the critical comments in paragraph 3 of the Notice are not warranted. The method to be used for determining power of an amateur transmitter is unrelated to the instant proposal.

Other Than Licensed Amateurs Should Be Explored

Chairman Wiley concurred with considerable reluctance to the issuance of the Notice in this proceeding, and expressed the hope "that the comments we receive will suggest other and better alternatives to the Commission's proposals" and, at the same time, "recognize the tremendous task facing the FCC in regulating CB radio which, in the space of only 2 years, has grown from 50,000 license applications a month to over one million applications in January, 1977, alone."

As long ago as 1971, the League suggested in comments filed in opposition to RM-1747 and in opposition to the proposal for a Class E CB service in the 220 MHz amateur band (Docket 19759) that the Commission consider prohibiting sale of amateur equipment to other than licensed amateur operators and requiring the registration of serially numbered equipment. Similar suggestions have been received from other amateurs over the years. A few dealers in amateur equipment have adopted a policy and practice of refusing to sell to non-amateurs. Most unfortunately, it appears that voluntary compliance with such a policy on a large scale cannot be achieved.

Two petitions for rule making proposing rules to permit the sale of amateur type equipment only to licensed amateurs now are before the Commission awaiting action: RM-2839, filed by the San Antonio Repeater Association on February 9, 1977, and RM-2866, filed by Frank W. Napurano, licensee of Amateur Radio Station K2OKA, on March 24, 1977. The R. L. Drake Co. has filed *comments in* response to RM-2839 which set forth a comprehensive and detailed plan to provide such controls. Numerous comments in response to the Nótice in this proceeding suggest similar controls. Some of the respondents also have suggested that all amplifiers and transceivers bear permanently affixed serial numbers and a central registration office be established to aid in enforcement activities.

Although the League has considered the feasibility of prohibiting the sale of external radio frequency amplifiers, transmitters, and transceivers to persons not holding a valid amateur license, it has serious doubts as to the statutory authority of the Commission to adopt such rules and practices.

The League strongly recommends that the Commission process with high priority the two petitions, RM-2839 and RM-2866, and either issue a notice of inquiry and notice of proposed rule making or deny the petitions with a statement of the reasons for the action. Should a denial of the petitions be based upon lack of statutory authority to adopt and enforce any such rules, requests for appropriate legislation then can be presented to the Congress.

XII
Effective Enforcement Of The Present Rules Is The Only Solution To The Problem Of Illegal Operations

The Commission has been aware of the widespread misuse of the 27 MHz CB and adjacent channels by unlicensed stations and by stations operating with powers in excess of that permitted by its rules since shortly after the Class D Citizens Radio Service was established in 1958. The Commission's requests to Congress for legislation granting it authority over unlicensed stations and equipments have gone unanswered for several years. Requests for funds to mount an effective areawide or nationwide enforcement program have been unproductive. The Commission is the laughingstock of millions of licensed as well as unlicensed 27 MHz CB operators. The chances of a CBer being apprehended for unlawful operation are far less than a motorist being apprehended for violation of the national 55 mile per hour speed limit in a state where only token enforcement is practiced.

Amateur radio operators have expressed their concern over the ever increasing unlawful operations in and close to the 27 MHz band over the years, and their fear that CBers may overrun the amateur bands. "Intruders" already have appeared in the amateur bands, some using amateur callsigns either assigned to others or unassigned, and some operating only with pseudonyms or "handles" or phony callsigns.

Effective enforcement is the only solution. Millions of CB operators are losing respect for law and order because of the lack of enforcement of the rules and the excesses on the CB band. *The Commission must find some way to impress upon the Office of Management and Budget and upon Congress the need for funds to mount an effective enforcement program.* Any such program should be directed not so much against the individual operator who may violate relatively minor rules, but against the flagrant individual violators, manufacturers, and sellers of the high power equipment, both transceivers and external amplifiers, used for such unlawful purposes. Perhaps legislation granting the Commission additional enforcement powers also is necessary. *But one thing is certain: Adoption of unnecessary and unenforceable rules such as those proposed here will simply make matters worse and make even more difficult, if not impossible, the adoption of corrective measures in the future.*

XIII
Conclusions

The League well understands the demands of constituents to their representatives in Congress "to do something to clean up the CB mess" which interferes with their television reception, the urgings by members of Congress that the Commission take some affirmative action, and the pressures upon the Commission's staff to come forward with some solutions. The League and the entire Amateur Radio Service are just as desirous of finding a solution to the CB mess as is the Commission.

Amateurs, because of their technical training and practical experience acquired under the Commission's comprehensive and effective programs and policies, are uniquely qualified to evaluate the effectiveness of proposals intended to find at least a partial solution to the troublesome CB problems. The comments of the League and numerous individual amateurs opposing the proposals in this proceeding and the companion proceeding in Docket 21116 should be considered as being constructive. The Commission's hope that adoption of the proposals in these two proceedings will be effective has been misplaced.

If even one lesson has been learned from this proceeding and from the basic 27 MHz CB problem, it is that a personal radio service such as the 27 MHz CB service must never again be placed on frequencies in close proximity to amateur frequencies. The other lesson has been that the relationship to television broadcast channels must be considered when assignments are made in the future.

The Commission must recognize that, even should a type acceptance program for amateur equipment be successful, there are other techniques available which will permit continued operation with high power in and close to the 27 MHz CB band.

In conclusion, the Commission is urged to not adopt the proposals of this proceeding but, in cooperation with other interested parties, develop a more realistic program which will have some chance of success.

Respectfully submitted,
THE AMERICAN RADIO RELAY LEAGUE, INCORPORATED
Robert M. Booth, Jr.
General Counsel

VHF Special – Super COR – Digital of Course!, Touchtone Decoder – Using a Calculator Readout, Simple Amateur TV Transmitter, Amateur TV Receiving System, Mobile Autodialer, Autocall '76 – Using a Touchtone Decoder, Build The Lab Type Bridge – and Measure Transformer Impedances, How Those Triangle Things Work – a Sort of Op Amp Handbook, Those Exciting Memory Chips – RAMs, ROMs, PROMs, etc., ASCII/Baudot with a PROM – for Ribbonless RTTY on Computers, Aim Your Beam Right – With a Programmable Calculator

JUL 76. Perfect CW – Drive 'em Crazy with the Keycoder I, The Mini-Mite Allband QRP Rig – A Mighty 7 Watts, A Fun Counter Project – Under $50, Build a FAX from Scratch – Then Get Satellite Pictures and Other Things, Dev Repeatermeter – Repeater Control with ID, The Giant Nixie Clock, Creative SSTV Programming, CW Regenerator/Processor, What's Up on 156 MHz?, TT Pad for the Wilson HT, Power Supply Testing – To Save Your Digital Circuits, A RTTY/Computer Display Unit, Your Computer Can Talk Morse, Gain for Your HT – a Half Wave Whip, The Super Transmatch, Simple VHF Monitor.

AUG 76. How Do You Use ICs? – Fundamentals, Surprising Miniature Low Band Antenna – the DDRR (Part I), MINI-MOS – the Best Keyer Yet?, The Skinflint's Delight Breadboard – Cheap Imitation of a Commercial IC DIP Board, More PLL Magic, The Logic Grabber – Selected Interval Logic Tracer, Global Calculations for the DXer – Using a Hand Calculator, Instant Counter Calibration – Using Your TV Set, Simple 450 MHz Rig – Go ATV With a $42.50 Module, The First Computer Controlled Ham Station – Grand Prize Winner, The Which Chip Dilemma! – 4, 8, 12, or 16 bits: pros and cons, Meaningful Conversations with your Computer – What All Those Mysterious Languages Are All About, A Baudot Monitor/Editor System, A Logic Probe You Can Hear, Satellite Orbit Predicting – Using a Pocket Calculator, FSK with the SB-401, Build the Safari RTTY Terminal, El Cheapo Signal Tracer – Test Gear for the Cheapskate.

SEP 76. The Surprising DDRR Low Noise Antenna (part II), Ultrasimple Regulation with New IC – Power Supply Design Greatly Simplified, Can an Indoor Antenna Work – Making the Best Out of a Bad Bargain, Inexpensive 12 Volts for Your Base Station, A Test Lab Bonanza – Using a Transistor Radio, Protect Your VHF Converter – Novel Antenna Relay, Ridiculously Simple RTTY System, How to Catch a CBer, A 450 MHz Transceiver for Under $130, Space Age Junque II, PROM Memory Revisited, Eight Trace Scope Adapter, The PROM Zapper, Sneaky Baudot – With an ASCII Keyboard!, Simple Graphics Terminal – Using surplus, Counters are Not Magic – They're Simple

OCT 76. Build a Weird 2 Band Mobile Antenna, Build a Counter for Your Receiver, How do You Use ICs? (part III), QRP Fun on 40 and 80 – Have a Real Ball with Just 5 Watts, The Hybrid Quad – Low Windload, Expense, Hassle!, Frequency Detector for Your Counter, Programmable CW ID Unit – for RTTY, Repeaters, Mobile, etc., New ICs for the Counter Culture – Simpler Counters with Less Used Power, Is My Rig Working or Not? – Build an Effective Radiated Field Meter and Know!, Quickie Collinears for 15 and 10 – a Satisfaction Guaranteed, Build a Super Standard – Goes Right Down to 1 Hz, The Incredible Lambda Diode, Mechanical RTTY Buffer, Have You Used a Triac Yet?, How to Interface a Clock Chip – Baudot, BCD, or ASCII Conversion, A TTL Tester – Great for Unmarked Bargain ICs, The New Ham Programmer – Making Those Confounded uPs Work, BASIC? What's That? – the Basics of BASIC, The Soft Art of Programming (part I).

NOV 76. Blockbuster 288 pg issue! Cordless Iron Tips, Bicycle Mobile, Build a Simple Lab Scope – Costs Less Than $20!, Get on Six with Surplus – The El Cheapo RT-70 is a Natural, The Beam Saver – Rotor Memory System, Updated Universal Frequency Generator, The Short Pocket Touchtone, Liquid Crystal Display Guide, Self-Powered Mike Preamp, The Wind Counter, The S38 is Not Dead!, The Amazing Inverted L – Antenna for 20, 40, and 80m, Battery Chargers Exposed, How Do You Use ICs (part III), Thirty Years of Ham RTTY, Big Noise Burglar Alarm, Dandy Digital Dial Decoder, Weather Satellite Display Control, Ham Time-Sharing is Here for You!, The Soft Art of Programming (part II), OSCAR Orbits on Your Altair, ASCII/Baudot Converter for Your TVT, The Smoke Tester – Power Supply Tester, The Man Who Invented AC – Tesla, the Greatest Pioneer of Them All!, Baudot to ASCII – You Want to Learn Programming?, Baudot and BASIC – an Interpreter for a Baudot Computer, Toward a More Perfect Touchtone Decoder, Using a Wireless Broadcaster, The Quiet Spy – Amateur Unknown Spy Ring in the US!, The Benefits of Sidetone Monitoring – And How to Do It.

DEC 76. Go Tone for Ten – Simple Subaudible Encoder, World's Simplest Five Band Receiver?, How Do You Use ICs? (part IV), A Super Cheapo CW IDer, The ZF Special Antenna, CT7001 Clock-buster, Saving a CBer, A Ham's Computer, What's All This LSI Bunk? – an Ostrich's Eye View of the Microprocessor, The Soft Art of Programming (part III), Put Snap into Your SSTV Pictures – Using a $20 Frequency Standard, What's all This Wire-Wrap Stuff? – Talk About Cold Solder Joints!, Exploding the Power Myth, Exploding the SWR Myth, The IC-22 Walkie – Portabilization with Nicads, Watch DX with a Spectrum Analyzer, DXing with a Weather Map.

HOLIDAY 76. 55 article issue! An Inexpensive 400 Watt HF amplifier, How Do You Use ICs? (part V), Mobile Smokey Detector – 10.5 GHz: Use It or Lose It!, Add RIT to Your Transceiver, DXpedition: Memories for a Lifetime – Reflections of HK1TL, Design Your Own QRP Dummy Load, Failsafe Super Charger – Multi-rate tool, The Amazing 18" Antenna for 160m, Replacing the Knife Switch – Simple TR System for the Novice, Now You Can Synthesize – the VHF Engineering Approach to 2m Happiness, Hutchinson's Remedy – the Chirpless CW Machine, The Mod Squad Does the Pocket Scanner – Radio Shack Pro-4 Update, TR-22 Mod Squad, What Computers Can and Can't Do, A Ham Shack File Handler – Program in BASIC for QSLs, Repeaters, etc., Print Your Own Logbook – On Your Nearest Computer, Showing Your HT, Cash In on the CB – Installation for Fun and Profit, Tuning Those Big Antenna Coils, The 2m Mod Squad Tackles the Weather Radio – and Wins!, Hamming by Laser, A 60 Foot Antenna on a 20 Foot Lot – Solving a 40m Novice problem, Dual Voltage Power Supply, An Autopatch Busy Signal, Inside the GLB – a Gutsy Look at a Synthesizer, How to Bug an Automatic Keyer, A 450 Duplexer – That Fits in Your Car, Will Silver-Zinc Replace the Nicad?

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

CAN THE QCWA SAVE AMATEUR RADIO?

The Quarter Century Wireless Association (QCWA) has been around for a long time, but has had little impact on events. As an editor of a ham magazine, I've been getting a little newsletter from the QCWA for years. It dwelt mostly on the departed and the departing, so I had an impression of the club as one of retired old-timers who were doing little more than waiting to die.

When my 25th anniversary as a ham arrived, I gave little consideration to joining the QCWA, not yet being ready to consider myself an old man. Eventually a good friend of mine, Harry Gartsman W6ATC, got rather involved with the club, so along about my 35th hamming year, I joined. Nothing came of it.

For some obscure reason, the QCWA invited me to give the talk at their yearly banquet — held in Seattle, during the ARRL convention. The League was pretty upset about this, but since it was not their banquet, they couldn't stop it. Mary Lewis, one of the organizers of the convention, asked me to speak to a couple of the convention groups — one on microcomputers and the other on hamming, for which blasphemy the ARRL appears to be making every possible effort to block her appointment as SCM. Petty politics, but routine.

Just judging from the QCWA newsletters, I'd gotten the impression that most members were old ARRL stalwarts, now living on social security and still afraid of trying anything new or experimental. I'd tried speaking to several ham clubs which were controlled by this type of old-timer, only to find that the minds were so tightly closed that there was no way for a new thought to penetrate. These are the musty ham clubs where you find virtually no new hams — no youngsters — and heaven help the CBer that wanders in for a meeting!

Not being willing to give up without a fight, when it came my time to speak at the banquet, I decided to find out who and what the QCWA was really made up of. I asked for a showing of hands of those present who had pioneered FM back before WW II (el biggo). Much to my surprise and pleasure, about fifteen hands went up. Hmmm.

Next I asked how many had helped pioneer narrow band FM in the late 40s, and again a bunch of hands went up. I was more impressed.

My critical question — how many were active on RTTY before 1950 — these had to be hard core pioneers. About 30 hands went up around the room. Very impressive for a group of about 500.

Well, okay for the long past, but what have they done for us recently? I asked about sideband pioneering and almost a third of the people in the room had been active on SSB before 1957. How about SSTV? Again, up went the hands! About 20 of them had been involved with moonbounce work and at least 50 were active on OSCAR. These were not just ordinary old men; these were the men whose pioneering has made amateur radio what it is today.

AMATEUR RADIO NEEDS LEADERSHIP

Readers keep getting exasperated with me for talking down the ARRL. I wish that these people would try for a moment to suspend blind belief in what they read in *QST* and talk with some of the old-timers who pioneered the hobby we have today and find out the true place the ARRL holds in history. It is not a nice one.

For instance, right now I doubt if you would be able to find one amateur anywhere in the world with any real grasp of the WARC situation who would take a bet that we will come out with even one ham band below 50 MHz. Yet you see little of this in *QST* and you hear nothing about it during the ARRL forums at conventions.

This is a complicated story, but it is one of which you should be aware, for this will have a profound effect on your hamming in a few years.

The QCWA members, far from being a bunch of withering old men, turned out to be representative of the very heart and spirit of amateur radio. These are the people who made amateur radio what it is today — the ones who pioneered and invented the circuits which we and all of the commercials are using. And they did all this with little help from either the FCC or the ARRL. Perhaps this group could do the job which the ARRL is not doing and help us to save our ham bands.

Before I explain the situation in detail, I should give some of my own background.

MY CREDENTIALS

Old-timers know me pretty well. Newcomers to amateur radio may not, so I'll take this opportunity to introduce myself. I should do this at least once every ten years anyway, and it is now about ten years overdue.

I first got attracted to amateur radio in the mid-30s, building my own shortwave radios along in 1936 and getting seriously into hamming by 1937. I started subscribing to *QST* in 1938, and have been a member of the ARRL ever since. That'll be 40 years next year. In 1941, I was quite active, mostly on 160m, and I even managed to win the ARRL Sweepstakes contest for my section that year, working entirely on 160m.

When the war came along, I enlisted in the Navy and went to radio and radar school, an experience which had a profound effect on me. The Navy school was splendid and made my later college work insignificant by comparison. I served on a submarine (*USS Drum SS228*) and went on five war patrols. For those of the readers who are particularly interested in submarines, I've been publishing a *Drum* newsletter which records the reminiscences of the crew, complete with a lot of 30-year-old pictures. I took a lot of pictures at the time and still have them all. We were one of the top scoring subs, by the way.

After the war and after college, I went into radio broadcasting as an engineer-announcer, then into television, first as an engineer and then as a director and producer. The TV work didn't turn out to be as creative as I'd hoped, so I left it and got into hi-fi, putting a speaker cabinet on the market in 1952, back in the early days of high fidelity. That business did very well, but when the chance came along to edit *CQ*, I picked that . . . wouldn't you?

Along in 1946, I got involved with the first narrow band FM experiments. I built several transmitters using NFM and had a lot of fun with it during those years. NFM would be with us today on the low bands if receiver manufacturers had built FM discriminators into their ham receivers. Using the slope of the i-f for NFM detection worked fairly well, but AM signals wiped out the FM, so NFM never really made it on HF. It was just the ticket for VHF though, and here FM detectors were being used — about 95% of the VHF and UHF communications today is by NFM.

About this same time, I got involved with RTTY. In 1948, I was working with WPIX (TV) in New York and had my 2m ham station set up on top of the News Building next to the WPIX transmitter. I was using a 522 (I had the first of them) and worked out all over the place from

LETTERS

HOOKED!

Way back in Oct., 1960, I subscribed to a new magazine which I found I enjoyed immensely. I didn't always agree with you, but I always enjoyed you. However, after about seven or eight years, I found that my interest in ham radio in general had waned and I let my subscription lapse. I have done just enough operating to keep my license current, but that's all.

Then, a couple of months ago, there arrived in the mail an announcement about a new magazine (where did you ever get my name?). It sounded interesting, especially with the name Green on the masthead, so I subscribed. Wow, hooked! This whole business of microprocessors sounded fantastic. So, I went out and bought an Intel evaluation board as one way to get started in this thing. In the process, the proprietor of the Byte Shop where I bought the board threw in a few recent issues of *73*. You know, it's even better than I remembered. So, enclosed is my check for another subscription. You have rewhetted my appetite for ham radio. I am looking forward to amalgamating these interests. Don't let anyone talk you out of continuing the I/O articles in *73* — it's obviously the future of the hobby, just like SSB was back in the 50s and repeaters have been recently.

Dr. Jerrold Goldman WB6MOE
Milbrae CA

STANDARDS

I just got done reading your last issue of *73* and I must say I enjoyed it very much, as usual. But there are a couple of things I would like to get off my chest.

First, I must say that I *was* a CBer, but after much frustration, I decided that there had to be something better in life, so I went to work on my ham ticket, code and all. And sure enough, it paid off when I worked WB6TVX — no great amount of DX, but I was a ham and very proud of it. I hope we will fight to keep our standards high enough to be proud of our licenses. They weren't just given to us — we had to earn them, and for some of us, it took a lot of work. Needless to say, it's something I value very much.

Hopefully, any CBer who wants to upgrade will take on the responsibility that comes with a ham ticket — that means code and all.

Also, as far as the I/O section and the computer articles, I don't understand much of it now, but I didn't even understand a simple amplifier circuit when I started. I am excited about the possibilities of computers in ham radio; it's a very high goal and a big challenge for me, but it's not impossible.

So, keep up the good work; it's a worthy cause.

Eugene Morgan WB7RLX
Ogden UT

COSMAC

To all 1802 users: *The 1802 Exchange*.

Very little software for the RCA CDP1802 is currently in the public domain. To remedy this situation, I am going to publish a ten-page booklet listing available software. If you desire to sell or even give away your software, please send me a listing for my review. My booklet will provide a complete description and cost information with a reference number corresponding to a number on an ordering coupon.

I plan to charge $1 for the booklet. This amount will also cover the costs associated with processing the coupons. The use of the coupon will reduce the costs to the person ordering from more than one source.

The publication date is set for early December. Advance orders may be made at $1 per copy. Here is your chance to buy a good selection of software as well as sell some. Send all orders, software listings, and other correspondence to:

TSETSE NIT

Pardon me while I pick a nit.

I enjoyed Sam Kelly's article on Soviet test gear (Aug. 77), but spotted one miniscule error. I'm sure that this important bit of information will be of great importance to all of your readers.

The VOM discussed and pictured is not a U-4341. The designation is Ts-4341. Although that letter may look like our "U," it is not the same. Note that it is somewhat square and has a tail. Transliterated, the letter is called "tse." (For what it's worth, the Cyrillic "U" sound looks like our "Y" — but that's another story.)

Now, aren't you glad that I spotted that grievous error?

William F. Blinn
Worthington OH

Got it! Thanks, Bill. — J.M.

MORE 220

This is in response to the letter "220 — No Loss" from M.P. Lewton WA6PHR, appearing in the August issue of *73*. I am sure that Mr. Lewton has not taken the time to examine the problems involved with an adjacent (or shared) amateur/CB 220 MHz allocation. We now realize that the allocation of 11 meters to the Citizens Service was a mistake, if only because of the proximity of the desirable amateur frequencies and the availability of equipment which is obviously illegal for use by the CB licensee. I, for one, do not want any of the three 220 MHz repeaters in Columbus to be infested by the uncontrollable illegal use that would occur if a CBer merely had to buy a crystal to cross the line. Perhaps Mr. Lewton would propose a CB band at 148.0 MHz?

M.P. suggests that we could still use the frequencies with our CB licenses, so there would be no loss to us. If I wanted to operate as a CBer, I would be a CBer and not bother with the FCC examinations in the amateur service. I am an amateur, I have not found any reason that requires me to get a CB license, and I don't foresee any reason that would make a CB license necessary or desirable for me in the future. 220 MHz is ours now, and we are getting along quite well without undisciplined intrusion.

Concerning the suggested reduction in prices on 220 rigs due to the CB mass production — where have you been, M.P.? Look in *QST* for May, 1977, page 169. The Midland 13-509, one of the best available 220 rigs, sells for $149 from AES, and similar prices from other suppliers all over the country. The Clegg FM-76 is similarly priced. The prices, when compared to two meter rigs of similar quality, are so reasonable now that it is unreasonable to assume that the EIA manufacturers will make any effort to reduce the price of 220 CB rigs.

The matter of whether CB really needs (or more importantly, *deserves*) more frequency allocations is really irrelevant — 220 is currently used extensively in some areas by a disciplined, licensed service. 220 MHz activity is growing strongly in many areas of the country as 2 meters becomes more and more congested, and the promise is for increased development as a practical, logical alternative.

Add to this the objections of Canada and Mexico, the widely-held view of a 220 MHz CB band as a governmental reward to CBers for their excellent success in creating a bastion of garbage and illegal activities on 11 meters, and the reluctance of the FCC to place a CB service in a frequency range that would allow the use of available amateur amplifiers, and you find the finger pointing to 900 MHz as the only reasonable spot to stick any expanded CB service.

So, Mr. Lewton, I suggest you get in touch with some 220 group in your area and learn some of the facts concerning the current amateur 220 MHz band. Maybe we'll see you there soon — as an amateur, *not* as a CBer.

DOES NOT COMPUTE

Please relieve me of the duty of removing that big thick book from my tiny apartment size mailbox, and the obvious advertising it gives the neighbors when placed in the adjacent junk mail collection box.

The last straw was the "article" in Aug., '77, "When the Lights Go Out — prepare yourself." Please, prepare first, like a good scout. Also, jelly for sandwiches for five days? Jelly spoils when opened in hot humid climates. Why leave out good old peanut butter? It keeps without cooling, is very nourishing, and is politically expedient.

Amateur radio *as it used to be* is still my favorite hobby. I can still remember listening to Pitcairn Island on 20 meter AM on a single tube superrengenerative receiver. And the thrill of the very first xtal clear CW on a homemade two tube receiver. And listening to Tennessee and Kentucky on 5 meters, back in Wisconsin, on a June day in '39.

Try *that* on your doggone newfangled computers.

Roy A. McCarthy K6EAW
Anaheim CA

WELL DONE

Our congratulations to Stew Perry, "King of 160," on his thirty years in amateur radio. I was impressed with his station as pictured on the cover of your June issue, but he really should do something about the accuracy of his clocks!

Chuck LaPointe WD9DXF
Orland Park IL

THANKS

This letter is to express my sincere appreciation to you for publishing my letter in the August issue of *73*, in which I asked assistance in getting information on ham radio for the deaf.

The response was immediate and dramatic. Only this morning, Gene DeGroot from Randolph WI called me. He has accomplished some remarkable work in this field. His advice has saved me many hours of ground work. Moreover, he has put me in touch with some ham operators who are deaf . . . and some both deaf and blind.

I do not mean this as a criticism of *QST* or ARRL, but as a high compliment to you.

Over a period of 4 months, I wrote Mr. Baldwin *twice* requesting this

from page 4

that beautiful location. My 16 element beam didn't hurt either. It was one built by UHF Resonator, Bill Hoisington, who many years later would write a long series of articles for *73* and would move to Peterborough to be near the magazine.

By late '48 I was deeply into RTTY and helped John Williams W2BFD set up the first ham repeater in the country in the Municipal Building in New York in 1949. It lasted a few months and then the FCC closed it down. The FCC worked for years to do all it could to prevent amateurs from pioneering and inventing . . . and they are still at it, though things are getting better.

In 1951, I started a RTTY newsletter; this ran until 1955 when I became editor of *CQ*. It was during this period that I became aware of the heavy hand the ARRL had on amateur radio and the way they worked with the FCC to discourage amateur pioneering. A group of us worked for years to get RTTY permitted on the low bands, with the ARRL fighting us every inch of the way.

When I became editor of *CQ* in January, 1955, I began to really get the inside dope on what was going on in amateur radio, and the more I heard, the more disgusted I got with the ARRL. Having known Harry Dannals W2TUK for several years, I figured almost anyone would be better as a Hudson Division Director, so I backed another chap — who won. This chap in short order put the League into good financial shape, got rid of the old general manager, and had things running better than they had been in years.

73 STARTED

After leaving *CQ* in January, 1960, I tried my hand at working for an ad agency, and then decided it was time to see if I could get a new ham magazine started. The projected expense for starting a new magazine was about $500,000, so I didn't have a lot of luck getting investors — I couldn't find one. Oh, well — I decided to go ahead without money and do it anyway.

Before I got into editing and publishing *73*, I was doing reasonably well . . . I had two Porsches, a nice Chris Craft Express Cruiser, a plane, yearly trips to Europe, and my own Arabian horse. Starting a magazine is akin to taking vows of poverty when joining a religious order . . . except that you can get out of the religion. No more Porsches, yachts, planes, or horses . . . and darned few European trips. After 17 years, I've become accustomed to working 100 or so hours a week, and since I have virtually no private life whatever, I am sort of amused at even the concept of a "personal expense."

Mind you, I'm not beefing. I signed up for this when I started *73* . . . and I aggravated it when I started *Byte* and *Kilobaud* magazines. There is a degree of self-destructiveness involved, too. Obviously this will catch up with me one of these days and bam, silent keys. My long-range goals are to try to make the world a little better place. Through the magazines, I provide entertainment, education, and help people have a lot more fun. Since I have little interest in money other than as a necessity for getting things done, I'm an enigma to many people.

Enough of all that — the main subject at present is the future of amateur radio. I've participated in many of the developments of the past: working personally with NFM, RTTY, SSB, SSTV, moonbounce, repeaters, OSCAR, DXing, DXpeditioning, and so forth. There isn't much that's gone on in the last 40 years of amateur radio that I haven't

FOUR DIFFERENT KINDS?

When I am invited to talk to an amateur group, I often begin by asking a rather simple but *loaded* question: "How many different kinds of repeaters are there?" Usually, I get as a first response exactly what I expect. An amateur raises his hand and says, "Two: open and closed." Then someone in the back of the room will shout out: "You forgot autopatch!" Most of the time it stops there, and the discussion starts.

Southern California relay communication is steeped in areawide traditions, and out of this has come acceptance of four different categories of relay operation: open, closed, private, and the individually owned and operated, remotely-controlled amateur base station radio, more commonly known as a remote base. To complicate matters even further, these four categories of relay systems operate under one of two operational formats: basic and advanced. Let's cover the latter of these two designators first.

Until about a year and a half ago, very few people gave much consideration to operational format. A repeater was a repeater, and remote bases were those "things" that popped up on .94 once in a while and were usually heard on .46. However, as technology progressed, so did a need on the part of some to show their own individuality. Out of this grew the terminology, "advanced format" and "basic format."

How, though, does an "advanced format" system differ from one of "basic format"? Really, it's in the peripherals and the use a system is put to. In many ways, the microprocessor had a lot to do with it, I guess. Many "advanced format" systems utilize microprocessors for overall system control and security. Then there is the concept of interlinking on a wide scale basis. Some of these groups have intentions of building national interlinked networks, by which they will be able to "function up" any city they wish at the touch of a finger on a tone pad. Some are well on their way to achieving this goal. From the foregoing, you might imagine that most "advanced format" systems are also private systems. Your assumption would be correct. In fact, "super private" would be far better terminology. This type of advanced state-of-the-art communications requires a totally controlled environment, and it is for this reason that no such system is found on two meters. Those involved in "advanced format" amateur relay communications tend to go to spectrum where they can achieve their objectives without taking away valuable spectrum from the average ham. They "do their thing," bother no one, and (most important) help advance communications technology. If there is one point of consternation, it is that such systems are not available for use by the average "Joe Ham"; their basic structure precludes this. Sometimes a system such as this is "down" for months of redesign, and very few "users" are willing to put up with this. By and large, they are made up of small groups of a dozen or fewer dedicated experimenters, who seem to live for a "mission" of finding a better way to "do it," to talk farther. In actuality, the terms "advanced" and "basic" have come from those involved in the former, as a way of letting the world know that their particular operation is indeed different from the norm. Anything that does not meet the criteria of an "advanced format" system is then considered "basic format." Having an autopatch does not count.

Now, let's discuss categories of repeaters. We are talking "types" and not access coding. Open repeaters? Yes, we have our share of them. In fact, this state boasts more open repeaters than anywhere else in the nation. Want to involve yourself in emergency communications? Want to rag chew? No matter what you are looking for, there is a repeater somewhere to meet your needs, an open repeater, there for your use. Most licensees and/or sponsoring organizations only ask that you use and support such systems and not abuse them. Some have very lenient system regulations, while others might well constitute a structured mini-society. Whatever your preference, you will find it.

How, then, do "closed" and "private" systems differ from open systems and from each other, and, under the structure of FCC regulation, how can they exist? The latter answer is indeed simple. Justification for such systems comes from official recognition of their existence. Such was the case during the early days of deregulation, when, in its report and order on remote control, the FCC specifically recognized the concept of the closed system and granted such systems the ability to operate under the doctrine of "fully automatic remote control" (while at the same time granting only "semi-automatic remote control" to open systems). There are also the statements made by FCC personnel when questioned on this topic, such as that of Dick Everett at SAROC's FCC Forum last January, when he stated that no amateur is obligated to provide any service to any other amateur. Then, too, there is the question of the constitutional right of an individual to use his amateur station (his own personal property) in any way he sees fit, as long as its use does not bring harm to others.

Suffice it to say that the FCC and the overall amateur community have come to recognize the existence and operation of relay systems whose access is available only to a limited segment of the amateur community. I realize that to some the existence of such systems is a sore spot; however, the fact is that the concept of the "limited access system" is growing out here, and I suspect that we are indicative of what's happening nationally. You in your area know far better than I. By present count, southern California holds (on 2 meters) twenty such classified systems, up three from last year. 220, a band most thought would be a haven for open systems, is about 30% limited access. However, here such systems are forced to share channels with other such systems. So while there may be twenty SCRA-coordinated closed and private systems on 2, only part of that number of channel pairs is in use by them.

"Closed" systems differ from "private" systems in the following way. A "closed" repeater is one in which membership within the sponsoring organization is required in order to use said system; however, such membership is available to all interested members of the amateur community. Systems dedicated to emergency services, such as RACES and ARES, wherein all communication content must be of either an operational or "drill" nature, would probably be fair examples. On the other hand, a "private" repeater also requires group membership. However, membership and thereby system access is at the total discretion of the system licensee and/or his sponsoring organization. Therein lies the difference.

I'd like to dispel the long-standing myth among amateurs that a repeater is automatically to be considered "closed" or "private" if it requires that users equip themselves with tone coding devices to activate the system.

I call this a myth because that is exactly what it is. However, even such an austere organization as the ARRL seems to live under this total misapprehension, as was made evident in their July, 1977, issue of *QST* ("Washington Mailbox" column, p. 74), in which the writer states something to the effect that any repeater that requires a tone to activate it is a closed repeater. While placing a tone-activated device on a system's input can have the effect of limiting usership, such is not the proper use of such devices. Tone coding in its many forms, including burst, digital burst, CTCSS, and digital CTCSS, was developed for use in the commercial land mobile radio sector as a means of increasing spectrum loading — not to keep people off repeaters.

Here is how such a system works. Most commonly used in the land mobile service is CTCSS, which stands for Continuous Tone Coded Squelched System. You might be more familiar with it under one of its trade names, such as Motorola Private Line (PL) or General Electric Channel Guard. These are registered trademarks of these manufacturers. They enable more than one person to operate on a given channel (or channel pair, in the case of relay devices) on a minimal interfering basis. Such an entity might be a "community repeater," as we shall now describe.

Most of us consider a repeater to be a device with which one group of people communicates via a given channel pair. In commercial service, one repeater may be set up to serve the needs of two, three, or even a dozen individuals or business groups. This is accomplished by assigning individual tone code assignments to each person on the system. In our example, let's say that we have three businesses sharing a commercial repeater. Let's call them Smith's Delivery Service, Tom the Plumber, and City Bus Service. Each has a specific communications need, and CB radio will not suffice. They all wind up on a given "community repeater." Each is assigned a specific EIA standardized tone code of the CTCSS variety. Smith is assigned 1A, Tom gets 3B, and CBS gets 4B. However, all operate through the same repeater and transmit and receive on the same channel pair.

Contained within the electronics of both the repeater and each user's radio are tone encoders and decoders. The repeater itself has the ability to decode and regenerate all three of the CTCSS tones installed, while the users' radios only respond to their preassigned codes. Let's suppose that Mrs. Jones, the dispatcher for the bus company, wants to tell Tim, the driver, to go over to the Little Red Schoolhouse. She removes the microphone from its cradle. When she does this, a switch built into the cradle automatically closes and defeats the internal decoder, allowing her to hear any channel activity that's not being directed toward her. Hearing nothing, Mrs. Jones calls her mobile and passes her message. Had she heard another conversation in progress, she would have been obliged to wait for its conclusion. In the meantime, when no traffic is being directed at her, her radio is silent, even though the channel may be under heavy use. The same holds true for each of the channel users. They only hear traffic directed at them — unless they want to listen in for entertainment purposes. I suspect some do.

The ability to share, to increase channel loading, and thereby to use spectrum more efficiently, is the true purpose of tone coding. To use it to restrict those "unwanted" by you or your group is defeating its intent — tone coding was never meant to be a means for security, and besides, with tone codes EIA-standardized, how much and how effective a security method can it really be?

This being the case, what really makes a repeater "closed" or "private"? It's attitude, the attitude of those people placing such systems into operation and the attitude of those invited onto such systems. In our part of the country, we have a number of totally "open" systems which, due to either co-channel assignments or nearby adjacent channel assignments, have utilized tone coding as a method to minimize interference to their operation. Still, these systems are in every sense of the word "open"; they are available to any amateur who wants to use them. By the same

token, we have a few "private" repeaters that require no tone access whatsoever. Yet these systems are truly "private" in every sense of the word. In each case, it is the attitude of those involved with a given system that decides its category — tone coding enters not.

How can amateurs make better use of methods such as CTCSS? On an individual basis, it's been happening for years on WR6ABB and a few other LA area repeaters. Following the lead of the commercial sector, a number of individual sub-user groups have taken to installing CTCSS encoder/decoder packages in their radios, with automatic mike cradle switches as earlier described. In this way, they can still hear the messages directed toward them, even though they are not forced to listen to all the channel chatter. One might call this "private" groups functioning through "open" repeaters.

Another method is that of channel sharing in crowded urban areas, where coordinators have run out of available spectrum and are faced with an ever-mounting deluge of channel assignment requests. What I am about to describe may not now be popular, but wait four or five years and then read it again.

Suppose that an area is totally out of spectrum upon which to coordinate another repeater without causing massive interference to existing area activity. On the coordinator's desk sit 100 or more demands for repeater pairs. If he does not act soon, he may have a hundred or more pirate systems challenging existing activity. A hundred repeater wars. Then an idea hits him . . . CTCSS! "Why not?" he says to himself. "Why not assign all existing activity of open repeaters a given areawide CTCSS tone, and then assign a second tone and the necessity for a lockout receiver to all the next generation of repeaters — and then coordinate them atop one another?!" In essence, all existing systems would become primary channel activity, and any new system could only operate when existing activity of the initially coordinated system ceased. Now, it might not work for every channel pair, but it would be fine for those of low activity. In fact, you could possibly put six or seven per channel, with each assigned a different tone and each required to lock out when it heard any other tone of any system of an earlier coordination date.

Okay, there are obvious pitfalls to such a system. The largest is getting any group of hams to agree totally to anything. With ever-mounting pressure on urban area coordinators and councils, however, do not be too surprised to see something along these lines in the not-too-distant future. Note that many of the new radios coming to the marketplace have tone coding built in — or at least a provision for it. Do the manufacturers know something that the rest of us don't?

Let's finish this by putting this myth to rest forever. It is not tone coding that makes a repeater "closed" or "private," but rather the attitude of the people who own and use it. If tone coding has one asset, it is that of a "sign" or "symbol" that states to the rest of the world that it is for use by and for members only.

What about the fourth category, the aforementioned "individually owned and operated, remotely-controlled amateur base station radio"? How does it differ from a repeater, and why is there a rather phenomenal growth lately in the number of these systems? Statement of fact: A remote base is not a repeater. The only similarity lies in the hardware, and that is where the similarity ends. The root structure is "simplex ability using relay technique." Suppose you lived in a bad spot for direct station-to-station communications, but for some reason did not want to use a repeater to communicate. In fact, you wanted the total flexibility of your base station radio, with the added ability of long distance communication. You could relocate atop a mountain, but is it not better to just move your radio atop a mountain and then operate through it by remote control? In its purest form, that is exactly what a remote base is.

However, today's *modern remote* base is far and away a lot more than that. First, if you can put a two meter downlink radio on the hill, why not six, 220, or 10? Why not 160 through 10 on CW and/or SSB, as well? Why not an autopatch function? How about the ability to "swing" a tri-band beam or remotely tune in single kHz steps all of the low bands? Remember, unlike a repeater, whose licensee has a specific responsibility to a given usership, a remote base is technically individually owned. Therefore, the licensee can do things with it that might bring chaos to the average open repeater. With a remote rather than a repeater, the owner is totally free to experiment and operate to his heart's content — and never once worry about the responsibilities that an amateur running a repeater for a given usership has. I suspect that it is this overall total freedom that is responsible for the dramatic growth in such systems.

While by law an individual by himself must own a remote (in the eyes of the Commission), this does not mean that there's always one remote per ham. While a good number of single owner/user systems abound, at least an equal number are organized as closed membership amateur communications organizations. These organizations, usually numbering no more than ten individual amateurs, are very closely knit, and in virtually every case are made up of individuals of exceptional skill in the art of two-way VHF/UHF communications.

I said earlier that a remote is a "simplex" device using relay technique. Taking this further, most remotes come into being because an individual or group is interested in expanding their ability to talk without the aid of a repeater. They do not want the restrictions of "3-minute timers" and of having their QSOs interrupted every two minutes by breakers. They want the same ability from their mountain as they have from their home ham shack. By utilizing the concept of the remote base, they achieve their individual objective. At present, there are an estimated 300 or more such systems in this area alone; hardly a day goes by without running into someone who tells you that he is building one also. I might be wrong, but I would be willing to venture a guess and say that the modern remote base is possibly the fastest growing of all forms of amateur relay communications currently to be found out here.

THE GOOD GUY

While back east a while ago, one of my scheduled stops was at Clegg Communications in Lancaster, Pennsylvania, both to see Ed again and to do a "Manufacturer Profile" story for this magazine. It was about 90 miles to Lancaster from Valley Stream, Long Island, where I was staying, so early that particular morning I made a beeline into Brooklyn to pick up Larry Levy WA2INM, who was to act as my photographer. The two of us then headed toward Lancaster in my father-in-law's '73 T-Bird.

By five that afternoon, we were ready to head back to New York. We bid good-bye to Ed and his staff, and jumped back into the car. It started fine, but when we placed it into "drive," we found that it had decided that it liked Lancaster a lot and wanted to remain. The transmission had died — or so we thought. Not knowing exactly what to do, Larry and I ran back into Ed's office just as he was about to depart. We explained our plight, and in short order Ed had literally solved every problem for us.

First, he found us an auto mechanic who later turned out to be one of the most righteous individuals I have ever run into. Then, though he had a rather important dinner and meeting to make, he personally took the time to take us around and help us find transportation back to NYC, finally dropping us at the airport in Lancaster. We had hoped to make a commuter flight to Philadelphia and then grab either TWA or American back to JFK. As luck would have it, the commuter flight (which was the last one) was a sellout, but National Car Rental came through with an Olds Cutlass that got us back to the "Big Apple" in fine fashion by midnight.

If "LW" could give a "good samaritan" award, my first nomination would be Ed Clegg W3LOY. He did not have to go out of his way for us. Even though he had important appointments to keep, an act of human kindness to a friend he deemed more important. Both Larry and I probably will never find the proper words with which to say thanks. We both hope that this is a proper beginning. This being my first trip to the Lancaster area, I was quite at a loss when the situation arose; having someone extend a warm hand of friendship at that moment was very welcome indeed.

THE BIG LINK

What do repeater stations WR5AFS in Houston, Texas, and WR6AWQ in Los Angeles have in common? What event did repeater stations WR6AWS and WR6AAE also share in part? Answer: probably the record for the longest duration repeater interlink between two cities separated by over 1,000 miles. Would you believe three hours and forty-two minutes? Not that this record is important. More so is what happens after the initial shock of a two thousand mile link wears off.

I have been involved, in one way or another, in linking efforts before. In fact, one of the very first, between Waltham, Mass., and Los Angeles (about five years ago), was a direct result of an offer by one of our local repeater owners to try such an experiment that was printed in one of the earliest "LW" columns. Not long ago, we reported on Sam Davis WA1GQY/6 and his "Linking America," which at last report is still going fairly strong. However, most of the latter consisted of people at both ends exchanging callsigns, salutations, and requests for QSL cards.

WR6AWQ and WR5AFS are quite different from one another. WR5AFS is an open repeater located in Houston, with about 70 to 100 regular users. It is a two meter system, sponsored by an organization known as the Houston ECHO Society. WR6AWQ, on the other hand, is a private 220 MHz system that is itself part of an organization called Westlink, the objective of which is to organize a network of autonomous intertied repeaters to provide statewide communication. As I mentioned earlier in this column, a good number of such organizations exist. With the differences in operational category and format between the two, what would you imagine the outcome to be?

It was, for all participating, one of the most fascinating and educational evenings ever spent. After "initial shock," which lasted for about a half hour, one began to realize that QSO after QSO was taking place — meaningful QSOs, in which everything from system operation to things of a far more human nature were being discussed. It was a Sunday evening, and the Houston group had been involved in their weekly net as the link started. For part of the linkup, the Los Angeles AWQ group took part in a net in a city a couple of kilomiles away!

What happens, then, when you link two repeaters? People talk, and out of this gain a far better understanding of

their fellow man than they could when isolated by the coverage restrictions of an average repeater. Both systems are eager to do it again. If your system is interested in linking with either or both, drop me a note, and I'll act as a clearinghouse and pass it on to the proper party. WR5AFS and WR6AWQ may hold the current record for the longest repeater interlink, but I suspect that they also might account for the greatest number of new friendships evolving from amateur radio in one evening.

220 IS ALIVE, WELL, AND GROWING IN HOUSTON

According to Kent Marshall W5TXV, six months ago there were about ten intrepid souls in the Houston, Texas, area who were playing around on 220. What a difference a few months can make. At present, there are over fifty amateurs now on 220, and an experimental repeater is operating on the high .34/.94 pair, under the callsign WR5ATG. Kent credits this growth to two factors: the Clegg FM-76, and a gentleman named Doug Burns W5FUH, who is spearheading 220 growth. In Texas, as here in California and elsewhere, amateurs have come to like 220 because it is still uncrowded. Even via a repeater, one can hold a true conversation — a feat which is fast becoming impossible on two in many places. How long this will hold true is anyone's guess, since 220 seems to really be taking off. Here in southern California, the last of the available 220 pairs was recently coordinated, and now Tom Rutherford W6NUI and his SCRA 220 Technical Committee are involved in multiple co-channel coordinations. Nineteen such coordinations have already been made, with many more expected to follow.

In Texas, 220 is growing, and if what I hear about Texans is true, I suspect that 220 will get the "Big Texas Treatment" that has helped two to grow and prosper. Amateurs have headed the call of "220 — Use It Or Lose It!", and while we must never be complacent, I have a sneaky feeling that Class E CB would find it quite hard to manifest itself up there in quite a few places, contrary to what certain EIA-oriented information might say. Good work, Texas!

SOUTH CENTRAL U.S. MAY ADOPT CALIFORNIA TERTIARY PLAN

While no official announcement has been made as of this writing, according to informed sources the Texas VHF-FM Society, along with coordinating groups from Tennessee, Mississippi, Louisiana, Oklahoma, and New Mexico, will shortly announce formal adoption of the Modified SCRA Inverted Tertiary Plan for split-split repeaters. This would signify two things. First, that interest in VHF relay communications among amateurs continues to grow, and thus a need to expand the number of available channels has reached these areas of the nation. Second, it signifies that endorsement of this plan by the ARRL in a recent *QST* article on the subject (October, 1976, pp. 47, 48) has had a profound effect on its acceptance by the amateur community.

It is my sincerest hope that these areas have as much success with this plan as we have in southern California. The ARRL has stated that the best chance of technical success seems to come through this method, and I think our overall success during the past three years has shown this to be true. The SCRA still has available a technical paper written by Bob Thornberg WB6JPI on this subject, and an 8½ x 11 SASE with a bit of patience on your part will bring a copy. Send your request to SCRA, PO Box 2606, Culver City CA 90230. Though written three years ago, the concepts contained therein are as practical today as they were then. They are the basis for a good part of this area's successful coordination effort.

TSARC CARES

As you are already aware, in May I was back east. I happened to show up at just the right time. Well, to be truthful, I had been made aware beforehand by Dave Minot WA2EXP, TSARC chairman, that the Tri-State Amateur Repeater Council would be holding an open general membership meeting. Dave extended a personal invitation for me to attend and meet the group.

What intrigued me was a discussion underway when I arrived. It dealt with a matter very close to my heart: willful and malicious interference to amateur relay communications by the "sickies" of this world. Now, nothing new came of this discussion. What in my mind may be precedent-setting, though, is the fact that a repeater council had felt it was in the interest of all amateurs to involve themselves in some way in trying to solve this problem. Maybe for the first time ever, such a body was saying "we've had enough" and was beginning to turn their heads toward finding a way to take action. I personally wish them all the success in the world, and pledge to do anything in my power to aid them or anyone else so inclined.

Their structure is a bit different from that of the SCRA, and perhaps a bit of comparison is warranted. As you may be aware, the SCRA's chairman appoints two Technical Committee heads, one for two meters and one for 220, who in turn form technical committees whose makeup is representative of each geographic area administered by the parent organization. The committees discuss all coordination requests, evaluate them for technical merit and compatibility with existing activity, and assign or deny coordination by majority vote.

The TSARC, however, has an individual coordinator. He makes such decisions, based on the same criteria, and works with the organization proper on sort of an "advise and consent" basis. As I understand it, the overall responsibility for the implementation of his rulings rests with the council itself. The council also retains the prerogative to override the coordinator's decisions, request reevaluation, and/or implement a decision of its own.

Which system works better? It's hard to say. Each fits the overall needs of an area, and each has proven to be successful. Each has its own form of controls and restraints built in, and each affords representation to any and all systems that request and require such. As Dave said to me, "Duke Harrison has been doing such an overwhelmingly successful job that there is no reason to change things."

Everyone I met seemed satisfied with the structure of the TSARC and with the dedication that they have shown to that area's relay communications needs. They also care a lot about what's happening and where we are heading. If they were to adopt a motto, I guess it would be "Technical Competence With An Eye Toward Tomorrow."

10 METER NON-RELAY BAND PLANNING COUNCIL FORMED

According to Norm Lefcourt W6IRT, the large and continually growing number of amateurs in southern California who are converting CB radios to channelized 10 meter activity, after evaluating all of the band plans offered, have concluded that what they originated late last year is best. They have now begun to form a council for the purpose of implementing this on a wider scale.

It was felt by 10 meter interests in this area that with all the band plans that have been proposed, and with everyone taking off in different directions as was the case before the days of repeater councils for relay communications, some organization has to be formed for voluntary coordination of 10 meter non-relay channelized operation. I spoke with Norm the other morning via WR6ABN and on .52 simplex, and he told me that a pilot organization has been formed and that they would soon be holding an open meeting to adopt a title, construct a constitution and bylaws, and formalize the organization.

As I have been led to understand, this organization intends to adopt the southern California 10 meter band plan which was presented earlier in this magazine, and possibly coordinate specific forms of activity or utility to each channel. It's too early to even surmise the kind of impact that this will have on the future of non-relay operation on 10 meters — and on non-FM operation as well. One thing is sure, though: 10 meters AM is possibly the biggest thing to hit the southland since the two meter repeater. It was only a matter of time until some form of organization to direct its growth took root out here.

WHEN ALL ELSE FAILS, TRY MY ANSWERING MACHINE

Take this number down. If you have something that you feel the rest of your peers may be interested in but don't have the time to write a letter, you can place a call anytime, 24 hours a day, to my unofficial "LW" hotline at (805) 259-8243. One catch, though: My machine will only take a fifteen second message. If you plan to call in, I suggest that you write down what you intend to say and then edit it to the most necessary information. Start with your name and callsign when you hear the first "beep," and stop when you hear the second "beep." I will try to send you a postcard within a few days to confirm the receipt of the information.

One such piece of information that came to me via "Elmo" (the pet name for our answering machine) is this, passed on from Oliver W7WEW to K6UQJ via Westcars and then via phone to me. It concerns a brand new repeater system serving the area around Prescott, Arizona, from a point 7800 feet up atop Mingus Mountain. Its callsign is WR7AFC, its channel pair is 147.60 in/147.00 out, and it's open for all to use.

AMSAT

AMSAT has received Circular No. 1273 dated July 12, 1977, of the International Telecommunication Union's International Frequency Registration Board giving advance publication information on a planned amateur satellite network of the USSR. The published information is summarized below.

General Information: "The USSR Administration wishes to inform countries, members of the ITU, that the USSR is working on the establishment of an amateur-satellite service system. This system 'RS' will be based on 3-4 satellites on a circular near-polar orbit. The amateur satellite stations are designed for multiple access with re-transmission and frequency translation without demodulation on a real time scale."

Date of bringing into use: 1977-1978.

Number of satellites: 3-4.

Orbital information: Inclination, 82°; Altitude of apogee & perigee, 950 km (circular orbit); period, 102 minutes.

Uplink characteristics: 145.8-145.9 MHz (100 kHz bandwidth); quarter-wave receiving antenna, circularly polarized; user uplink power, 10-15 Watts to 10-12 dB antenna; transponder receiver noise temperature, 3000° K.

Downlink characteristics: 29.3-29.4 MHz (100 kHz bandwidth); half wave transmitting antenna, circularly polarized; transponder power, 1.5 Watts peak to 0 dB gain antenna.

Maximum communications distance: 6,000 km (3,700 st. mi.).

From the advance publication orbital information, it seems likely that the "RS-OSCARs" will be launched piggyback with the Meteor meteorological satellites from the Plesetsk launch site.

VK/ZL/OCEANIA CONTEST

Phone
Starts: 1000 GMT
Saturday, October 1
Ends: 1000 GMT
Sunday, October 2
CW
Starts: 1000 GMT
Saturday, October 8
Ends: 1000 GMT
Sunday, October 9

Sponsored by the Wireless Institute of Australia. Entry classifications: single transmitter-single op, multi-op (outside VK/ZL only).

EXCHANGE:

RS(T) plus serial number starting at 001.

SCORING:

Oceania stations score 2 points per QSO with VK/ZL, 1 point for QSO with Oceania other than VK/ZL. All other stations score 2 points per VK/ZL QSO, 1 point per Oceania (other than VK/ZL) QSO. Final score is derived by multiplying total QSO points by the sum of VK/ZL call areas worked on all bands. The same VK/ZL call area worked on different bands counts as a separate multiplier.

ENTRIES AND AWARDS:

Logs must show, in this order: date/time in GMT, callsign of station contacted, band, serial number sent/received. Underline each new VK/ZL call area contacted and make separate logs for each band. Summary sheet must show callsign, name, address (please use block letters), details of equipment used, and for each band — QSO points for that band and total of VK/ZL call areas worked on that band. All band score will be total QSO points multiplied by sum of VK/ZL call areas on all bands while single band scores will be that band's QSO points multiplied by VK/ZL call areas worked on that band only. Attractive colored certificates will be awarded top scorers. You may obtain contest results and next year's rules by enclosing one IRC or mint stamps of your country to value of one IRC. Certificate winners will receive results and next year's rules regardless. Send entries to: WIA-VK/ZL Contest Manager, GPO Box 1002, Perth, 6001, Western Australia, or WIA-VK/ZL Contest Manager, N. Penfold VK6NE, 388 Huntriss Road, Woodlands, 6018, Western Australia — posted to reach Australia before Jan. 31.

OCTOBER QRP QSO PARTY

Starts: 2000 GMT
Saturday, October 8
Ends: 0200 GMT
Monday, October 10

Sponsored by the QRP Amateur Radio Club International Inc., this contest is open to all amateurs and all are eligible for awards. Stations can be worked once per band; general call is CQ QRP DE . . .

FREQUENCIES:

CW — 3540, 7040, 14065, 21040, 28040. SSB — 3855, 7260, 14260, 21300, 28600. Novice — 3720, 7120, 21120, 28040. All frequencies ± 5 kHz to avoid QRM, as license permits.

EXCHANGE:

Members send RS(T), state, province, or country, and QRP number. All others send RS(T), state, province, or country, and power input.

SCORING:

Each member QSO counts 3 points, non-members count 2 points per QSO, stations other than W/VE count as 4 points. Multipliers based on input power of transmitter: greater than 100 Watts — x1; 25 to 100 Watts — x1.5; 5 to 25 Watts — x2; 1 to 5 Watts — x3; less than 1 Watt — x5. Total score is QSO points times total number of states or provinces or countries per band times power multiplier.

ENTRIES AND AWARDS:

Certificates to highest scoring station in each state, province, or country, other places depending on activity. One certificate for the station showing three "skip" contacts using the lowest power. Send full log data, including full name, address, and bands used, plus equipment, antennas, and power used. Entrants desiring results please enclose a #10 SASE. Logs must be received by Nov. 30 to qualify. Send all entries to: QRP ARC Contest Chairman, E. V. Sandy Blaize W5TVW, 417 Ridgewood Drive, Metairie LA 70001.

MANITOBA QSO PARTY

Starts: 2200 GMT
Saturday, October 15
Ends: 0200 GMT
Monday, October 17

Sponsored by the Amateur Radio Clubs of Manitoba and dedicated to ARLM (Amateur Radio League of Manitoba) to commemorate their 25th anniversary in 1977. Stations may be worked once per band and mode. VE4 mobiles can be worked each time they change municipalities. ARLM members will be bonus stations for out of province contacts. VE4 to VE4 and 2 meter simplex QSOs will be permitted.

EXCHANGE:

RS(T), name, QTH (municipality for VE4).

SCORING:

VE4s multiply number of QSOs times number of US states, VE provinces, and DX countries. All others multiply number of QSOs times number of Manitoba municipalities, local government districts, provincial parks, and forest reserves (134 max.) times the number of ARLM members worked.

FREQUENCIES:

SSB — 3770, 3905, 7195, 7230, 14190, 14285, 21245, 21355, 28600. CW — 3705, 7105, 14065, 21205, 28205.

ENTRIES AND AWARDS:

Certificates to high score in each province, state, and country. Plaques for high VE4 and high out of province station. Additional plaques if warranted. Send log data and signed declaration no later than Nov. 14 to: Doug Bowles VE4QZ, 1104 First Street, Brandon, Manitoba, Canada R7A 2Y4.

CQ WE CONTEST

October 22 and 23

See schedule for times and frequencies!

Sponsored by the Murray Hill ARC, the contest is open to all licensed amateurs employed by or retired from Western Electric, Bell Labs, and Teletype Corp. Also, participation of employees and retirees of AT&T and AT&T Long Lines is permitted. The contest is divided into four sessions with a total allowed operating time of 20 hours. A separate QSO may be made with a station on each of three modes — phone, CW, and RTTY. No form of cross mode, cross band, or repeater operation will be permitted. There is nothing in the rules to prohibit operation outside of the suggested schedule, but it is hoped that by using the schedule as a guide, many more QSOs will be made by knowing when and where to listen. If conditions do not favor a particular band called for in the schedule, participants are free to move elsewhere, preferably to the next band scheduled. However, please observe the contest time periods. Each station must be operated by a single operator with a single transmitter. Club stations operated under the club station callsign may compete to submit a score for that location's total. These contacts may not, however, be counted toward an individual's personal score. Successive contacts with the same station may not be made by changing mode! Violation of any rules of this contest, or any of the current FCC rules and regulations governing amateur radio service, can result in disqualification of the station involved.

EXCHANGE:

RS(T), name, location code. A location shall be counted once for each band for which that location is worked in each of the three contest sections.

SCORING:

Contacts with a Novice or Technician on an HF or CW Novice band will count 10 points; contacts with a retiree will count 5 points; all other contacts count 1 point.

ENTRIES:

All logs must be in GMT and should be forwarded to your local "Works Coordinator" as soon as possible after the contest. They should be to your coordinator no later than Nov. 15. All local coordinators should forward their location summary and log sheets to reach Murray Hill by Dec. 15. In order to create an incentive to get your logs in, you may add 10 points to your score if you sign a statement that your entry was forwarded to

CALENDAR

Oct 1	Open CD Party — CW
Oct 1-2*	California QSO Party
Oct 1-2	VK/ZL/Oceania — Phone
Oct 8-9	VK/ZL/Oceania — CW
Oct 8-9	RSGB 21/28 MHz Phone Contest
Oct 8-10	October QRP QSO Party
Oct 12-13	YLRL Anniversary CW Party
Oct 15-16	Open CD Party — Phone
Oct 15-16	RSGB 7 MHz Phone Contest
Oct 15-17	Manitoba QSO Party
Oct 22-23	CQ WE Contest
Oct 22-23	CARTG RTTY Sweepstakes
Oct 29-30	CQ WW DX Phone Contest
Nov 3-4	YLRL Anniversary Phone Party
Nov 5-6	ARRL Sweepstakes — CW
Nov 5-6	RSGB 7 MHz CW Contest
Nov 12-13	IPA Contest
Nov 12-13	European DX Contest — RTTY
Nov 12-13	Missouri QSO Party
Nov 13	OK DX Contest
Nov 19-20	ARRL Sweepstakes — Phone
Nov 19-20	WWDXA International CW Contest
Nov 19-20	All Austria Contest
Nov 26-27	CQ WW DX CW Contest
Dec 3-4	ARRL 160 Meter Contest
Dec 10-11	ARRL 10 Meter Contest

*Described in last issue.

TIME AND FREQUENCY SCHEDULE FOR CQ WE CONTEST

Session One: HF/VHF Phone — 1700 to 2200 UTC Oct. 22, 1977
Suggested operation:

1700-1800	VHF/160 meters
1800-1900	10 meters
1900-2000	15 meters
2000-2100	20 meters
2100-2200	40 meters

Session Two: HF/VHF CW and RTTY — 2300 UTC Oct. 22 to 0400 UTC Oct. 23, 1977
Suggested operation: CW on the hour, RTTY on the half hour.

2300-0000	20 meters
0000-0100	40 meters
0100-0200	VHF/160 meters
0200-0300	80 meters
0300-0400	80 meters

Session Three: HF/UHF CW and RTTY — 1700 to 2200 UTC Oct. 23, 1977
Suggested operation: CW on the hour, RTTY on the half hour.

1700-1800	VHF/160 meters
1800-1900	10 meters
1900-2000	15 meters
2000-2100	20 meters
2100-2200	40 meters

Session Four: HF/VHF Phone — 2300 UTC Oct. 23 to 0400 UTC Oct. 24, 1977
Suggested operation:

2300-0000	20 meters
0000-0100	40 meters
0100-0200	VHF/160 meters
0200-0300	80 meters
0300-0400	80 meters

Suggested Frequencies:

Band	CW	RTTY	Phone
160	Use segment permitted locally		
80	3540-3570, 3730	3605	3900-3960
40	7040-7080, 7130	7055	7260-7300
20	14040-14050	14080	14280-14330
15	21040-21080, 21140	21095	21380-21420
10	28150	28150	28675
6	50.1-50.13	50.1-50.13	50.1-50.13
2	145.05-145.1	145.05-145.1	145.05-145.11, 146.52

your local works coordinator before Tuesday, Nov. 1.

CARTG RTTY SWEEPSTAKES

Starts: 0200 GMT
Saturday, October 22
Ends: 0200 GMT
Monday, October 24

Sponsored by the Canadian Amateur Radio Teletype Group, VE3RTT. Not more than 30 hours of operation is permitted, with non-operating periods taken at any time during the contest. Summary of times on and off must be submitted with score. Use all amateur bands authorized for F1 emission (RTTY). Country status as per ARRL country list; KL7, KH6, and VO to be considered as separate countries. Classes of entry include: single op, single transmitter; multi-op, single transmitter; and SWL printer. Individual operators of multi-operated stations may submit their logs singly instead of a group log.

EXCHANGE:

Messages will consist of message number, time in GMT, and zone.

SCORING:

All 2-way RTTY QSOs with own zone will earn 2 points; all others as per CARTG zone chart (send SASE if needed). Stations may not be contacted more than once on any one band. Multiplier is number of different countries contacted including one's own on each band. Each US and VE district also counts as a separate country. Total score is total number of exchange points times number of countries worked times number of continents (6 max.). Canadian bonus points to be added last — 100 bonus points for each VE/VO contact on all bands.

ENTRIES AND AWARDS:

Use separate log sheet for each band. Log sheets and zone charts available from CARTG for SASE or IRCs. Logs must be received before December 31 to qualify. Engraved plaques to top 10 scorers plus 6 special categories. Certificates to top scorers in each US and VE/VO district and each country. Send logs, summary, and scores to: CARTG — VE3RTT, 85 Fifeshire Rd., Willowdale, Ontario, Canada M2L 2G9.

CQ WORLDWIDE DX CONTEST

Starts: 0000 GMT
Saturday, October 29
Ends: 2400 GMT
Sunday, October 30

Sponsored by *CQ Magazine*, the contest is open to all amateurs worldwide. Use all amateur bands, 160 through 10 meters. Entry classifications include: single op, single and all band; multi-op (all band), single or multi-transmitter.

EXCHANGE:

RS(T) and zone.

SCORING:

Contacts between stations on different continents count 3 points; stations on same continent but different countries 1 point, except for North American stations only! — contacts between stations within North American boundaries count 2 points. Contacts between stations in the same country are permitted for zone or country multiplier credit, but have zero point value. Multipliers are number of different zones on each band and different countries on each band. Final score is result of total QSO points multiplied by sum of zone and country multiplier.

ENTRIES AND AWARDS:

Many various awards in different classes and categories. Plaque to highest club score. Logs should include all times in GMT; indicate zone and country multipliers only first time worked on each band. Logs must be checked for duplicate contacts; use separate sheets for each band. Each entry must be accompanied by a summary sheet showing all scoring information, category of competition, name and address in block letters, and a signed declaration that all contest rules and regulations have been observed. Official logs and summary sheets and zone maps are available from *CQ*; include a large SASE. All entries must be postmarked no later than Dec. 1 for phone and Jan. 15 for CW. Send logs to: CQ WW Contest Committee, 14 Vanderventer Avenue, Port Washington, LI, NY USA 11050.

Check *CQ Magazine* for any last minute rule changes!

ISLANDS OF THE WORLD AMATEUR RADIO ACHIEVEMENT AWARD

Sponsored by amateurs residing on Whidbey Island, the award is available to all licensed amateurs in the world. All contacts must be made after October 1, 1977! The award will be issued for: 50 islands, including contact with Whidbey Island; 100 islands, including contact with Whidbey Island; 150 islands, including contact with Whidbey Island; maximum possible, including contact with Whidbey Island.

Islands are taken from the "prefix by countries list" as they appear in the *Radio Amateur Callbook*, with the exception of Whidbey Island. Each island must also be recognized as such by the National Geographic Society. To obtain the award, proof of contact must be submitted on a self-prepared list showing the island's name, callsign of amateur contacted, date of contest. This list should be arranged in alphabetical order by island. *Do not send QSL cards!* This list must be verified by at least two amateurs, General class or above, or by a local radio club secretary. Send your verified list of contacts, which must include Whidbey Island, $1.00, and a self-addressed stamped envelope, to: Bill Gosney WB7BFK, 4471 40th N.E., Whidbey Island, Oak Harbor WA 98277 USA. Foreign amateurs may exclude the fee and stamps on their return envelopes.

The rules that govern this award will be reviewed annually on October 1!

CARTG MERIT AWARD

A plaque has been offered for this award complete with engraving, and the CARTG is requesting names of suggested qualifiers. The award was created in 1967 to be presented annually to the radio amateur chosen for his outstanding contribution to the art of amateur radio teletype communications. It need not necessarily be confined to technical contributions but recognition of any outstanding achievement worldwide: experimental work, articles, traffic handling, net operation, DX, or any other outstanding RTTY achievement. Send complete information to: CARTG — VE3RTT, 85 Fifeshire Rd., Willowdale, Ontario, Canada M2L 2G9.

ALL VE/VO ON RTTY

The CARTG is also offering a certificate to anyone working all VE/VO on RTTY. There is no charge for the award, but QSLs must be included with the request and will be returned. An official of a RTTY group or society may inspect and send a *signed* list of such QSLs in place of sending the actual cards. Send all requests to CARTG — VE3RTT, 85 Fifeshire Rd., Willowdale, Ontario, Canada M2L 2G9.

New Products

JMR MOBILE-EAR CLEAR-1 MICROPHONE

A common problem faced by FM and SSB operators is inadequate microphone gain and directivity. A poor mic can make a TS-820 or Hy-Gain 3750 sound like an early phasing rig. Most modern FM transceivers employ audio limiting circuits which are designed to provide consistent modulation under differing audio conditions. Unfortunately, most "stock" microphones do not have sufficient output and the directional capability required to enhance the transceiver with which they are used.

This month I reviewed the Clear-1 microphone by JMR Systems Corp. The Model 40 mic is advertised as a high output device, capable of driving any audio circuit to its fullest extent. The mic is also highly directional, allowing it to be used in noisy mobile environments.

All it takes is one look at the Model 40 Clear-1 to realize that something is different. The microphone is shaped like a small Derringer pistol, with a push-to-talk button on one end. The microphone element is a capacitor device, mounted behind a tiny brass screen on the top of the transducer. The Model 40 contains a built-in FET preamp requiring an internal battery, and a variable gain control is provided. A five conductor cable is used to interface the user-supplied mic connector. Normally open and normally closed PTT contacts are available, allowing the Clear-1 to be used with any transceiver. Mic output is a high -42 dB, and audio response is 200-600 Hz . . . most definitely communications quality! The high upper-end frequency response is responsible for the quality "sound" of the Model 40.

I tested the JMR mic with the Hy-Gain 3750 transceiver on 20 and 75. Good reports were received – with the compressor in the 3750 disabled. The output control on the mic can be left about one-eighth open under normal "close-talk" conditions. I found that it was possible to clip the Hy-Gain by using excessive mic output – a good audio reserve is present! By carefully adjusting the JMR's level control, I was able to hold the mic at arm's length and talk in a normal tone . . . undetected by the listening station.

I have a popular 2m SSB transceiver in my shack – when I use it with those who know me, I am accused of having a cold or some other disgusting nasal malady. The standard mic supplied with this rig does not cut it, a classic case of anemic audio. This rig was the perfect test situation for the Model 40 on VHF. I changed microphone connectors and fired up. Amazing – no more Donald Duck with the flu! The transceiver sounded like its designers had intended. It was not possible to overdrive the 2m rig, probably because the audio limiter has good range.

The only shortcoming I noted is the lack of VOX capability with the Model 40. Since the internal preamp is battery powered, it would have to be continuously activated for VOX operation. This limitation is understandable when it is considered that the Clear-1 was indeed designed for mobile operation. I normally use PTT on HF, so it didn't make any difference.

In my opinion, the Mobile-Ear mic performed exactly as specified. Its performance on VHF was most impressive. The mic is light enough to survive even the longest "white-knuckle" sessions. It should also be indicated that the JMR Clear-1 microphone is compatible with most CB transceivers! The microphone is priced at $44.95. *JMR Systems Corp., 168 Lawrence Rd., Salem NH 03079.*

RADIO SHACK TRS-80 MICROCOMPUTER SYSTEM

Computers are about to become a part of everyday life in American businesses, schools, and homes, according to Radio Shack, the nationwide electronics store chain.

The company has just introduced their new Radio Shack TRS-80 Microcomputer System. Not a kit, the TRS-80 comes completely wired and tested, ready to plug in and use.

The TRS-80 system consists of a 53-key professional-type keyboard and microcomputer plus regulated power supply, a data cassette recorder which is computer-controlled through an interface, and a 12" video display monitor.

A comprehensive owner's manual will be supplied with the TRS-80 that will explain everything necessary for its operation, from plugging it in through programming.

Radio Shack will also supply prerecorded cassette programs for such applications as a small business payroll, general ledger accounting, accounts receivable, and inventory control.

For educational purposes, the microcomputer can be used to teach mathematics, music theory, and virtually any subject through programmed teaching methods.

Just for fun, a variety of game programs will be available, including blackjack and backgammon. Other uses around the home would be personal finance management, storage of recipes, menu planning, and use as a message center.

Provisions have been made in the TRS-80 for later addition of accessory, or "peripheral," items such as an additional tape recorder, "disk" programming, and a printer which would create a permanent, typed record of the computer output.

At the heart of the Radio Shack TRS-80 Microcomputer System is a Z-80 microprocessor chip that serves as the central processing unit, or "brain," of the microcomputer. This remarkable device, about the size of a watermelon seed, is one of the most advanced microprocessor chips available today.

The Radio Shack TRS-80 Microcomputer System is priced at $599.95, complete with video display monitor and data cassette recorder. The microcomputer alone will sell for $399.95.

Leading the way in electronics since 1921, Radio Shack is a division of Tandy Corporation (NYSE), headquartered in Fort Worth, Texas, which is also where the TRS-80 is manufactured. Radio Shack presently has more than 6,000 stores and dealers in all 50 states and Canada, as well as nearly 500 stores overseas operating under the name Tandy International Electronics. *Radio Shack, 2617 West Seventh Street, Fort Worth TX 76107.*

FLESHER PS-170 RTTY PRESELECTOR

Last month I described the new RTTY terminal unit from Flesher Corp., the DM-170. This device has considerable built-in filtering which allows good isolation of the mark and space tones. However, in conditions of extreme QRM and noise, additional selectivity is required to reliably copy RTTY signals. Flesher has responded to this need by providing an active filter preselector that can be used with the DM-170 TU, or any other demodulator.

The PS-170 filter is connected between the receiver's audio output and the input of a terminal unit. This allows narrow shift (170 Hz) tones to pass, and not much else. The PS-170 has two outputs. The normal output couples the filter directly to the TU, while the limiter output provides an additional stage of hard limiting, which removes amplitude variations from the received signal.

The PS-170 is tiny. It consists of a 2" x 2" PC board, which can be mounted in any existing enclosure. Requiring ±15 V dc at 12 mA, the PS-170 can steal power from the terminal unit, or may be powered from a simple, zener regulated supply. I found that the preselector operated fine on voltages between 12 and 15. The 3 dB bandwidth of my PS-170 is 400 Hz, between the frequency range of 2000-2400 Hz. This differed

JMR Clear-1 microphone.

The new Radio Shack TRS-80 Microcomputer System features a built-in 53-key professional-type keyboard and one of the most advanced microprocessor chips available today, the Z-80.

slightly from the published frequency range of 2025-2400 Hz. I measured frequency response with an audio oscillator and VTVM, using the non-limited output.

Careful tuning is required when using the PS-170. The bandpass is such that even slight mistuning causes the tones to be excessively attenuated. However, the reception quality under heavy QRM and noise is fantastic! I used the DM-170 and ST-5 for comparison tests. The PS-170 was switched between the two terminal units, and under conditions of extreme interference was the difference between copying and missing weak RTTY signals. The DM-170 already has bandpass filters incorporated; the ST-5 does not. Thus, the ST-5 benefitted most when the PS-170 was used. I have since incorporated the PS-170 into the same cabinet with the Flesher TU. An SPDT switch selects either the normal or limiting output.

The PS-170 is available in kit or factory-built form. The kit takes about one half hour to build and align. The components are all resistors, capacitors, and ICs. Tune-up is accomplished in the same manner as was used in aligning the DM-170. Resistors are substituted into the circuit until the proper response is obtained – the op amps require only resistance changes to modify the response curve – no 88 mH toroids to prune! The Flesher PS-170 is priced at $11.95 in kit form and $18.95 factory assembled and aligned. *Flesher Corporation, Box 902, Topeka KS 66601.*

NEW PERSONAL COMPUTER FROM OHIO SCIENTIFIC

Challenger IIP from Ohio Scientific is an exciting new personal computer complete with BASIC in ROM and RAM (4K) for programs in BASIC. All you have to do is turn it on and go!

Challenger IIP is a fully self-contained personal computer with a full size keyboard and a 32 x 64 character video display interface.

Complete with an audio cassette interface, the Challenger IIP simply connects to a video monitor or home TV set via an rf converter (not supplied). A cassette recorder can be used for program storage.

Challenger IIP comes complete with a 4 slot backplane and case for $598.00 fully assembled, and is expandable via compatibility with all Ohio Scientific computer accessories. *Ohio Scientific, Hiram OH 44234.*

GARY MODEL 101 DIGITAL VOLTMETER KIT

A complete DVM kit for $29.95? You've got to be kidding! That's what I thought when I received the Gary McClellan Model 101 Digital Voltmeter kit to review. Why not? The end result of the kit is a four digit DVM, complete with sign, auto zero, and overvoltage blanking!

The DVM market is similar to the calculator industry. Several years ago, the DVM was an exotic test instrument found only in electronic labs. Capable of extreme accuracy, the DVM is based on an LSI A/D (analog to digital) converter. The output of the converter is multiplexed and displayed on seven-segment displays, exactly as in some digital clocks. The price of DVM chips has plunged, aided by the mass production of calculator and microprocessor chips. The Gary DVM is based upon the Motorola MC14433 A/D converter, and has a basic range of 0-±1.999 volts.

The Gary DVM took exactly two hours to build and calibrate. The display mounts on a small PC board, which is fastened to the larger DVM board. All components appear to be quality devices, and the CMOS chips are first run units! Molex pins are used to mount the DVM chip and two other CMOS packages. The four digit display is multiplexed to reduce power consumption. The associated transistors and resistors for the display require a bit of close wiring, but Gary's eleven page manual contains detailed instructions and several photos of the completed unit. No special problems were encountered while wiring the kit.

The most enjoyable part of kit building (for me) is applying the juice for the first time. It sure is nice when things perk right from the opening gun, but I was doomed to disappointment this time. The Model 101 requires a single five volt supply, which should be regulated. I happened to have a little supply based on an LM-309K which was used in microprocessor experiments. I connected the supply, turned it on, and nothing! Then I thought I had better read Gary's instructions. There is a single screwdriver resistor that is used to calibrate the DVM. My control was all the way to one end; that's why the display was dark. Shorting the probe leads, I adjusted the control, and sure enough, the display illuminated. I adjusted for a reading of -000 volts, which is the normal condition with no signal input. The minus sign blinks to indicate that the DVM is functioning.

I should have read further, because the next thing I did was connect a handy 9 V transistor to the DVM. The display blanked out! Again consulting the manual, it turns out that the 101 DVM has a basic range of 0-1.999 volts. Any overvoltage blanks the display – a nice touch! Calibration is accomplished by adjusting the control until the reading corresponds to a known source. I used the Gary Model 120 DVM calibrator, which I will review next month. A good reference source is a single mercury cell, which has a no load voltage of 1.35 volts, or very nearly that. After calibrating the 101, I checked my year-old standard mercury cell. Not bad, 1.352 volts. Amazing!

The 101 DVM has a sign function, which means the probes do not have to be reversed when measuring minus voltages. It looks like I will have to retire my old trusty Knight VTVM – boy, I sure hate the constant reversing of the polarity switch!

The only problem, if you can call it a problem, is the low range of the 101 basic DVM. An attenuator is required to measure voltages of greater magnitude than 1.999 volts. Gary provides an attenuator for his DVM, the Model 101-1 four range kit. It includes a .05% resistor network and switch. The accuracy of the basic kit is .05%, so make sure to use quality resistors if you build your own attenuator.

All in all, I am very impressed with the 101 DVM. Its features are found on much more expensive devices, and the quality, accuracy, and flexibility are hard to beat in a $29.95 kit! It is small enough to custom mount, and can be used as the basis for a complete multimeter or digital tuning display. The input impedance is 1000 megs, and it only draws 80 mA maximum at 5 volts. Gary also provides a full line of of accessories for the 101 DVM. *Gary McClellan Company, 1001 W. Imperial Hwy., La Habra CA 90631.*

NEW SERIES OF FREQUENCY SYNTHESIZED TWO METER AMATEUR TRANSCEIVERS, AMPLIFIERS, AND ANTENNAS FROM HALLICRAFTERS

Darrell Fletcher, Chairman of the Board of the Hallicrafters Company, and Cliff Mathews, Vice President of this leading manufacturer of para-military and government FM and SSB portable and manpack communications systems for the international market, have announced the introduction of a new series of two meter transceivers, amplifiers, and antennas for the domestic USA amateur market and international markets.

The new series of amateur transceivers features a military-type frequency synthesizer for up to 800 channel operation in 5 kHz steps in the FM mode and digital frequency readout for operating on both simplex and repeater modes. The all solid state rf power amplifiers provide up to 1/4 kilowatt power output on FM and up to 300 Watts peak envelope power on SSB for either base or mobile operation. Completing the new equipment series is Hallicrafters' new line of two meter base and mobile antennas having high rf power handling qualities and featuring a magnetic mount mobile antenna for easy installation and removal.

"Hallicrafters' new line of two meter amateur equipment is a natural expansion of Hallicrafters' traditional line of VHF and UHF-FM and HF-SSB communications products sold in international markets," says Darrell Fletcher. "The frequency coverage plan features and 5 kHz channel spacing enables the equipment to be used in any market in the world," claims Mathews, who says the equipment will be marketed directly in the USA and Canada by selected amateur equipment dealers and internationally by Hallicrafters International, Inc.

Communicate On 10.25 GHz

-- with a simple transceiver

Many hams feel that the world of amateur radio ends at two meters, or even twenty in some cases! As the frequency increases, the amount of commercially available gear diminishes. Above 450 MHz, the operator must build his equipment – little prebuilt equipment is around. Thus, the bands above 450 are underpopulated, and misunderstood by the majority of hams. Possibly you have eyed those "microwave" frequencies starting at 1220 MHz . . . and wondered how to operate or experiment there. Well, let's see . . . 1296 might not be too bad – you can triple an old Motorola transmitter strip, and come up with a converter for your 2m rig. Definitely a project for two hams, as it is nice to have someone to talk with after the construction is done! However, if you desire to experiment with waveguide, horns, and point-to-point communications, the 10.5 GHz band is the place to go.

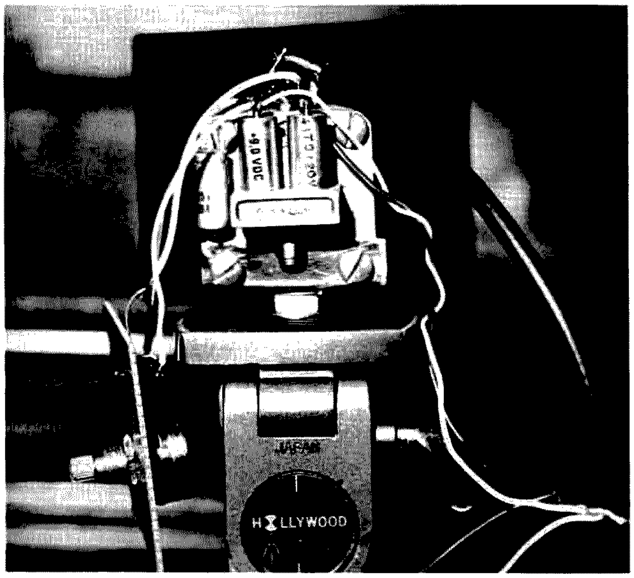

Fig. 1. A rear view of the Microwave Associates MA-87108 Gunnplexer. The Gunn diode is in the cavity under the left barrel. The tuning varactor diode is under the right barrel. Electrical tuning control is mounted on the perfboard, and the i-f connection is visible at the top of the rf head. The homemade bracket for tripod mounting is attached to the lower two bolts. A ¼ inch nut is sweat soldered to the bottom of the copper flashing. Refer to the text for details.

Why 10.5 GHz? The possibilities for experimentation are endless. If you need a true point-to-point link for your repeater, microwaves are the answer. A low power link can provide reliable control for remote bases, with a lower long-term cost than phone lines! Everyone is familiar with police radar, which is, incidentally, located just above the ham band. Experiments with Doppler radar are possible on 10 GHz.

The road to 10 GHz has not been easy. Little military gear is available, and a machine shop is often required to build microwave gear. The problem of equipment has stifled most amateur ventures into the world of microwaves. However, this problem no longer exists!

Enter the Gunnplexer

A progressive company in Massachusetts has introduced a line of microwave gear specifically designed for amateurs operating on 10.5 GHz. Microwave Associates, Inc., provides a microwave transmitter and receiver front end in a single package. Dubbed the Gunnplexer, this device produces 20 mW of microwave energy. A portion of that energy is coupled to a receiving diode, which, in the presence of another microwave signal, produces a low frequency i-f signal. The Gunnplexer is easily incorporated into a complete communications system. All that is needed is a Gunnplexer, i-f receiver, and power supply. This article describes just such a system. This transceiver can be used for two-way communications on 10.5 GHz, as a control link, or for Doppler effect radar. Before starting, let's look at the Gunnplexer and discuss its operation.

A Gunn Diode Is the Key

The Gunnplexer consists of five main parts. The heart of the rf head is a Gunn diode. This diode produces a microwave energy directly from dc when it is properly mounted in a resonant cavity. Similar to the familiar tunnel diode, the Gunn diode exhibits a negative resistance region under certain bias conditions. Microwave oscillations occur in this region. The diode employed in the Gunnplexer produces about 20 mW at 10 volts. Current drain is about 225 mA. Referring to Fig. 1, the Gunn diode is contained in the left barrel on the rear of the rf head.

The second component of the device is a varactor diode, housed in the right barrel, next to the Gunn diode. The varactor is used to control the frequency of the microwave radiation. If af modulation is applied to the varactor, FM will occur. The varactor can shift the frequency of the Gunnplexer 60 MHz. A crystal or other high output microphone may be coupled directly to the diode – no preamp is required on a simple system.

The receive components

comprise the third and fourth areas of the Gunnplexer. A tiny portion (about .5 mW) of the transmitted energy from the Gunn diode is coupled to a microwave mixer diode. An i-f signal is produced when a received signal is heterodyned in the mixer. Mixer injection is accomplished by a ferrite "circulator," located next to the mixer diode (Fig. 3). Injection is also controlled by a screw protruding into the body of the Gunnplexer. The standard i-f frequency used by amateurs is 30 MHz. However, different i-fs can be produced by mechanical and electrical tuning of the Gunnplexer. Remember, the transmitted signal also provides mixer injection! A standard FM broadcast receiver can be used as the i-f receiver in a simple transceiver. More on this later!

The normal Gunnplexer frequencies are 10.250 and 10.280 GHz. Thus, it can be seen that the difference frequency is 30 MHz, even though the local oscillator injection is different at each end of the communications link.

The last major part of the Gunnplexer is, as expected, an antenna. The body of the Gunnplexer is actually a section of UG-39/U waveguide. This guide can be bolted to transmission waveguide, or a gain horn antenna may be attached. Microwave Associates provides a 17 dB gain horn for the Gunnplexer (Fig. 4).

Using the Gunnplexer as a Transceiver

A microphone, i-f receiver, and power supply is required to turn a Gunnplexer into a complete transceiver for 10.25 GHz. A well-regulated 10 volt supply is required for the Gunn diode. About 4.5 volts of bias is needed for the varactor to maintain frequency. The Gunn diode output drifts as temperature changes, at a rate of -350 kHz per degree Centigrade. Quite a drift factor!

Thus, a change in temperature of only a degree will move the Gunnplexer frequency 350 kHz – right out of your i-f passband! In some cases, afc is required to maintain communications, especially when a narrow i-f passband is employed. A simple transceiver can use a voltage divider with the varactor supply to "tune" the Gunn transceiver. This scheme is adequate, especially in a system with wideband i-f capability. Refer to Fig. 2 for details of the bias voltage divider.

The most important element (next to the Gunnplexer) in the transceiver is the i-f receiver. A low noise figure is required. The i-f channel must also match the 200 Ohm impedance of the mixer diode for optimum results. Of course, the receiver must have an FM detector! An additional consideration is the i-f bandpass characteristic. If a narrow (10 kHz) i-f is used, Gunnplexer range increases – up to 100 miles under good conditions!

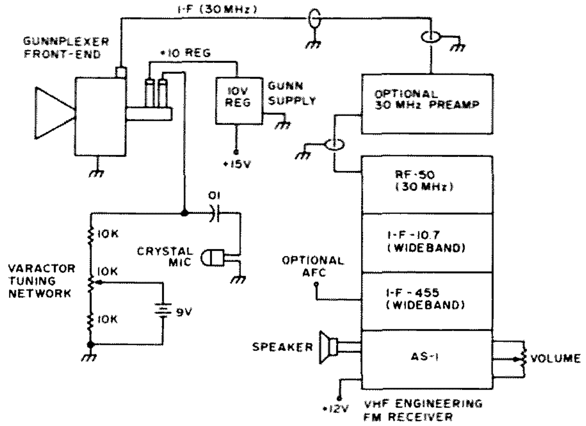

Fig. 2. Block diagram of the simple Gunnplexer transceiver. Details of the bias supply are shown, as well as all interconnections. This circuit uses VHF Engineering receiver strips for the receiver i-f and FM detector. A National Semiconductor LM-317 regulator chip is employed to provide the 10 volts required by the Gunn oscillator.

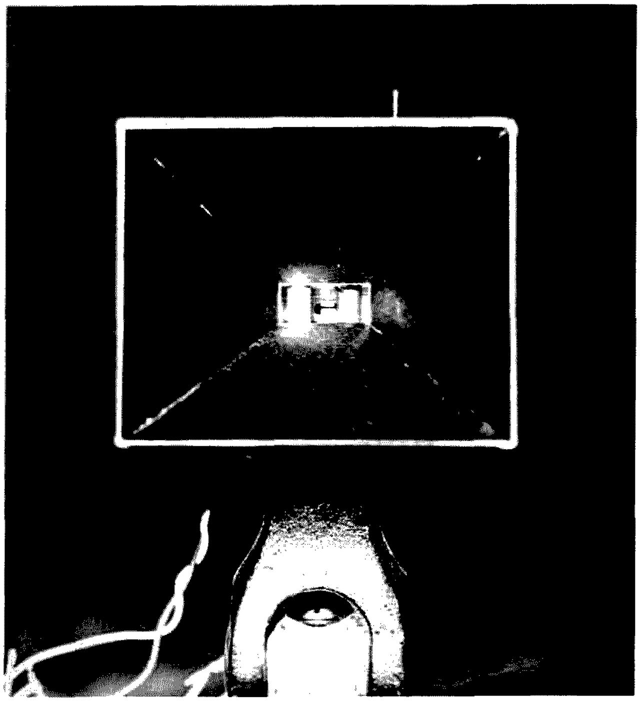

Fig. 3. Big Brother is watching you! This shot shows the mixer diode (left) and the ferrite mixer circulator in the waveguide. The tuning screw can be seen between the diode and circulator. Microwave energy is generated in the cavity behind the oval "iris," which is visible directly behind the tuning screw. The wire extending from the top of the horn is not a scratch in the photo, but rather a ground bus mounted on the rf head.

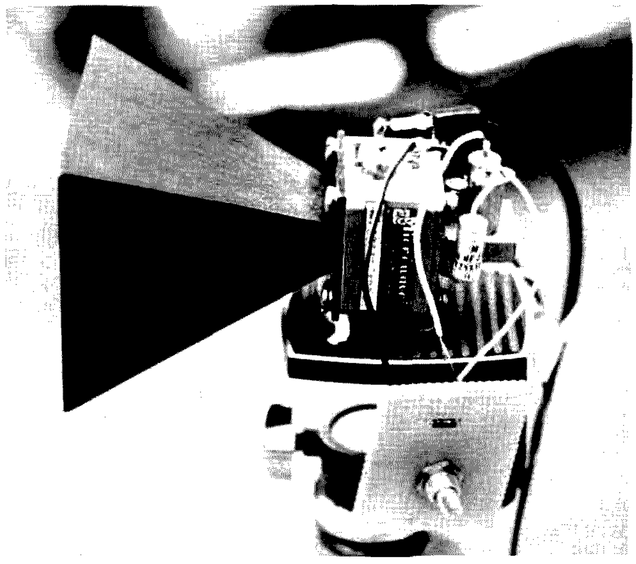

Fig. 4. Side view of the Gunnplexer. The 17 dB horn is clearly visible, as well as the tuning control, cavity, and mounting bracket.

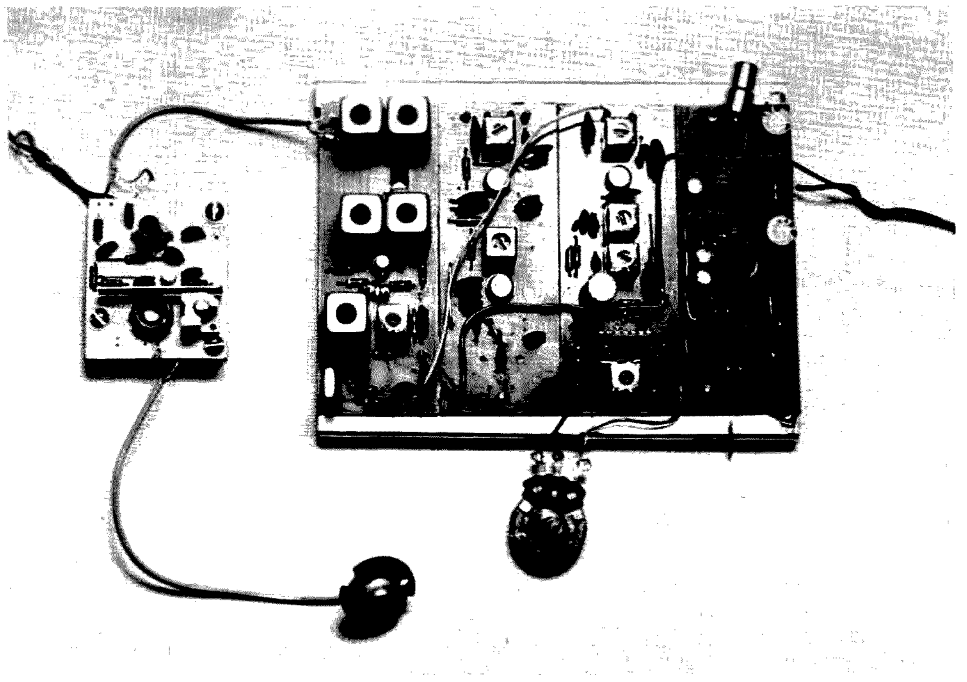

Fig. 5. The i-f receiver and preamplifier. The wideband VHF Engineering receiver consists of the rf module (second from left), two 100 kHz 10.7 MHz i-f amplifiers, and an audio amplifier. The pot is the volume control. No squelch is used on my system. A converted OSCAR 30 MHz preamp is also illustrated. The rewound toroid matches the 200 Ohm Gunnplexer mixer diode.

However, as mentioned earlier, afc is required on a narrowband system. Afc can be produced by comparing the i-f to a standard, and using the error voltage to tune the varactor. Additional details are provided in the Microwave Associates bulletin, number 7624A.

A wide i-f passband decreases effective range. However, the drift problem is eliminated. Range with an i-f passband of 100 kHz is about 50 miles. As indicated earlier, a commercial FM broadcast receiver can be used in experimental systems. The bandwidth of commercial FM broadcasting is 150 kHz; thus the commercial receiver is a viable i-f system. If used, the broadcast receiver should have a good front end. Provision should be made to match the receiver's input to the Gunnplexer mixer diode.

My goal was to construct a simple i-f receiver that would perform in an experimental system. I also wanted to use available parts around the shack. Let's see . . . an FM receiver, battery operated, simple? My first thought was an unused VHF Engineering receiver once used for 2m experiments. The only real problems were that the i-f was 10.7 MHz, and narrowband at that! I needed a 30 MHz i-f with a bandpass of 100 kHz. The first problem was solved by building a converter from International Crystal modules. This scheme used an International OF-1 oscillator with an inexpensive OX crystal oscillator, and an MXX-1 mixer module. The EX crystal provides injection at 19.3 MHz, thus matching a 10.7 i-f when 30 MHz is present. The only item purchased was the EX crystal.

If you try this technique, increase the link coil on the MXX-1 several turns to match the Gunnplexer. The mixer must be mounted as close as possible to the mixer diode on top of the Gunnplexer. A short run of RG-174 coax couples the converter to the VHF Engineering receiver. The mixer and oscillator were powered by a 9 volt transistor battery. This system worked fairly well. However, the mixer is noisy, and is not sensitive enough to complement the Gunnplexer.

I decided to use a better converter in my system. VHF Engineering makes a 30 MHz receiver strip, called the RF-50. This receiver has an FET preamp, and can be tuned over a range of 30-50 MHz. Remember to wind the coils for the 30 MHz option! This rf module is then used with the VHF receiver, consisting of the IF-10.7, IF-455, and AS-1 audio module. If you order these strips from VHF Engineering, specify the "wideband" option. The wideband kit consists of 10.7 MHz transformers that replace the 455 kHz units normally used. The wideband option converts the double-conversion receiver to a wideband (100 kHz) single-conversion job, suitable for Gunnplexer use.

It is best to wideband your modules immediately. I had to convert mine, which was a messy, time-consuming job. All the old 455 i-f transformers had to be removed from the PC board – ugh! Fig. 5 details the completed i-f receiver, mounted on standard VHF Engineering rails.

Preamp Option

An additional problem exists when using the VHF receiver. The input impedance of the RF-50 is 50 Ohms, and the Gunnplexer diode impedance is 200 Ohms. A simple balun could be used to effect a match, or the input coil on the receiver could be rewound. In the interest of performance, I chose another tack. I just happened to have a small, low noise OSCAR 10 meter preamp available. This preamp has a broadband toroid as an input circuit. It was a simple matter to rewind the toroid to produce a 200 Ohm input impedance. This preamp is visible in Fig. 5. A preamp is *not* necessary. I used one because it was available. I think the best method of matching the mixer in a simple system is to modify the input coil on the RF-50. The system will work if a 200-50 Ohm mismatch is present – you won't even notice it in close range tests!

Putting It All Together

Since my system is experimental at this point, I did not mount all the components in a single enclosure. I coupled the mixer to the OSCAR preamp (Mode X?), and ran a piece of RG-58 from the preamp to the RF-50. A nine volt battery powers the preamp, while a 12 volt nicad is used for the VHF receiver. The Gunn oscillator requires regulated power at 10 volts. I derived this voltage by using a National LM317 three terminal regulator (Fig. 6). This regulator requires an input voltage at least 2 volts higher than the regulated output. I built a battery producing about 16 volts from old AA nicad cells. Remember that the Gunn diode draws considerable current, and carbon cells probably won't last during experiments. Fig. 2 is a block diagram of the system. The voltage divider is constructed from a 10k pot and two 10k

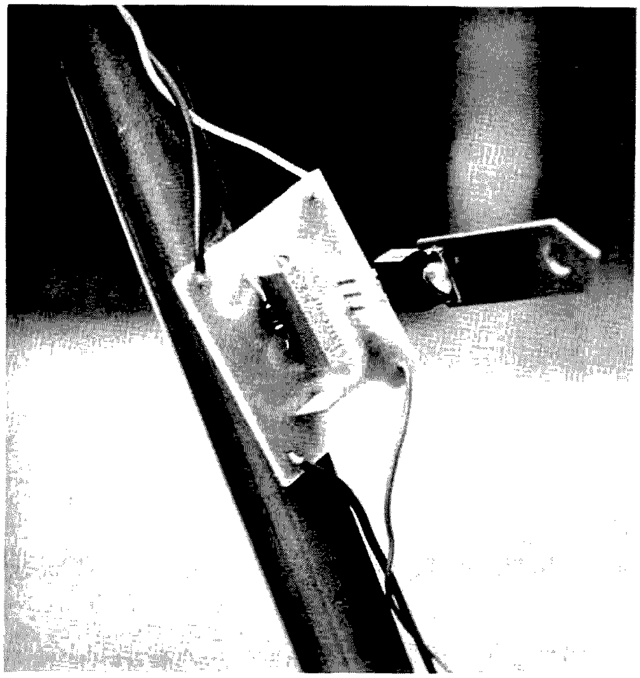

Fig. 6. The Gunn oscillator voltage regulator. A National LM-317 variable regulator, set for 10 volts, is used. The PC board and resistor are part of an evaluation device from National Semiconductor. The regulator is mounted on a leg of the tripod in my experimental system.

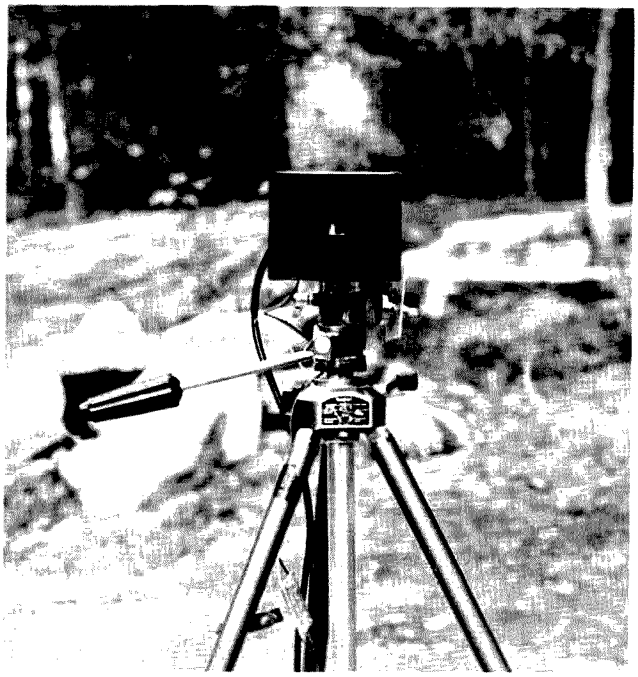

Fig. 7. Not a Martian, but a Gunnplexer transceiver rf head. The i-f amplifier and power supply is at the base of the tripod. Two transceivers should be separated by 25-50 feet for initial test. Ultimate range is 50 miles with this system.

resistors in series with a 9 volt battery. The varactor bias is developed at the slider. The negative side of both the Gunn supply and bias supply should be connected to the body of the Gunnplexer. I mounted the Gunnplexers to standard photo tripods by making a simple mount out of copper flashing. Drill two ¼" holes in a 2" piece of flashing to line up with the bottom screws holding the Gunn baseplate to the Gunnplexer body. Bend the flashing around the bottom of the Gunnplexer, and sweat-solder a ¼" nut to the flashing. The nut will mate with the bolt built into most tripods.

Tuning Up

My system consists of two Gunn transceivers. When initially checking your system, position the two transceivers about 50 feet apart, facing each other. Adjust the bias supply so that about 4.5 volts is present at the varactor diode on each transceiver. Apply Gunn voltage. If a 0-500 mA meter is available, check current drain. The Gunn diodes should draw about 225 mA at 10 volts. This is not standard; different diodes draw slightly different currents. Adjust the varactor voltage divider on *one* transceiver. Tune very carefully until the receiver quiets – there, you're on 10.25 GHz! This system is full duplex – you will hear yourself in your receiver when talking. Occasional tweaking of the bias will be required to keep the transceivers locked ... however, once they are temperature stabilized, remarkable stability will be noted with a 100 kHz i-f.

At this point, you will probably begin experimenting with the transceivers. Try reflecting the signal around a 90 degree corner with aluminum foil. I won't even attempt to suggest experiments and applications – if you've followed me this far and built a system, you don't need my prodding! However, I will be continuing this series with practical experiments and applications involving radar. Don't keep us in the dark, however. I would appreciate hearing from anyone experimenting with Gunnplexers and will welcome articles featuring the device. Write me, in care of *73*.

A Word of Caution

If you have been following my editorial in *73*, what follows will be repetitive. Microwaves are potentially dangerous. Do not needlessly expose yourself to the microwaves generated by the Gunnplexers. Although the level is very low, why take a chance? Opinion concerning microwaves varies, but one fact is certain: Microwave radiation can damage the tissues of the eye. The effects are cumulative, so treat the Gunnplexer with the same respect afforded a high voltage plate supply. *Never* look into the horn of an operating microwave transmitter. Avoid looking at the mixer diode in a Gunnplexer while it is operating; if you see it you're being exposed. I personally do not stand in front of a Gunnplexer at distances under 25 feet. When operating indoors, I use a cheap police radar detector to monitor the Gunnplexer – it's too easy to leave the Gunn supply connected ... no noise is generated by a Gunn diode! Happy experimenting!

Interesting effects are liable to occur if you operate your Gunn transceiver mobile in a police radar zone. Their radar is broadband by nature, and will respond to your legal microwave transmission, exactly as my detector responds to "out of band" signals from the Gunnplexer. Have a copy of your amateur ticket available – I would hate to learn that your transceiver was impounded. Newfangled devices, what's the world coming to?

I would like to thank Dana Atchley, Jr. of Microwave Associates and Bob Brown of VHF Engineering for their advice and suggestions. ■

Home Brew Tilt-Over

-- the water pipe special

Max Holland W4MEA
Hiwassee College
Madisonville TN 37354

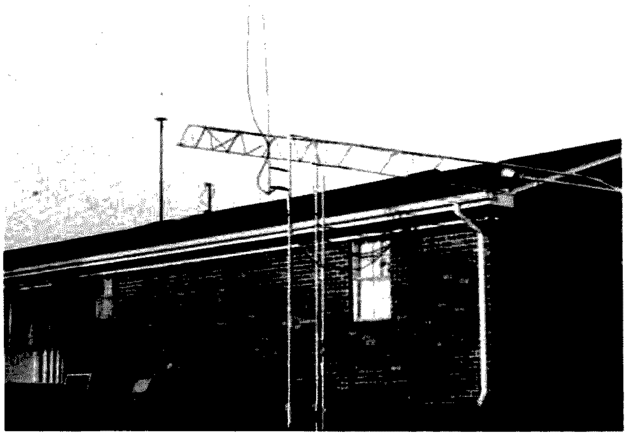
A primary disadvantage of antenna work is the need to constantly climb up and down the tower. A tilt-over tower is very desirable; however, the expense is often prohibitive. If a person has access to a fairly heavy-duty welder and is interested in building his own tower, this design seems to be a fairly good compromise between height and convenience. The very tall towers have such extreme weight when tilted over that they require some heavy-duty cable and construction.

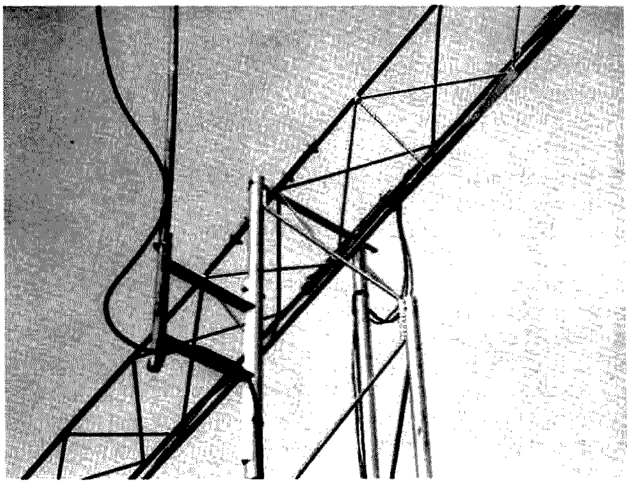
This tilt-over tower was constructed using galvanized water pipe and reinforcing bars (called "rebars") purchased at the local junk yard. The total cost, not counting labor and the welding expenses, was approximately $100. The dimensions given in the accompanying diagram will be of great help in getting started.

Basically, the construction consists of determining the dimensions of the base section and making up two plywood forms with the holes drilled in the shape of a triangle. One and one quarter inch water pipe is put in the holes, and the rebars are cut and tack-welded in place. The final welding is done after the necessary alignment has been checked.

The base section calls for one cubic yard of concrete. The hole was dug 3 feet by 3 feet by 3 feet. Gravel was put in the bottom of the hole, and the legs of the lower section were put down into the gravel to allow for the drainage of any accumulated water. Wires were attached to the legs of the tower, and additional rebars were placed in the sides of the holes at this time.

After the concrete has set, the top or tilt-over section of the tower is hoisted into position, using the cable and winch attached to the tower. After the top is placed in position, a 5/8 inch diameter bar is required. Then the cable and the winch can be moved to the end of the tilt-over section of the tower, and the tower can be pulled up into a vertical position. A





yoke, in which the tilt-over section of the tower lies, is then made, secured by at least 6 stainless steel clamps (the kind used on automobile water hoses). A more suitable method of attachment may be used; however, this method provided good side clearance between the tilt-over section and the base section. After two years of use, it seems to be more than adequate for the weight involved.

The total height of the tower is around 35 feet. The top section was made out of conduit tubing, for the additional benefit of light weight. Three quarter inch conduit fits over the one half inch galvanized pipe used for the tilt-over section. Once again, rebars were put into the tower section in triangular shapes for additional strength where the tower bends. Additional rebars and reinforcement were used to keep the tower from collapsing at that point.

A metal plate was attached inside the tower and a CDR Model AR 22 rotator was mounted. A Model 44 or Ham-M rotator could be mounted in the space, but the holes for the mounting plate would have to be changed accordingly. The pipe upon which the antenna mounts is 1-1/4 inch aluminum with the topmost part being 1-1/8 inch aluminum tubing.

The tower was given a coat of aluminum paint, and seems to be holding up fairly well after 2 years. The aluminum paint will probably last 3 or 4 years. The total time to paint the tower (considering all the small and minute parts) amounted to about 6 hours. Spray painting could be used if desired.

The winch is sold by Sears, Roebuck and Co. The cable is rated at about 1500 pounds.

As an additional safety precaution, when the antenna is in the vertical position, a heavy-duty chain and lock is wrapped around the legs of both sections. The triangular shape of the leg braces for the base of the tower discourages the climbing of the tower.

The feedline for the antenna can travel along the legs of the tower. There is enough clearance between the two sections to tape the coax cable directly to the tower. The bracket mounted on the side of the tower (see photo) is used to support a 10 foot long pole, which is used as a center support for an 80 meter wire dipole. ■

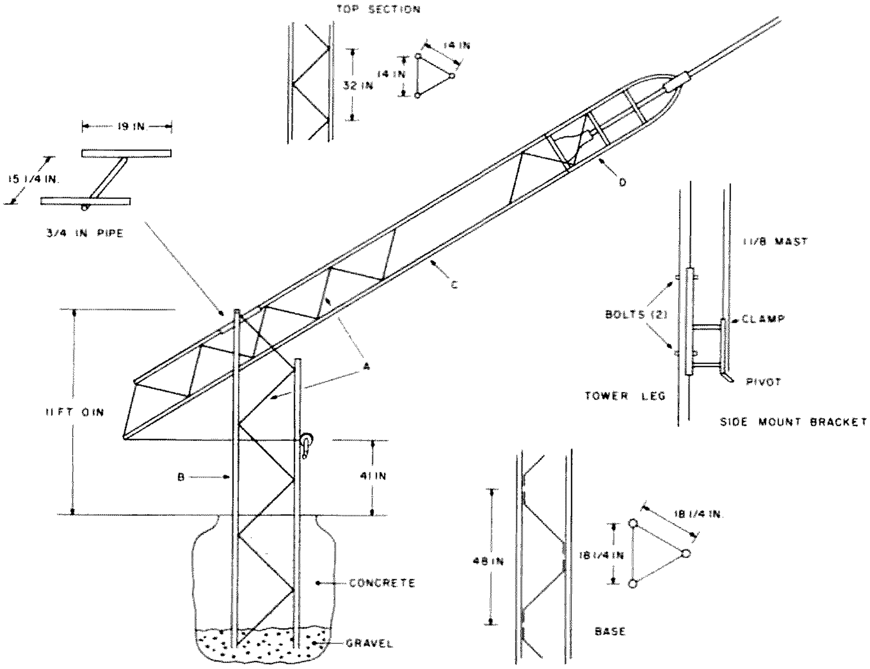


Fig. 1. A = 3/8" rebar. B = 1¼" galvanized pipe. C = ½" galvanized pipe. D = ¾" conduit tubing.

Minimize Feedline Loss

-- UHF buffs, front and center!

It has been pointed out on occasion, but not often nor emphatically enough, that the standing wave ratio (swr) as measured down in your cozy ham shack is not the same as the actual swr up at your antenna. The swr at the antenna will always be higher than what you measure it to be at the transmitter end. The reason that the swr is lower at the transmitter end is because of losses in the transmission line between transmitter and antenna. So, while it is undeniably nice to have a low swr at the transmitter, line losses are not exactly the most efficient way to go about it.

How do line losses lower the swr at the transmitter end and fool you into thinking that your antenna is a better match than it really is? Glad you asked. Here's the answer. That little swr meter atop your transmitter measures the reflected power relative to the forward power. The swr is proportional to the ratio of reflected to forward power, or more precisely:

$$\text{swr} = \frac{1 + \sqrt{\dfrac{\text{reflected power}}{\text{forward power}}}}{1 - \sqrt{\dfrac{\text{reflected power}}{\text{forward power}}}}$$

Unfortunately, the ratio of reflected to forward power which the swr meter sees down in the shack is not the same as that which the antenna sees. Because of the losses in the line, the forward power at the antenna is less than that leaving the transmitter, which is what the swr meter sees. What's more, the reflected power which the swr meter measures is less than the reflected power at the antenna, again, by the amount of loss in the line. This is because the reflected power travels backwards through the same lossy line from the antenna to the swr meter and transmitter. If you are algebraically inclined, you can see that in the equation for swr, the reflected power in the numerator of the square root terms is made lower by the line loss, while the forward power in the denominator of these same terms is made higher. Both effects cause the square root terms to be less, which results in the value of swr being lower. Thanks, or no thanks, to line loss, the swr at the transmitter end is lower than the actual swr of the antenna.

"So what," you say. Well, for those skeptics who may be sitting back reading this article after calling CQ for fifteen minutes straight with no replies, let me present an example of just how significant an effect this can be.

Consider a ham who operates on ten meters using 150 feet of RG58/U coax to feed his antenna. One night his antenna blows down, leaving the feedline dangling in thin air on his roof. The next morning, unaware of the disaster which befell his antenna, he sits down for a few hours of operation. Tuning up, he checks his swr meter. It reads about 2.1:1, a little worse, perhaps, than usual, but not too bad. It will do for now, or so he thinks. After an hour of fruitless CQing, he throws in the towel and goes out for a walk, tripping over his antenna on the front lawn. An extreme example, you think? Not at all. It has happened to me and I'll bet to many others.

The startling fact is that the swr at the antenna end of the feedline (where the antenna *used* to be) is infinite; all the power is reflected because there's nowhere else for it to go but back. Yet the swr meter in the shack reads 2.1:1. This clearly demonstrates the kind of difference line loss can cause between actual and apparent swr.

And that's not all the bad news. Remember that power reflected from the antenna (let's assume again that there *is* an antenna) is reduced by the effect of line losses as it travels back from the antenna towards the transmitter. This is lost power, just the same as power is lost in going forwards from the transmitter to the antenna. But this reflected power loss is a function of how much power is reflected in the first place. Or, put another way, the additional power loss (in the reflected wave) is a function of the antenna swr. The higher the antenna swr, and the higher the rated attenuation of the feedline, the more the additional loss will be.

So now that you are a believer, you will want to know what your antenna swr *really* is, and how much additional power loss that swr is causing in your line. Thanks to a friendly computer, the answer is easily found. Just look it up in Table 2. To use Table 2, all you need to know is the *rated* attenuation for the type and length of feedline you are using, as well as the reading of your swr meter at the transmitter. The rated attenuation of feedlines is available in manufacturers' literature and in the various radio handbooks. Don't be surprised if you find the values from different sources differing by up to a dB or so. But so you don't have to go searching, I've summarized the rated attenuation per

	Type of Cable			
Band	**RG58A/U**	**RG59B/U**	**RG8A/U**	**RG11A/U**

Table 2. Note that for rated line loss above 2 dB, the measured swr at the transmitter end will never go very high, even with very large swr at the antenna.

An example will serve to illustrate the proper use of these tables.

Let's say that you have one of the popular 100 Watt output SSB transceivers feeding a trap tribander through about 150 feet of RG58A/U coax. You tuned the antenna for the CW end of the bands because that's where you spend most of your operating time. At your favorite frequency of 14.026 MHz, the swr meter sitting atop the rig reads about 1.2. On occasion, you QSY up the band to 14.335 MHz to keep a weekend sked there and add to the QRM. Up here in the high end of the phone band, your swr meter reads about 2.0. Darn good, you think. But let's see if it is.

From Table 1, the loss per hundred feet of RG58A/U is 1.9 dB in the 20 meter band. Now, since your line is 150 feet long, its rated attenuation will be (150 feet/100 feet) x 1.9 dB = 2.85 dB. Going to Table 2, we find that line which has a third column entry ("Rated Line Loss in dB") closest to 2.85 dB (it will be 3.0 dB), *and* a first column entry ("Measured swr at Transmitter") closest to the 2.0 your meter reads (it will be 2.0). Finding this line, the actual swr at the antenna is given in the second column ("Actual Antenna swr") and we note that it is 4.97, almost 5 to 1! A lot higher than you thought, isn't it? The value in the fourth column ("Actual Overall Loss in dB") gives you just what it says, the real losses in your line in dB, including the effects of the actual swr and losses in reflected power.

This is 5.03 dB. *Surprise!* And now for the final shocker. The last or fifth column, labelled "Overall Efficiency of Line," reads 31.4%. This just about says it all in a single figure, and possibly explains why you have such a tough time completing that sked. Of the 100 Watts your transmitter is putting into the lines, only 31.4 Watts is actually delivered to the antenna for radiation. You've been working QRP and you didn't even know it.

Now you should be prepared to check out the real facts of life in your own antenna system. I hope it won't turn out too badly for you, but I'll lay odds that it will be worse than you thought it was. Well, back to the drawing board.

Just what can you do to improve things? A full answer is far beyond the scope of this article. But a few things you can do would have to start with getting *low loss* feedline. Every tenth of a dB of loss hurts you two ways – forward power loss and reflected power loss. No single factor will improve your overall efficiency as much as using the lowest loss feedline feasible. That's one reason why open-wire line sometimes works so well. It is *extremely* low loss. After you have gotten your line losses down as low as your finances will permit (lower loss, bigger bucks), then work on reducing the swr *at the antenna* feedpoint, by tuning, matching, trimming, or whatever is appropriate to your particular antenna. After that, there's always a matchbox or antenna tuner as a new addition at the transmitter end. Now understand this very clearly: A matchbox at the transmitter end will not in any way reduce the kind of transmission line losses discussed in this article, except over that short portion of line connecting the matchbox to the transmitter. A matchbox will, however, provide a very low swr to the transmitter which will enable it to put out all the power it was designed to, even though we know some will be lost in the line. Without a matchbox, it is quite possible that the transmitter will be unable to put out its full rated power in the first place. Incidentally, it is probably worth mentioning that the "Measured swr at Transmitter" in Table 2 and in the discussion implies that it is measured on the antenna side of any matchbox, if one is used. This should be obvious, but probably won't be to everyone. The swr at the transmitter side of a matchbox is normally 1.0 if the matchbox is tuned correctly, but something quite higher at the antenna side. So if you already have a matchbox and are going to make these measurements, be sure to move the swr meter to the antenna side, after first tuning the matchbox for minimum swr going into the transmitter.

There is no one big secret to a stand-out signal, just a lot of small ones. Now some of them aren't secret any more. ■

How About 6 FM?

- - it's easy

with a modified HE-50

Allan S. Joffe W3KBM
1005 Twining Road
Dresher PA 19025

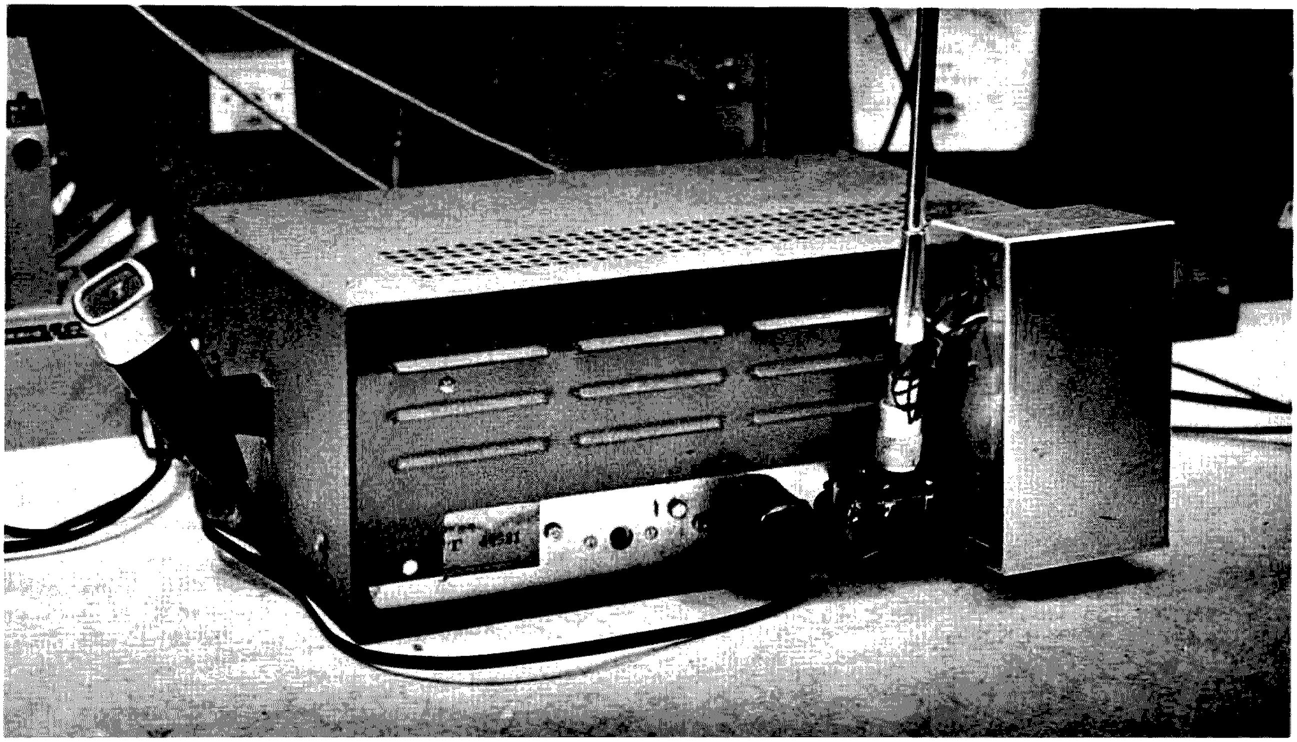
WR3ABE is a fine, well-managed six meter FM repeater in our area. I have had access to it on a mobile basis for some time, but never had gotten around to installing a base station at the QTH. The search for such a facility had been an off again, on again type of romance until fate intervened. W3GHH announced that his Lafayette HE-50, a little old-time ten meter transceiver, was available if anyone had a use for it. Examination of the contents of the box and its schematic showed great promise for a good six meter conversion. The receiver is single conversion with an rf amplifier, two stages of 1650 kHz i-f, a good noise limiter, plus capability of operating on either the 110 volt line or on 12 volts dc.

The transmitter consisted of two tubes, a 6EA8, and a 2E26 in the final. The triode section of the 6EA8 worked as an oscillator/doubler. The pentode section of the 6EA8 worked as a second doubler, and the 2E26 worked straight through on ten meters.

The transmitter conversion consisted of getting six meter output on the repeater frequency using 8 MHz crystals. Then the AM modulation had to be removed from the final and an FM modulator installed. The first doubler coil was pruned so the stage would now be a tripler. Thus its output was in the 24 MHz area. The pentode doubler was left a doubler, but its tank circuit was altered so it would tune to six meters. The same operation was performed on the final tank coil. Thanks to a grid dip meter, this operation took about 3/4 of an hour, and the transmitter was putting about five Watts out on six meters. The normal dc input to the final is about 12 Watts. The rf conversion included clipping and discarding a built-in TVI harmonic trap which had been connected from output of the pi network to ground. With some five Watts of rf available, it was time to attend to the change in modulation.

Fig. 1 shows the final form of the FM modulator. The AM modulation was divorced from the final by the simple expedient of changing the B+ feed to the final so that it got no audio. The 5k 5 W resistor was added as a load across the modulator output to replace the class C rf load that had

Photos by WA3PTC



been removed. A small audio transformer with a 20,000 Ohm primary and a 600 Ohm secondary was fed from the old modulator through a 0.01 uF capacitor to isolate the B+ from the primary. The varicap network was wired across the 600 Ohm secondary and coupled across the crystal. A 45 pF trimmer was put in series with the crystal to put me on the nose with the repeater input frequency. There are those who will shudder at the lack of frills in the modulator, e.g., no dc bias on the varicap, etc., but the proof of the audio is in the hearing and reports have been uniformly favorable.

With the transmitter so nicely under control, attention was paid to the receiver. The lineup consisted of an rf stage, a converter, two i-f stages, and the usual functions after this point. The initial thought was to convert from six to ten meters using an external converter. Then, second thoughts came to bear as the front end was examined more closely. Fig. 2 shows the first several stages of the receiver. The thought that came through was to examine the possibility of making the rf amplifier a converter, add a crystal-controlled local oscillator for injection, and leave the rest of the receiver untouched.

A six meter tuned circuit was put in the grid circuit and dipped to frequency. The bench signal generator was used as an injection oscillator, with very satisfying results. An order went out for a 23.64 MHz crystal, which produced the hardest part of any building or conversion . . . waiting for the mail! Naturally, being human and subject to impatience, I put the thing on the air for an initial contact through the repeater. With the assistance of WA3RMA, I overcame such obstacles as a varicap that decided to head west, an intermittent mike cable, and other standard assorted griefs. If the signal generator that I was using as the converter injection oscillator could have been condensed, I might have been tempted to call it a day and button up the case. As usual, though, reason did prevail and the wait for the crystal began.

The received audio from the repeater is so good by merely using slope detection that all thoughts of installing a conventional FM detector vanished. This may, in part, be due to the excellent rf signal that the repeater puts into my QTH. In any event, armchair copy exists here without any detector changes.

As the crystal-controlled

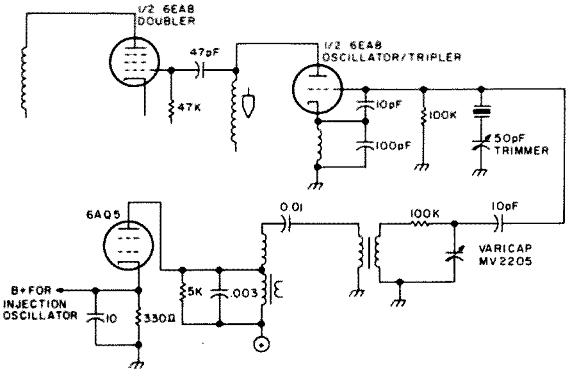


Fig. 1.

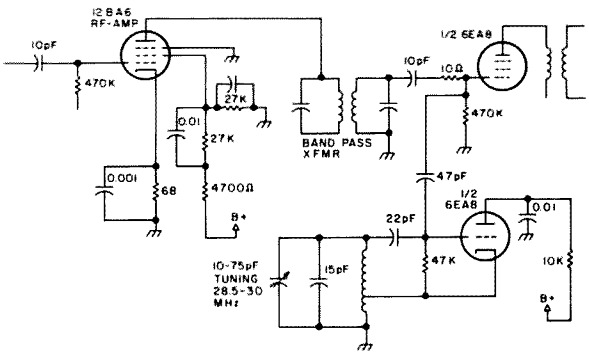

Fig. 2.

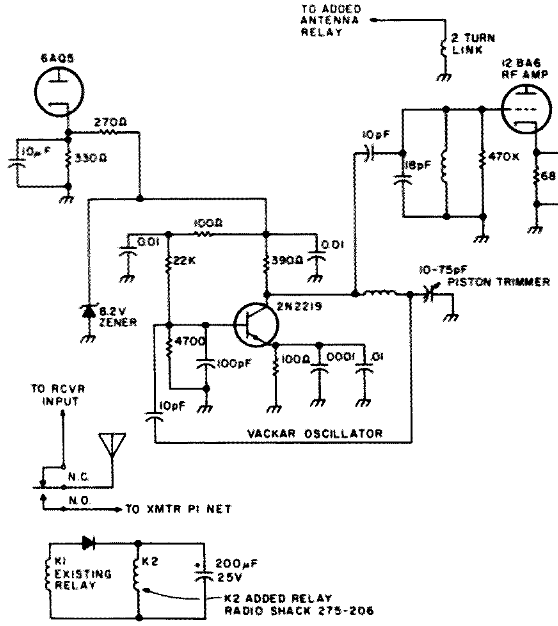

Fig. 3.

injection oscillator was going to be solid state, a source of low voltage was needed. The cathode bias resistor of the 6AQ5 proved to be a handy source of plus 10 volts, solving this problem.

Nothing could spoil this fine forward progress except the mailman, or more precisely, the mail person, as he is really a she. The postcard was from the Great American Pool Table and Quartz Crystal Company. It said: "Dear Cur: Your crystal will be along in about eight weeks."

Not only were they making me wait two months for the crystal I wanted yesterday, but they also had included a finely drawn character analysis in the message.

Fortunately, I had heard of Mr. Vackar and his driftless, easy-to-roll VFO. This little item (Fig. 3) worked extremely well, and was installed in a minibox on the rear of the transceiver. The design information was abstracted from a fine article in the February, 1968, issue of *Electronic Engineer*, written by Gary Blake Jordan. A rough check of stability showed a drift of about 100 Hz over a period of about three hours after turn-on. There is plenty of room inside the transceiver for this unit, *but* there is a hostile tube-induced heat problem that I wished to avoid — hence the external mounting site.

The only other item of business was to install an antenna transfer relay. You might well ask, if it is already a transceiver, why do you have to install one of these? The answer is simple. The original design had the transmitter output and the receiver input tied together as shown in Fig. 4. It worked fine on 10 meters, but I could not get it to behave on 6 meters — hence the added relay.

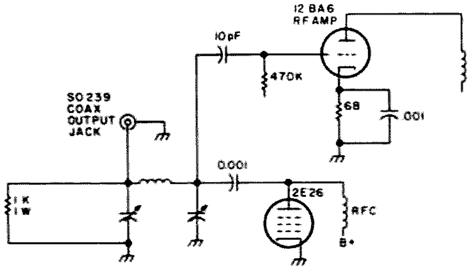

Fig. 4.

Afterthoughts

The nice part about a globe like the 12BA6, in contrast to a transistor, is that it has three possible ports of entry for the injection oscillator. I tried all three, cathode, control grid and suppressor grid. The control grid injection seemed to give the greatest gain, and thus was used in the finished conversion.

The original press-to-talk relay is actually an ac relay which has a resistor thrown in series with it when the unit is used on 12 volts dc for portable use. This explains why the diode and the filter cap appear along with the added relay as shown in Fig. 3.

The FM modulator deserves a special note. Perhaps due to personal preference and how the gods smile at the time, I have always had good luck with the varicap modulator *when* it gets its audio from a relatively low impedance winding of a transformer. For some delightful reason, the diode does not seem to care which end is up, and there is no polarity problem. It also seems to be perfectly happy without any obvious dc bias, so why fight fortune?

The vertical antenna shown mounted on the rear of the unit is OK for short hauls, but there is nothing that can take the place of a good skyhook as high up as reason will allow.

There are many similar units that have fallen into disuse as the times change, just waiting to be rescued and put to good use. Try it — you'll like it. ■

Ham Help

I would appreciate your technical help on an antenna problem. Because I live in an apartment, I decided to go with a mobile antenna and operate from my car. I bought a Hustler mobile antenna and a 40 meter resonator. Much to my surprise, it worked quite well. Later, of course, I wanted to at least listen to the radio inside my apartment. I bought an extra mobile mount and assembled the antenna, adding a single wire to the mount — the length of the car. The reception was still very good. Now the problem. I tuned up the transceiver (a Kenwood TS-520) and found a 1 to 1.3 swr. Can I go ahead and transmit and not cause harm to my transceiver? I would rather not go to the expense of a transmatch unless really necessary. If this antenna system will work, where did I go right?

William Day WB0VTB
3420 Lakeside Manor Apts.
Iowa City IA 52240

I am interested in a simple tube converter circuit to observe received signals on my general purpose scope, which has a horizontal sweep range of 250 kHz and a transceiver i-f of 3180 kHz. Transceiver is a Yaesu 101-B. General purpose scope is Dumont type 304-AR.

Bill Massey WB6SSQ
1505 Lynton Avenue
Wilmington CA 90744

I have been trying to locate a source that has Gunn diodes for the 10 GHz range to use in an oscillator for microwave bench experiments, as in *73*, March, 1974, page 33. I have an oscillator cavity, once part of an intruder alarm, but the Gunn diode is gone. It seems similar to what Microwave Associates calls style 30 case. I have had no luck calling companies for a possible replacement. Might any of your readers be able to supply an exotic device such as this at a reasonable price for 1-2 units? Thank you.

Merek Geiger
111 Hendrickson Ave.
N. Merrick NY 11566

Having recently upgraded my license, I have begun thinking about other forms of ham radio. I would like to put a 2 meter antenna on my Cessna Skyhawk, but so far I have not been able to find one which will pass FAA requirements and not cost several hundred dollars. Any help in solving this problem would be appreciated.

W.A.S. -- Easily!

-- catching the last few

Dave Waterman W7FGD
1810 E. Terrace Way
Kelso WA 98626

Regardless of whether you have had your ticket for quite a while now or you are just getting on the air for the first time, I would like to present you with a challenge. The purpose of this article is to give you some hints and techniques to enable you to work a ham in every state of the United States and to get a QSL card back from him.

The ARRL has awarded over 25,000 Worked All States certificates to hams all over the world, and you can get one, too! It requires a little patience, a lot of listening on the bands, and a bit of work. Oh, come on now! You're not afraid of a little work!

A WAS award is a lovely certificate to frame and hang on the wall of your shack, a fine conversation piece to show friends and family, and working for it will sharpen your operating skills. The ARRL offers one as do several other organizations and magazines.

But how do I work all 50 states? How can it possibly be done on the crowded Novice bands? How do I get that elusive Delaware contact? Or Wyoming? Or South Dakota?

Hopefully, we will answer these questions for you and get you started down the road to a WAS award.

Starting Off

First you must get yourself organized for the task. Take a sheet of lined paper and list all 50 of the states on it in two vertical columns, one down the left margin, and one down the center. Most lined paper has 25 lines on it, so you can get half the states in each column. This is to be a check-off sheet for you to mark your progress. Each time you get a QSL from a new state, put a check beside that state on your list. As time goes by, this list may become dog-eared, so I would suggest a clear plastic cover for it to protect it. Keep this list at your operating desk where it can be seen at a glance. This list serves several purposes. It not only shows the states you've worked, but shows you the states you still need. If you hear a station give his QTH, a quick look at the list will tell you if you need him. Don't rely on your memory – use the list. Another thing this list does is help keep you on your toes and very aware of the states that you need.

Antennas

OK! You've got your check-off list prepared. Now what? In your studies to get an amateur license and in almost all literature that you've come across concerning operating, you've been told time and time again that your antenna is the most important part of your station. I'm sorry to do this to you, but we're going to talk about this subject again for the million and first time, because it is so very, very important. You absolutely *must* get the best antenna you can for the bands which you choose to operate. If you have an oversized lot, lots of trees for wire arrays, neighbors who will let a few wires spill over onto their property, pat yourself on the back and light up a cigar; you're a lucky fellow. (I fall into this select category and realize how very fortunate I am.) Most hams are not so fortunate, and we're going to assume that you're one of them.

For the purpose of this article, we will assume that you run 100 Watts and use a dipole or an inverted vee antenna, which is capable of operation on 80, 40, and 15 meters. Ten meters is so sporadic these days we will disregard it. I may be doing a disservice to this band, but you can't rely on it right now.

Now our next step is to trot outside and take a close look at that antenna of yours. Is there any possible way to put up a full wave loop or Delta loop for 40 or 80? If so, do so! If not, can you raise that dipole any higher? How about adding a sloping dipole off one or both ends of its supports? Slopers are very effective antennas, and also hear very well. Info on these antennas can be found in the many antenna books available either by mail or from your local ham store. (You do have a local ham store?)

You say you can't do a thing different, huh! OK, make sure your antenna is radiating in the direction of a maximum number of states.

A north-south radiating antenna in Southern California isn't going to do too well in the Eastern seaboard. Of course, power lines and TV antennas slue radiation some, but check to see which way your signal is going. If you have any questions about this, refer to the antenna books. What you want is as low an angle of radiation as you can get, in the desired direction.

Now, how about the coax (or whatever feedline)? Check your connection to the antenna. Is it corroded? Just one hard rain can seriously lower signal levels if you haven't weatherproofed your feedline connection to your antenna. A W2AU balun*, or one similar, is ideal for this weatherproofing and eliminating feedline radiation with coax. Assuming your antenna is satisfactory, now look at your ground system. Ground system, not a ground wire! You need a ground wire going out of your shack to a buried cold water pipe (if at all possible). In *addition* to this, you need a separate counterpoise for each band you operate on. Check the antenna books again for info on these. They're simply lengths of wire cut to various lengths for each band — simple to install and effective in boosting your transmitted signal.

Having maximized antenna and ground systems, we now turn to take a look at your shack. Do you use an antenna tuner and swr meter in your feedline? You say you don't! Oh, come on, I'm trying to help you, not start a fight, but really now!

An antenna tuner and swr meter are essential for minimizing losses, especially if you're trying to utilize that dipole of yours on 15 meters. There are many plans for building tuners in past ham magazines (*73* has had several). You can build one for next to nothing, with a large coil and a wide spaced tuning capacitor from an old AM radio. Please get a tuner if you don't have one already. Some day you'll thank me.

If you operate a transceiver with VOX, you need not worry about a transmit-receive switch. If you run separate receiver and transmitter, you will. (Don't try and hide that knife switch you use. I can see the guilty look on your face.) If you have been using a separate switch to go from transmit to receive, carefully disconnect it, hold it firmly in your right hand, and throw it as far as you can. Now build, buy, beg, trade, or steal some sort of a T-R switch to use. It's hard enough to get that elusive Rhode Island contact when his signal is 339, the QRM is 599, and the QRN is 40 over. You don't need to be flipping switches while that is going on. It will be plenty hard enough as it is. This is the electronic age and you're a member of the brotherhood of ham radio operators. Use your electrical knowledge and get rid of that old knife switch.

As for the swr meter, they're available at every CB store, ham emporium, and from every gypsy on the street in every city of the US (and by mail order).

We have upgraded all the hardware now, except for one item. There is still one link in your communications system we need to look at. That's you!

As long as there are different people in the world, there are going to be different operating techniques. What this is really boiling down to is the psychology of what makes you — you. But before we get into this very deeply, let's look at the different ways there are to work all states. You mean there's more than one? Yes! Actually there are three ways, all separate and distinct, in which a ham can achieve WAS. The first is to be a contestor. That is, operate in the large number of contests that occur each year. Successful contestors usually have years of experience and large numbers of them work all states every contest they enter. They have a high degree of competitiveness and a great pride in their gear, antennas, and especially their skill. They are after contacts and multipliers; they want all the stations they can work, the more, the better. They seldom rag chew. They are above our level of operation and they're not reading this article anyway, so we'll forget them.

The second way to work all states is to get on the air for an hour a night, every now and then, and possibly two or three on the weekends. Chat for hours at a time, long and lengthy, about the height of the tides and the phase of the moon with every station that answers your CQ. Sooner or later, this operator will obtain a WAS certificate by chance. It is entirely possible, however, that the Sphinx will have turned to dust, the Rockies will be a desert, and everyone will have moved to Andromeda by then.

The third way, and the one that you need to take, is to sit down with some sort of an organized plan, listen to the stations that are on the air, find the ones you need, and slowly check off the blank spaces on your check-off list as you move closer and closer to your goal. Here is where the psychology angle comes in. You need to ask yourself, what kind of person am I? Do I like to talk? Do I talk, maybe too much? If so, it could be that while you're chatting away for 45 minutes to Ralph in the next county, that Maine station 3 kHz down from you that you didn't even know was on the band, has worked twenty stations and went QRT for the night. Now please don't get me wrong. I'm not against rag chewing. As a matter of fact, I'm very much for it. I

*Brand name.

dislike formalized QSOs and have made many, many great QSOs with interesting people. But a serious fisherman, when he goes fishing, is after fish. If the fish aren't biting and are not to be found, then they sit back and watch the sun set. You can very easily spend far too much time in a QSO during prime band hours if you like to chat. You need to look at yourself and the way you operate and ask yourself what you get out of ham radio. Are you operating correctly? Are you achieving what you want? If you love to chat and enjoy people, that's great. If you find it hard to open up to strangers, shorter QSOs will be your norm and you will log more stations in a given time than one who is more long-winded. Maybe you're not going after stations with enough aggression. If you're really serious about this WAS award, go after it with gusto. Keep your QSOs short and be alert for the next fellow down the line, at least during prime band hours.

Enough Talk – Let's Get At It

OK, we're starting off. Let's quickly look at our bands. 15 meters is usually a daytime band, with some seasonal variations to different parts of the country. Check it out. It can be your most valuable band when it's open. Your dipole and 100 Watts won't make you a powerhouse, but many stations that you work will be using beams and that will help. 15 meters is a fun band and you have a little elbow room to move in. Favor it as much as possible. It can get those states on the opposite seaboard that you need. It can also get most everything in between.

40 meters begins to come in strong during late afternoon (out here in Washington, anyway!) and will drop out in middle evening. 40 also has seasonal variations. Winter is best. Summer brings static, but hang in there if you can. There is still a lot of action if your eardrums can take it. 40 will get you the midwest and the south easily.

80 meters is best in early to late evening. Summer brings much static, too. Keep in mind that we are being very general about all this and that sunspots and cold fronts and other factors can change things greatly. 80 will get you the adjacent states and midwest and south, too.

In your early quest for WAS, a lot of CQing can be beneficial. You need to work most every state. The states will come quickly and it will be great fun to watch the cards come in and check off the states on your list. But, as time goes by, and your check-off sheet gains marks, new states will get harder and harder to come by. Here is where the real work will begin. (Remember, I never said it would be easy!)

Now you're going to have to change your operating habits a bit. You're going to have to listen more and be more selective in the stations you work. After your twenty-fifth 6-land QSL, you really won't have to work very many more for a while now, will you? In this respect, the guys in California have it rough, but there's nothing to be done about it. Just grit your teeth, California, and carry on.

Call areas will begin to slowly fill in. When you work all the zero-land states, forget them and move on to the others.

In order to get those remaining states, you're going to have to *listen*. Also, I would recommend a couple of techniques that have helped me. Buy a brand new *Callbook*. (Gulp – I know what they cost, but you're going to need it.) Practice using that book on calls that you hear on the air. Practice to the point that you can find a given call in about ten seconds. (Easy, huh? Just try it!) Now you have a valuable tool. In your tuning across the band, any station that you think you may need can be quickly looked up to find where he is, and not only him, but the guy he's talking to. I can hear you complaining about this from here. But look, you have doubled your chances to find those missing states you need. You need not now wait for him to give his QTH – look him up quickly. As you progress toward your goal, you will come to appreciate this technique.

Moving Right Along

OK. We have progressed along. You're spending more and more time now listening to the bands. You're learning how to fight the QRM and pick out the weak signals. You are looking for weak signals, aren't you? You don't expect that KH6 to come in 599 in New York, do you? He's probably going to be a 339, if that. You're going to have to listen for the weak ones and be very alert. Here you're going to suffer from the QRM problems on the Novice bands. There's a lot of you guys out there and you're all trying to work each other. It's only natural that the first time you hear that KL7 you need so badly, half the world is going to want him, too.

Audio filters, crystal filters, or just anything that will increase your selectivity is going to be a real asset to you.

If you find that the station you need is being called by a zillion other guys, there are two things you can do (three, if you consider quitting, but I'm assuming you've got gusto!). The first is to join the pack and have at him. For this you will need patience and perseverance. Be of stout heart and don't give up if you need him, even after the tenth time you called him and he went back to someone else. Or the twentieth. If he just won't come back to you, try tuning off his frequency just a little. Maybe there are so many people calling him that he can't make your signal out. Timing is important here. You'll just have to face a few of these and you'll learn fast. But there is another course of action left to you in a pileup. Be cagey! If the band is open to KL7-land and everyone is after one guy, maybe there's another KL7 down band a ways. Or maybe something just as juicy. If you hear a big pileup, check down band. When all the cats are out chasing a rat, the mice are left to play.

With everyone else after the same station, QRM drops down band and weak signals come through. In actual practice, on our crowded Novice bands, this situation would probably never happen. I can't really imagine every station in the band all on one frequency after one station. On twenty meters, yes, that happens; on the Novice bands, probably not. But I wanted to get the point across to you. You're going to have to be alert and think.

Now, let's say we've progressed further. Time has gone by and by spending more and more time on the air, and patiently listening, looking up calls in your book, and working the ones that you needed, you've got down to the point where you need just a handful. Let's say you need six more. You've spent weeks and weeks, now turning into months and months, and you haven't heard any station in those states. You spend your evenings on 40 and 80. Your Saturdays and Sundays are spent on 15. You spend so much time on your radio that the forest service is proclaiming your lawn a national park. Your dog bites you when you come home from work. Your two year old daughter cries when she looks at you out of fear of a stranger. All this and still nothing. OK, here are some things you can do.

First, watch for the state QSO parties in the states that you need. Most states have QSO parties once a year.

Some combine several states into one party, but it's all the same thing. At these times, operators in these states are more active than usual and are looking for contacts. Another thing you can do is spread the word to your friends that you are desperate for these states and if they hear them on the air to give you a call. Four, six, or eight sets of ears are better than one. Here's another idea — get copies of *QST* and look up the listings each state SCM sends in each month. Find out what's going on in those states you need. Sometimes you can get a valuable clue as to when and where a club or special events station will be on the air. Also try your hand in operating in a contest. The best one for you is the Novice Roundup. Your chances of having an operator on in a needed state are improved. However, the increased QRM caused by the contest makes it harder to get through. Still, it's something to try.

Suppose none of this works. You're going around muttering. "What the hell's happened to Delaware anyway. Why don't they send a DXpedition there?" Your job is suffering. Your wife is threatening divorce. And still nothing.

Get on your ham friends again. Keep on them. Check with any DXers in the area, any you might faintly know, any you may have heard of. DXers, county hunters, and regional net men have friends all over the country. Maybe one of them can fix up a schedule and give you a hand with the contact.

If all is for nought, and you still need some states, here's what you do. First put an ad in the ham magazines requesting a sked with the states you need. If that's fruitless, as a last resort, look up in the ham magazines, contest winners in the states you need. If a man is a contest winner, he probably has a better than average rig and antenna setup, and probably is more skilled than most. Sit down and write him a letter explaining your plight and beg him for a schedule at his convenience. That should work if nothing else will. I would do it for you, and I think most other hams would also. This should be considered as a last, last, last resort only. It is an imposition on people's time and themselves, and should not be requested lightly.

With the techniques I've outlined, plus a lot of time on the air, you should be able to contact a ham in all 50 states. But we're not done yet. Contacting them and getting a QSL are two different matters.

A QSL card should be a representation of yourself. It's all the other guy will have to remember you by. It should be different from the run-of-the-mill cards, and, if at all possible, unique. I would recommend to you that you have some special cards printed up. I have included one of my own cards to show you what I mean. It's not that my card is so great, but it is different, and reflects my own personality. I am constantly getting comments about it — just get something different that reflects you. Don't you dare copy mine; just get something out of the ordinary that people will remember, a photo card if you want.

Now, when you have that special card of yours, you're going to have to do one more thing. Do you know what an SASE is? It stands for self-addressed stamped envelope. Use them. At today's postage prices, please don't expect someone in a far-off state to spend his own money to send you one of his cards. Many will, but many won't also.

If you use a distinctive QSL card, filled out properly, with a polite thank you and a line or two about yourself on the back, together with an SASE, I'll guarantee you a 95% return rate (excluding calamities at the Post Office).

Have I made it sound easy? Well, it's not! It's hard work and at times very frustrating. QRM will be your biggest problem. Remember, all you have to get is the RST reports both ways to have a valid QSO.

Summary

Let's summarize what we've covered:

1. To earn your WAS, you're going to have to make it your goal. That means work for it.
2. Make your check-off list.
3. Maximize your antenna and ground systems.
4. Use an antenna tuner and swr meter.
5. Get a T-R switch if you don't have one already.
6. Spend time on the air and listen for the states you need.
7. Get a *Callbook* and be able to use it quickly.
8. Plan your operating time to take greatest advantage of open bands (prime time).
9. Take advantage of special operating events or state QSO parties.
10. Be alert and keep thinking.
11. Listen for the weak ones.

Lastly, you're going to have to look at yourself and evaluate yourself a little. If you're having trouble getting those states, maybe it's something you're doing wrong. Change your operating habits. Get on the air at different times than you did before. Listen longer. Listen harder.

Well, I've done all I can do. Those 50 states are out there waiting for you. It's a great challenge and a fine reward to work all states. Good luck to you. ■

Tracking the Hamburglar

RIPPED OFF: Hallicrafters FPM300 MKII, s/n K530010, taken during break-in at home weekend of July 22, 1977. Bronx 52nd Police Precinct complaint no. 4565. Marty Greenbaum K2HTO, 3070 Hull Avenue, Bronx NY. Tel. (212) 231-3635.

SHANGHAIED: Heath Model 2021 handie-talkie with Model 201 touchtone pad built-in. Channel switch wired wrong in that channels 3, 4, and 5 go to crystal sockets 3, 2, and 1. Crystalled for 146.52 (ch. 3), 146.655 (ch. 4), and 146.94 (ch. 5). Stolen July 23, 1977 in Westport, Connecticut. S. W. Daskam K1POK, 38 Settlers Trail, Stamford CT 06903, (203) 329-0187.

LOOTED: Clegg FM27B, s/n 4647 was taken from my truck on August 11, 1977. Contact: K1ZUW, PO Box 102, Hudson NH 03051.

STOLEN: Clegg Mark III, 2 meter transceiver, serial 750,187 with .52-.52 from Dick Haskin W6KEC, 149 Mauna Loa Dr., Monrovia CA 91016.

STOLEN: Drake TR-4 SSB transceiver #16491, AC-3 power supply #18572, L-4B linear amplifier #1102, L-4PS power supply #1124, Hallicrafters SX-100 receiver #151257. These items were stolen in a break-in on April 27, 1977, at a local radio store in Louisville KY, where they were held on consignment for Ev Ballard WA4ACJ. Any information would be appreciated. Contact him collect at 502-451-8923 or 812-294-4819, or write 2438 Longest Ave., Louisville KY. (Also: Jefferson County Police Department, 502-588-2111.)

PURLOINED: Standard SRC 826M 2 meter FM transceiver, SN: 104207. Stolen on June 27, 1977 from Bill Myers WBØMCS, 942 E. Mississippi, Denver CO 80210, 303-777-3353. Has the following frequencies installed: 146.94-94, 52-52, 16-76, 34-94, 28-88, 88-88, 31-91, 148.01-01, 37-97, 19-79, 25-85, and 91-31. Has KØKGA scribed on receiver board. Receiver crystal board has been rebuilt. Channel 12 — 91-31 transmit is 450 cps. high in frequency; transmit trimmer for this channel is different from others.

RIPPED OFF: Icom IC-22A, s/n 9900 with 12 sets of crystals. Call and SS no. etched on back. Pete Jordan WA1AXK, 832 Temple Street, Whitman MA 02382.

Fool the Wire Wizard

-- a computer would have helped

Once upon a time, far, far away, there lived a wire wizard. The time was during World War II, and the place was on a US Navy warship. The wizard was an old Navy warrant officer with a nimble brain that was like a bear trap for facts of every description. One of his many skills was the ability to quickly give almost any information about soft drawn copper wire. For example: What is the resistance of 533 yards of 13 gauge wire? What is the cross section area of 33 gauge wire?

Mr. Steele, for that was his name, had a habit that just about drove me to distraction. He liked to bet on various matters. He always bet exactly $5.00, and he *never* lost a bet. When I would bet with him, he would tell me I was foolish because I knew he never lost. But, what the hell, I knew I was right *this* time (the *this* was for *every* time). But I wasn't, and he won again. One time he asked me who invented the audio amplifier. I replied, "Dr. Lee De Forest, who invented the audion (triode vacuum tube)."

"Nope," he said, "someone invented an audio amplifier before him."

"Who?" said I.

"Thomas Edison, that's who."

Aha! I had him. Old Tommy invented a passel of things, but not an audio amplifier. But I lost again because Edison invented a carbon microphone, and this was easily shown to be an audio amplifier. When the earpiece was placed over the mouthpiece of an old-fashioned country telephone, the thing would whistle on its own.

All of us pestered Mr. Steele to tell us how he could produce wire table facts so quickly, but he would never say. One day I asked him if he always bet when he knew he would win. "Absolutely," was his reply, "that is a cardinal principle with me." I then bet him $5.00 he could not teach me his wire table methods. Now he was boxed in. He thought about it a little, and then he told me he wouldn't bet because I might be too stupid to understand even though the method was simple. However, he offered to teach me on the sole condition that I would never tell it to anyone else on the ship. That particular ship has rusted on the bottom of the Pacific Ocean for more than 30 years now, so it seems fairly safe that I can now speak freely on the matter.

He told me to take a lined tablet and, on one of the lines about a third of the way down the page, to write the numbers 1, 10, 100, 1000, and 10000. He said that among these numbers was a fairly typical wire gauge which I was to select. It could only be ten gauge. One gauge is possible, but not common, while the other numbers are ridiculous as a wire size.

Mr. Steele then asked how the resistance of copper wire is given. The answer to this is in Ohms per 1000 feet, which takes care of the 1000 on the line of numbers. One can compute the cross section of a wire in circular mils by squaring the diameter in mils (a mil is 1/1000 of an inch). 1·1 = 1 is no help because it uses one value for two different data. We can't use 10·10 = 100 because 10 is already spoken for as the gauge number. The only other possibility is 100·100 = 10000 to give us a diameter of 100 mils and a cross section of 10000 circular mils. The 1 that remains is the resistance of one Ohm per 1000 feet.

There you have it for 10 gauge, soft drawn copper wire. One Ohm per 1000 feet, 100 mils diameter and 10000 circular mils cross section.

"Now," he said, "number

Resistance (Ohms)	Gauge	Diameter (mils)		Cross Section Area (C.M.)
.125	1	283		80000
.156	2	253		64000
.185	3	226		51200
.25	4	200		40000
.313	5	179		32000
.39	6	160		25600
.5	7	141		20000
.625	8	126		16000
.781	9	113		12800
1	10	100	1000	10000
1.25	11	89.4		8000
1.56	12	80		6400
2	13	70.7		5000
2.5	14	63.2		44000
3.13	15	56.6		3200
4	16	50		2500
5	17	44.7		2000
6.25	18	40		1600
8	19	35.4		1250
10	20	31.6		1000
12.5	21	28.3		800
16	22	25		625
20	23	22.4		500
25	24	20		400

Table 1. The characteristics of soft drawn copper wire as developed by the wire wizard.

upward and downward from the 10 for the wire size." So above the 10 in a column I placed 1 through 9, and below the 10 I wrote 11, 12, etc., until I got to the bottom of the page. In the resistance column, he told me to skip two lines and double, skip two more and double again, etc., to give 2 Ohms for 13 gauge, 4 Ohms for 16 gauge, 8 Ohms for 19 gauge, etc. As the resistance goes up, the cross section goes down in the same proportion; thus the cross section for 13 gauge wire is 5000 circular mils, 16 gauge is 2500, and so forth.

After doing all of these and taking square roots of the area to get the diameters, I still had many gaps in the table. The next step was to go ten places on the size and increase the resistance by ten times to give us 10 Ohms per 1000 feet for 20 gauge wire. Now we can go up from 20 gauge to fill in for gauges 17, 14, 11, 8, etc. From 11 gauge we can go down 10 for 21 gauge, and so forth. In a very short time we get the complete table as shown in Table 1.

It is a pity this table is not quite exact, but it is close enough for any practical purpose. Mr. Steele also showed me how all of these numbers can be read from an ordinary slide rule. I will not go into this because slide rules are now ancient history.

Now I can't rightly say how this discussion of soft drawn copper wire will improve your life unless you join up with a few nuts like we were with entirely too much free time on our hands during the big blowout. An interesting coincidence to me is the fact that a wire three gauge numbers smaller than another can handle only half the power (it is half the size), and cutting the power in half is a change of 3 dB (decibels). In like manner, a change of six gauge numbers changes the power capacity by 6 dB, and so forth. ■

John Molnar WA3ETD
Executive Editor

WIN MONEY!

A new contest is starting in *73* this month that should interest authors and readers alike. Get ready for this one!

The author of the best article published each month will receive a check for $100 – in addition to our regular payment for the article. I can hear the questions now! How will the winning author be selected? Not by the staff, that's for sure . . . otherwise I would insure that my editorial would win each month!

The readership of *73* will select the winning article each month by voting on the reader service card in the back of the magazine. It's simple to cast your vote. On the bottom of the reader service card there will be a small box with the word "Winner" close by. Place the *page number* of the article's title page in the box. This eliminates all possibility of confusion, as some issues contain multiple articles by the same author. After voting, make sure to fill in the rest of the reader service card – advertisers appreciate the attention, and hopefully will continue to manufacture ham gear! Each month Dynamic Doreen (5'7", blond, blue eyes) will present me with the totals indicating the winner. In order to avoid confusion and late votes, each month's ballots will be accepted until the next issue of *73* is mailed. Start writing, authors! An extra C-note *will go* a long way toward a major piece of new gear.

An additional Christmas present will be presented to the best article of the year, voted upon in the December issue. The yearly top prize is a check for $500! Dream about that for awhile!

We have not forgotten those readers who vote each month. A periodic drawing will be held from all reader service cards containing a vote. If you need a nice piece of new gear for your shack, this might be the way to get it. Drawing dates will be announced well in advance.

10 GHz

Well, as promised, I finally completed an article on the Gunnplexer transceiver. If you have been following this column, you know that the Gunnplexer is a microwave front end that can be used in communications systems and Doppler radar devices. Working with microwaves is fun, and I think you will enjoy experimenting with Gunnplexers if you are into UHF tinkering. My article concerning the transceiver is in this issue, and it can be built for under $200 – depending on the state of your junk box. Cost is much lower if you use a broadcast FM radio as an i-f receiver.

Microwave Associates, the outfit that makes the Gunnplexer, has an interesting information package concerning experiments with amateur microwave equipment. Most of the serious experiments have taken place in Europe and England. Hopefully it won't be long before American hams get going on 10 GHz.

Don't fail to keep me posted of your experiments with the Gunnplexers. I will respond to any and all related correspondence. I'll see if I can talk Wayne into a prize for the best microwave article of the year – check here next month.

COMING EVENTS

Our OSCAR special issue is next month (November issue). You won't want to miss this one, as it is full of info about the new satellite. There are also plenty of new antenna projects – especially related to portable operation. I just built a 432 MHz circular polarized groundplane from one of the articles, and it works great. Details about the new Russian satellites will also be provided. Make sure your subscription is up to date!

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz.
OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz.
Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

Ultra Simple Diode Checker

-- for grab bag specials

Marion D. Kitchens K4GOK
7100 Mercury Ave.
Haymarket VA 22069

This simple diode checker is an up-to-date version of an idea that has been around for a number of years. It can be built in one or two evenings from the parts in most experimenters' junk boxes. The parts required are one resistor, two LEDs, and any 117 V ac transformer that will provide from 3 to 25 V ac. Discarded audio interstage transformers from old tube-type radios and TVs can be used. If all new parts are bought, the cost will be about $5.00, including the small aluminum box. The small cost can be recovered many times over by buying unmarked, untested, manufacturers' closeouts, diodes by the pound, etc., available from most discount mail-order houses (like Poly Paks). Bad diodes can cause disastrous results in some circuits and can be difficult to detect and locate in other circuits. It is a wise precaution to check them all before installation. This simple diode checker was conceived and built for just such purposes.

The Circuit

The simple schematic is shown in Fig. 1. The transformer provides a low ac voltage, through the current limiting resistor, to two LEDs connected back-to-back. The diode to be tested is connected in series with this combination and the return side of the transformer. The LEDs will respond to the four possible conditions of the diode under test. If the diode is open, no current flows and neither LED will light. If the diode is shorted, one half cycle of the ac voltage will light LED1 and the other half cycle will light LED2. Since each LED is lit 60 times per second, a shorted diode will cause both LEDs to appear lit continuously. If the diode is good, LED1 will light when the diode's anode is toward the return side of the transformer and LED2 will light when the diode's cathode is toward the transformer return side. By proper physical arrangement of the LEDs and diode, the LED near the diode's cathode will always light.

The resistor should be sized to limit the current through the LEDs to about 10 mA. Most LEDs will have a voltage drop of about 1.5 volts across them, and most signal-type diodes will have from 0.1 (germanium) to 0.5 (silicon) volts drop across them. The resistor value can then be found by subtracting

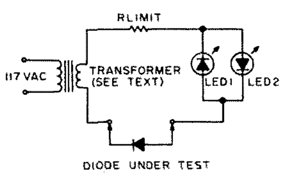

Fig. 1. Schematic.

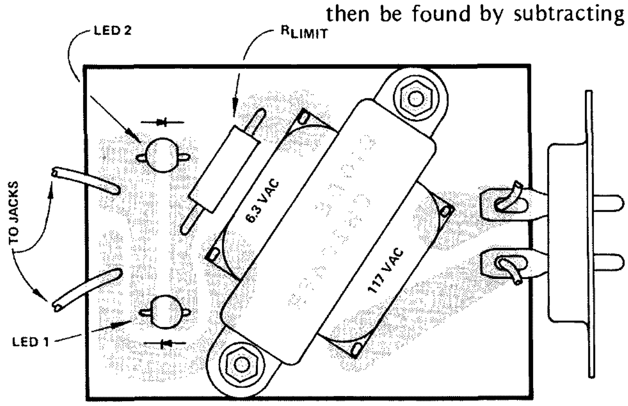

Fig. 2. Parts placement drawing.

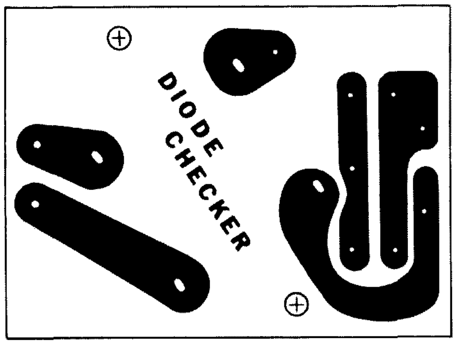

Fig. 3. PC board layout.

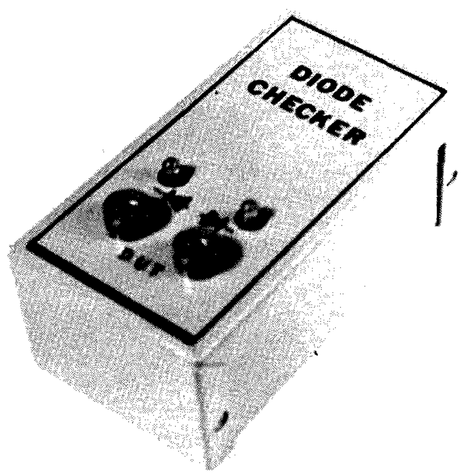
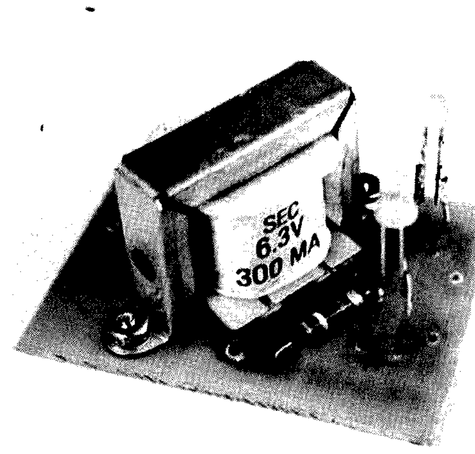


Finished, labeled checker.



Assembled circuit board.

these two voltages (say 1.5 and 0.5) from the transformer voltage and dividing by 10 mA:

$$R = \frac{V_{XFMR} - 1.5 - 0.5}{.010}$$

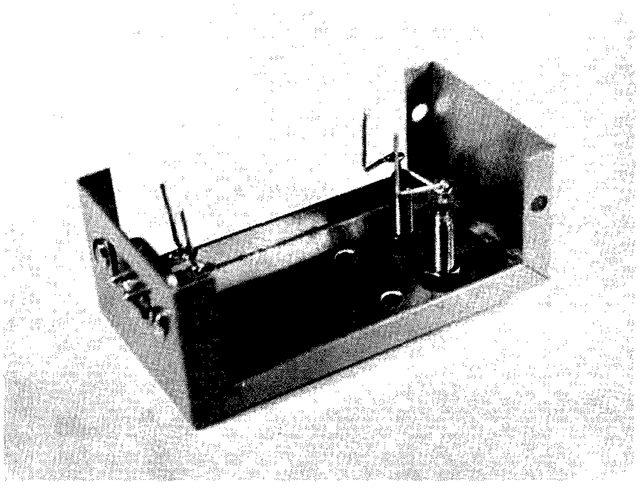
For a 6.3 V ac transformer, the resistor value is 430 Ohms. A 330 or 470 Ohm resistor will do. Its value is not critical.

Construction

The simple circuit lends itself well to point-to-point wiring, which is probably the quickest way to build the checker. If the builder prefers a neater appearance, the printed circuit board layout shown in Fig. 3 can be used. It is easy to duplicate with an etch-resist pen, or, if a professional look is desired, by photographic means. Fig. 2 shows the parts placement for the circuit board, and Fig. 4 shows the matching hole locations for mounting it in a 4 x 2-1/8 x 1-5/8 box. A Radio Shack 6.3 volt transformer, stock number 273-1384, was used for the circuit board layout and hole patterns. No on/off switch is used; the unit is simply plugged in for use. A TV cheater cord plug and socket are used so that the diode checker is easy to store without dangling ac cords everywhere.

Pin jacks, banana jacks, or five-way binding posts can be used for connecting to the diode to be tested. The binding posts allow for a variety of connections to diodes that cannot be brought directly to the checker. Adapters with a V-notch are used so that loose diodes can easily be dropped into place for testing. Fig. 5 shows two easy methods of making such adapters.

The holes should be cut in the box, and it should be painted and labeled to suit the builder's taste. The photographs show how I did it. The current limiting resistor and transformer should be mounted to the circuit board next. The ac plug and pin or banana jacks should then be mounted in the box, with short lengths of wire soldered to them as shown in the photographs. Next, insert the LEDs and bend their leads so that they will not fall



Box with jacks and ac plug ready for circuit board installation.

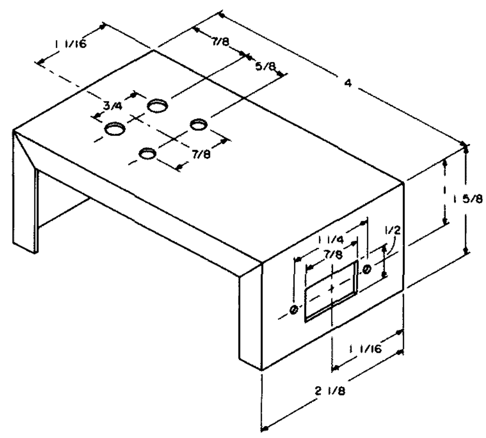


Fig. 4. Hole pattern for a 4 x 2-1/8 x 1-5/8 inch box. Cut holes to fit parts on hand. Holes are centered on centerline of box.

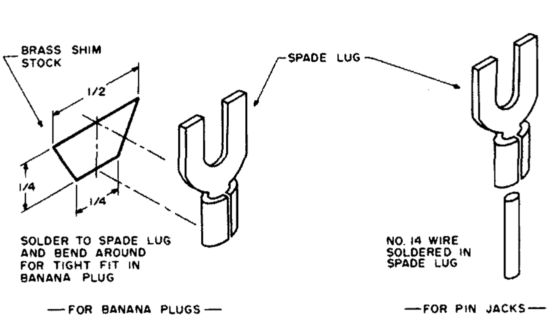

Fig. 5. Adapters.

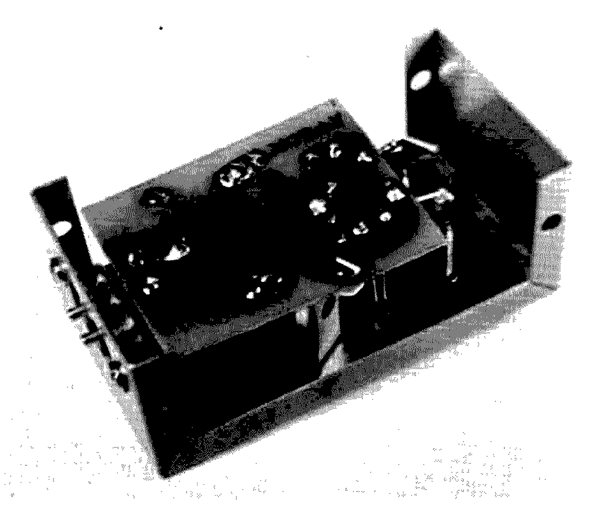
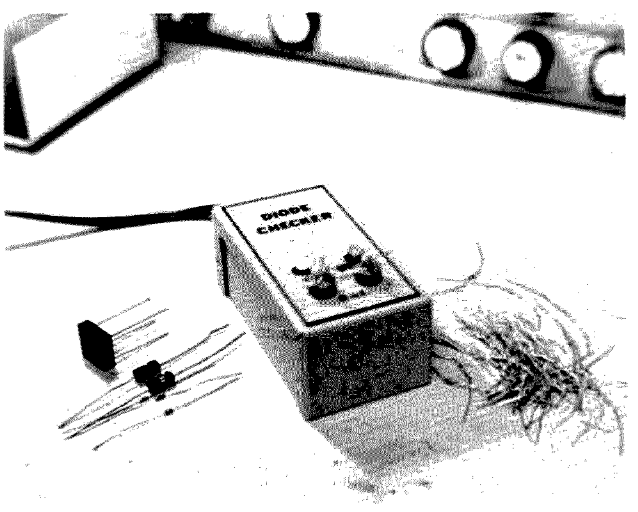


Box with PC board installed.



Finished diode checker in use.

out. Do not solder them yet. The LED leads must be long enough for the LEDs to protrude through the box, so the builder may have to add short lengths of wire. Now feed the four wires from the ac plug and the jacks through the proper holes in the circuit board, check for proper fit and clearance, and solder the four wires. Position the LEDs and solder them to the circuit board. Put insulation on the inside of the box bottom to prevent any possibility of shorts to the circuit board. Don't forget that it has 117 V ac on it! Make adapters to fit your jacks and you are ready to check out the unit.

Test the checker by applying power to the 117 V ac plug. Neither LED should light. Now put a short circuit across the jack terminals and both LEDs should light. A diode that is known to be good should now be connected across the jack terminals. The LED closest to the diode's cathode should light. Try it both ways to make sure the LEDs are oriented properly.

After building and using this simple diode checker, the owner will find a desire to also know if the diode under test is silicon or germanium. Since a germanium diode will develop about 0.1 volts across itself and a silicon diode about 0.5 volts, it seems that some very simple circuit might be devised that would light an LED if the diode under test were silicon. ■

Now you know where to turn first, Ervin! – J.M.

CQ SIX

Just a line to let you and your readers know that 6 meter AM is alive and well in Phoenix. Despite ugly rumors and speculation, our group is growing steadily and, with summer skip, widely. We operate two nets on 50.34 MHz – the Arizona Cactus Net on Tuesday at 0200 GMT and the Phoenix VHF Net on Wednesday at 0300 GMT. We have a calling frequency of 50.34 and it is monitored from 1400 GMT to 0500 GMT. We hope that some of your readers will look for us on 6 and relive some of those good old AM days.

Before you mention TVI, I'll say that I have had and continue to have some on 15 meters and on 80 meters too. While TVI is more likely to be a problem on 6 with channel 2, the 3rd harmonic of 21 MHz is right in the middle of channel 3. These problems can and are worked out every day by hams across the country. Nothing can surpass resolve.

For the new operator, this is the only way to get your own phone rig on the air, with a minimum of time, cost, and technical ability. While SSB is the best way to go for reliable communication, it is also the costliest and the more complex. Further, it makes appliance operators out of us, taking away our inventiveness, skill, and that thirst for knowledge. Just try to build as your first rig a home brew SSB rig. Unless you're an engineer, you might just as well pack it away. Six is cheap, it's dirty, and what is more to the point, if we don't use it, we are going to lose it.

This didn't start out to be a sermon, but I've said it and I'll stick by it.

Lawrence Day WB7EAX
Phoenix AZ

BAND PLAN

"Amplitude modulation and sideband can live together on 10 meters if there is sensible band planning," said Norm Lefcourt W6IRT, chairman of the recently created Southern California 10 Meter AM/SSB Band Planning Council. Lefcourt, noting the recent proliferation of conversion plans for CB rigs to 10 meters and the various proposals for channelization of the popular HF band, said unless everybody settles on a single band plan, no one will be able to talk to anyone. "Using crystal controlled transceivers," he continued, "makes the need for a single, widely accepted band mandatory – we have to be able to work each other on common frequencies."

"Some people want frequencies above 29.0 MHz, others are advocating AM frequencies in what has been sideband territory, some want monitoring frequencies at 28.8, and others have suggested using other monitoring freuqencies 5 to 500 kHz away," he said. "It is very confusing."

Council members tentatively approved a "comprehensive band plan" for 10 meters which begins in the sideband portion and ends in that part of the band which is now used by most of the AM operators. "That's very important," said Lefcourt, "because we don't want to exclude anyone." Most commercial CB rigs which have single sideband capability are also able to transmit and receive AM phone signals.

The Council's plan places channel 1 at 28.560, 1.595 MHz above the existing channel 1 on CB radios. The ratio remains constant on each new 10 meter channel, so that channel 23 is 1.595 MHz higher than CB channel 23; new channel 40 also is 1.595 MHz higher than CB channel 40, so the conversion plan will work just as well for 40-channel rigs as it does for 23-channel sets.

"This band plan puts our new channel 4 at 28.6, a commonly used SSB monitoring frequency, and our new channel 20 will fall at 28.8 MHz, the frequency generally used as an AM monitoring channel," said Lefcourt. "Incidentally, with this band plan, channel 40 falls at 29.0 MHz."

The council voted to make public its "tentative list" of 10 meter channels and indicated that a "final recommended list" would be forthcoming after other amateurs from around the country have had a chance to com-

Beat the PC Shortage

-- build (glue) your own!

Between Radio Shack, Lafayette, and Heathkit, there were 37 retail electronics stores in the area, and I couldn't get my hands on a blank PC board larger than 2 by 3 inches. As I required a board at least 6 by 8 inches, my choices in this preposterous situation weren't too attractive. I could abandon the project, wait for the local stores to restock, or try to get some by mail. None of these options appealed to me. I had already spent quite a number of hours laying out the artwork and wanted to get this project wrapped up.

As so often happens, I didn't have a blinding flash of inspiration and suddenly solve this problem. Instead, I waited until a local store finally got some in and then completed my project. But in the back of my mind, I felt a vague sense of frustration. Perhaps it was a sign of advancing paranoia, but I kept wondering when there would be another shortage.

One evening a few months later, I was half following something on television and thumbing through a copy of *The Radio Amateur's Handbook* when I spotted an item that looked interesting. In the section covering construction techniques, they suggested using epoxy to glue strips of copper to an unclad board. The idea was to glue the strips where you wanted conductors. By doing so you could get around having to etch a board.

Things clicked into place, and I immediately figured out the solution to any future shortages of circuit board. After all, if you could epoxy strips of copper to a board, it shouldn't be hard to epoxy an entire sheet of copper and make a real circuit board.

A couple of days later, I had the epoxy, some sheet copper, and a piece of phenolic perfboard. Following instructions, I cleaned the copper and phenolic board, mixed equal amounts of epoxy resin and hardener, and glued the copper to the piece of phenolic. I then placed them under a stack of books and left them overnight. Next morning I took a look at my circuit board and almost went into shock. When I gave the copper a little tug it peeled completely away from the board.

Feeling that I must have done something wrong, I tried again. First, I made sure that room temperature was in the range they recommended. Next, I used more weight to apply more pressure to the pieces while the epoxy was setting. Finally, I doubled the time for the epoxy to set from 12 to 24 hours. When that time had passed, I examined the board. As before, the copper just pulled completely away from the phenolic.

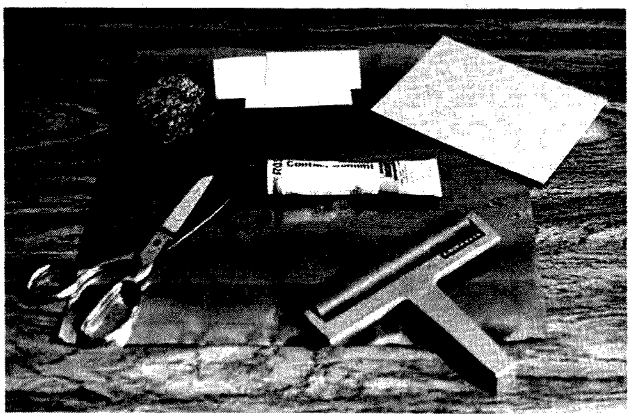

Fig. 1. Tools and materials needed are a pair of scissors, a steel wool soap pad, small pieces of cardboard cut from a filing card, contact cement, a sheet of copper and a phenolic board. The photographic roller is optional.

Fig. 2. Use the soap pad to thoroughly clean the surfaces of both the copper and the phenolic.

Fig. 3. Apply thin, even coats of contact cement to the copper and phenolic using small pieces of cardboard cut from a filing card.

I must admit that I felt foolish. Years of advertising had convinced me that one drop of epoxy will hold anything to any other thing. If there was an outside chance of some combination of materials being beyond the power of epoxy, I seemed to have found it. While many discoveries make you rich and famous, I felt that this wasn't one of them.

At this point I used a little logic and deduced that commercially prepared circuit boards don't grow out of the ground, so there had to be some glue that would work. If I tested every glue I could find, it was probable that one of them would do the job. Dim memories of the thousands of experiments Thomas Edison performed when he was searching for a filament that would work in the electric light gave me inspiration. The saga of San Juan Hill lent me courage, and my local hardware store made a fortune selling me a lot of glue.

I don't intend to bore you with the details of every experiment I tried, but let me tell you about one that almost worked. In their advertisements, they refer to it as "Amazing," "Incredible," "Stronger Than Steel," and "A Space-Age Miracle," Well, it was. And fast. If I applied a drop of it to a piece of copper about an inch square and stuck the copper to a phenolic board, within a couple of seconds it was bonded tight. And once they had bonded, there was no way short of an atomic blast to separate them.

The problem was that when I tried to spread that stuff over a piece of copper larger than one square inch, it started hardening before I could finish spreading it. Once that happened, it wouldn't stick to anything. So if you feel like making some tiny circuit boards, give it a try.

The Solution

Persistence on my part was finally rewarded. When I tried contact cement, everything worked so well that I almost forgot my earlier disappointments. Not only did it do a fine job of bonding copper to the board, but it also withstood prolonged soldering operations from a 140 Watt gun after I had etched out a circuit. And since so many people use contact cement, it's made by several companies, is priced fairly low, and comes in containers ranging from small tubes to five gallon buckets.

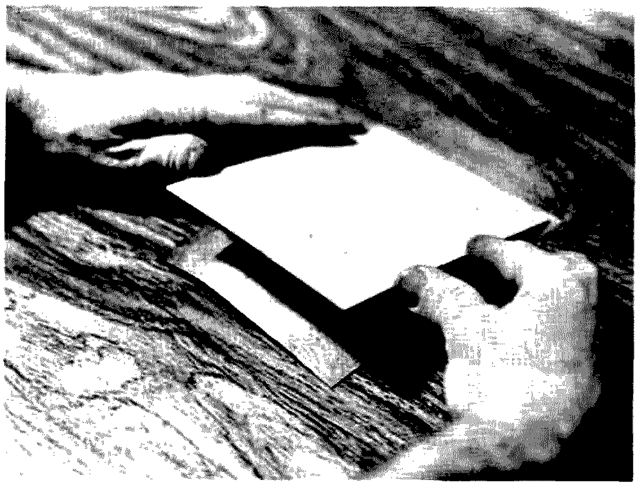

Fig. 4. After allowing the contact cement about ten minutes to dry, carefully align the coated surfaces and press them together.

If you are interested in rolling your own PC boards, let me quickly run through the procedure I use. I think you'll agree it's so simple that you won't have any hesitation about trying it.

The first step is to gather up all of the materials required. These include contact cement, phenolic board, and a sheet of copper. Once you've made these purchases, you will want to round up the simple tools required. These tools are a pair of sharp scissors, a steel wool soap pad, some pieces of thin cardboard cut from a filing card and, if you have one, a photographic roller.

The copper sheets can be found in hobby shops. They are available in several thicknesses, and I strongly recommend that you get the thinnest you can find in order to keep down the time required for etching. You should be able to find contact cement at any hardware store or in the hardware section of most discount stores. Phenolic

Fig. 5. I used a photographic roller to apply even, heavy pressure to the joined pieces, but you can use the palms of your hands.

boards are available at Radio Shack or similar stores. If you want to give it a try, sheets of formica should work very well in place of phenolic. Formica is available in many colors and patterns which could go a long way toward dressing up the average project. And, based on costs per square inch, formica is much cheaper than phenolic.

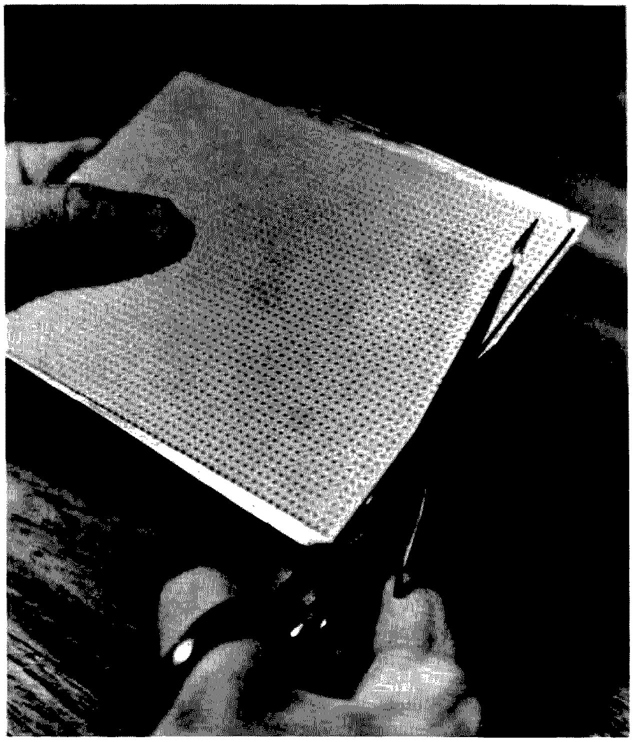

Fig. 6. As your final step, trim away any excess copper with a pair of scissors.

Once you have these materials and tools, begin by using the steel wool soap pad to thoroughly clean both the copper and phenolic on the sides you are going to apply the glue. The copper sheets I bought were coated with a transparent film to keep air from contacting the copper. Since I felt this film might interfere with the bonding process, I removed it with the soap pad. If your copper lacks this coating it will probably be heavily oxidized, which means a good scrubbing will be beneficial.

The copper takes on a highly polished appearance when it is properly cleaned. Once the entire sheet takes on a good shine, rinse it thoroughly and allow it to dry. Giving the phenolic a scrubbing helps to roughen its surface slightly and gets rid of any dirt or oil that might be present. Again, rinse carefully and allow to dry.

After the copper and phenolic are clean and dry, place them on some newspaper and apply the contact cement. Using small pieces of cardboard cut from a filing card, spread the contact cement evenly over the entire surfaces of both the phenolic and the copper. Strive for thin coats and work fairly rapidly.

When both surfaces are properly coated, set them aside and allow them to dry for about ten minutes. Then carefully align the two coated surfaces and join them together. Using either your hands or a roller, apply fairly heavy pressure to the pieces for a few seconds in order to insure good contact between them. Finally, trim away any excess copper with a pair of scissors. ■

"We want to hear from other hams," said Phil Kogel W6MRQ, "because if they keep sending their thoughts to magazines as letters to the editor, there'll be hundreds of band plans but no real band planning." Kogel asked anyone with comments to send them to him, W6MRQ, 1245 North Laurel Ave., Number 9, West Hollywood CA 90046. "Please send a self-addressed, stamped envelope if you want a reply," he said. "We don't have the funds to mail copies of our final frequency chart to everyone."

John McAulay WA6QPL, a QRP sideband operator, said the council will not advocate exclusive use of any frequency by either AM or SSB. "Normally, SSB is in the low end, AM a couple of hundred kHz higher," he said. "But there is no reason why one operator on SSB shouldn't enter a QSO with another on AM. As long as they can understand each other — that's all that counts."

John English WB6QKF, council vice-chairman, also pointed out that the council is giving some thought to planning a portion of the CW band for Novices. "Right now," he said, "we're thinking about 8 CW channels (28.105, 28.115, 28.125, 28.145, 28.155, 28.165, 28.175, and 28.195) which would put low cost HF gear in the hands of Novice operators who can't afford to spend a lot of money on equipment."

This letter reflects the opinion of the Southern California 10 Meter AM/SSB QRP Band Planning Council. What a title! — J.M.

In your June, 1977, issue, a band plan for CB/10m conversion suggests the use of the OSCAR downlink frequencies. Please! Please! — Don't.

Since you need 230 kHz bandspace, I suggest you add 2.0 MHz to get 28.965-29.255. This band plan will be easy to relate to CB channels using 10 meter spectrum that is less used than others.

Don't forget the 10m Novice (28.1-28.2), the 10m DXer (28.5-28.8), and most of all, OSCAR (29.4-29.55), when preparing a potentially heavily used band plan on 10 meters.

Even so — I would strongly recommend SSB or FM in lieu of AM. If this plan becomes successful, AM will lose in the end anyway.

My conversion of a CB set would consist of:

1. Move frequencies to slot of interest
   a. AM (28.965-29.255) (why hassle the SSB and OSCAR boys?)
   b. FM (28.965-29.255)
   c. SSB (28.665-28.955) (think of the mobile DX work when the band is open)
   d. CW (28.465-29.755)
2. Disable AM modulator
3. Install varactor FM modulator
4. Install FM discriminator (careful use of AM detector will work)

Yes — convert those rigs, but plan the *new use* around *existing use* to add to the hobby.

Bob Winchester W8LSS
Midland MI

CB to 10 meters is great. Past three issues bring this interesting phase of ham radio to the front.

Keep pounding on this, Wayne; this could be the start of something big . . . big as 2m FM repeaters. We hams need to do something with the 10 meter band or it will be given to the CBers.

I have my set all ready for its new crystals and am now putting up a modified CB beam to get active on 10m AM.

Wilbur T. Golson W5CD/4
Panama City Beach FL

Now is the time to get a firm channelized band plan for 10 meters. We have seen two or three frequency plans, and if people use different sets

Identify That Transformer

-- tips for using boat anchors

The experimenter often relies on junk box parts and surplus electronic parts. Many power transformers are marked clearly, but even unmarked transformers are perfectly usable after they have been tested and rated.

Even the completely unmarked transformer will usually offer clues to its design. For example, the ac input leads (primary winding) are usually color-coded black. Other windings probably will be yellow or green. If the transformer has a large number of secondary windings, it may have a high voltage winding color-coded red, and other leads will be yellow, green and brown. If any winding has a center tap, this wire usually is striped in the same color as the winding. For example, a yellow coded winding might have a yellow center tap with a blue stripe.

Fig. 1 shows a transformer as a "Black Box" – a unit with unknown characteristics which must be deduced. Begin by verifying that leads of the same color connect to the same winding and not to another winding. Then, measure the dc resistance of each winding.

At this point, the black box of Fig. 1 has been indentified to the point shown in Fig. 2. The next step is to apply line voltage to the black winding through a 1/8 Ampere slow blow fuse and measure the voltage on the other winding. In this particular example, the ac scale on a VOM showed a no-load output from the secondary winding equal to 12.5 volts. This was measured with 122 volts ac in (line voltage is high in Texas).

The next step is to load the transformer enough to determine a safe power rating. Since the transformer will be used for a dc supply, make a rectifier-filter network as shown in Fig. 3. The capacitor value is not critical so long as the dc ripple under load is no more than 5% (a typical value might be 2000 uF). Remember that the voltage rating for the capacitor must be greater than 1.4 times the no-load transformer output voltage. For the transformer under discussion: 1.4 x 12.6 V dc is the minimum allowable voltage rating.

Determine the current rating of the transformer by applying a dc load to the rectifier-filter network until the ac voltage of the output winding drops by 10%. This dc current rating then can be multiplied by the dc voltage to get a power rating. For the transformer illustrated, a 250 milliamp dc load reduced the 12.5 volt ac (open circuit) to 11.3 volts. With that load, the dc out was .25 A x 11.6 volts = 2.9 Watts. As a final check, weigh the transformer; allow about 1 ounce per Watt of power.

The dc load for the transformer can be power resistors, but the circuit of Fig. 4 is easy to build and is easily variable over a wide range. (Q3 is a power transistor and must be mounted on a heat sink.) Choose R1 with the formula R1 = .6/1 minimum; for 50 mA minimum load, R1 = .6/.05 = 12 Ohms. The upper current limit will be set by the value of R1 and the output voltage of the supply. For a 12 volt supply, the maximum current would be about 1 Ampere.

The final check for any transformer is to operate it with rated load for several hours. If there is any problem with the transformer (shorted turns, etc.) or if the load is too high, the transformer will get hot. In general, transformers run a little warm, but the transformer should not be too hot to touch comfortably. ■

Subaudible Tone Encoder

-- access those closed machines

With the ever increasing two meter activity, many repeater owners have chosen to incorporate PL, CG, or QC as a means of accessing their machines. A subaudible tone is required to access and maintain your signal through the repeater. At the repeater site, a subaudible tone decoder is interfaced with the receiver. When a transmitted signal opens up the receiver, a subaudible tone must be present on the incoming audio, so the decoder will close a relay and permit the transmitter to key up and repeat the signal. All individual users must provide a means of generating a specific subaudible tone on their transmitted signal along with their voice audio. There are two main requirements, tone frequency and proper tone deviation of the carrier frequency. Tone frequency is determined by the particular repeater decoder frequency and the deviation level is usually around 350 to 500 Hz.

In areas where many different repeaters are available, it is necessary to have more than just one tone encoder. This article describes a six channel subaudible encoder that works very well. The circuit is laid out on a 1" x 3" PC board. Parts are fairly common to obtain and construction takes about an hour.

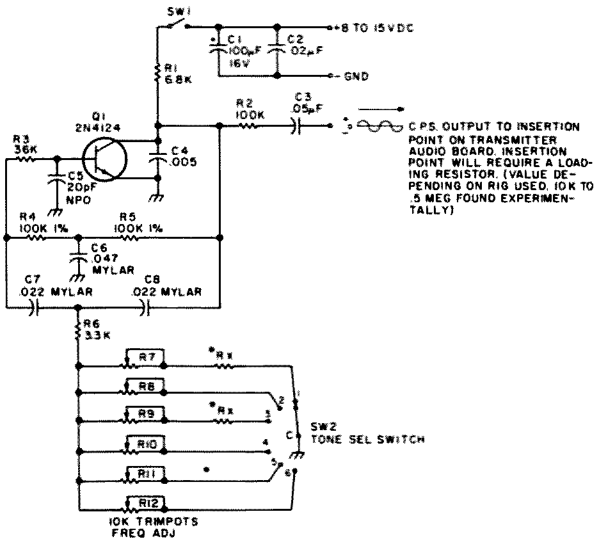

Fig. 1. Subaudible tone encoder.

The basic circuit is a twin T oscillator designed to operate in the subaudible tone range (93 to 170 Hz) for amateur use. It is versatile because the tones are adjustable with 20 turn trimpots. The theory of operation can best be described by saying R4 and R5 and C6 form a low pass type network. C7 and C8 and R6 and R7 form a high pass. As the phase shifts are opposite, there is only one frequency at which the total phase shift from the collector to base is 180 degrees, and oscillation will occur at this frequency. Optimum operation results when C6 is approximately twice the capacitance of C7 and C8, and R6 and R7 have a resistance about 0.1 that of R4 or R5. (R4 = R5) and (C7 = C8). Output is taken off from the collector of Q1 via R2 and C3.

By decreasing R6 and R7, the output tone will go higher. If R6 and R7 are increased, the output frequency will lower. This allows adjustment of oscillator to a precise output frequency, anywhere in the subaudible range.

Frequency is set by feeding the output into a counter. This will get you into the ball park. Adjustment of R7 will bring the encoder to a precise frequency desired. Next, connect the encoder's output through an insertion resistor to an audio injection point on the transmitter audio board. The output of this encoder is quite high (1 volt). An insertion resistor will be required. Values range from 10k to 0.5 megs and is found experimentally and varies between rigs. Choose a value to obtain about 500 Hz of tone deviation. Key up transmitter; "fine" tweak R7 for reliable results with the repeater. Set up each trimpot

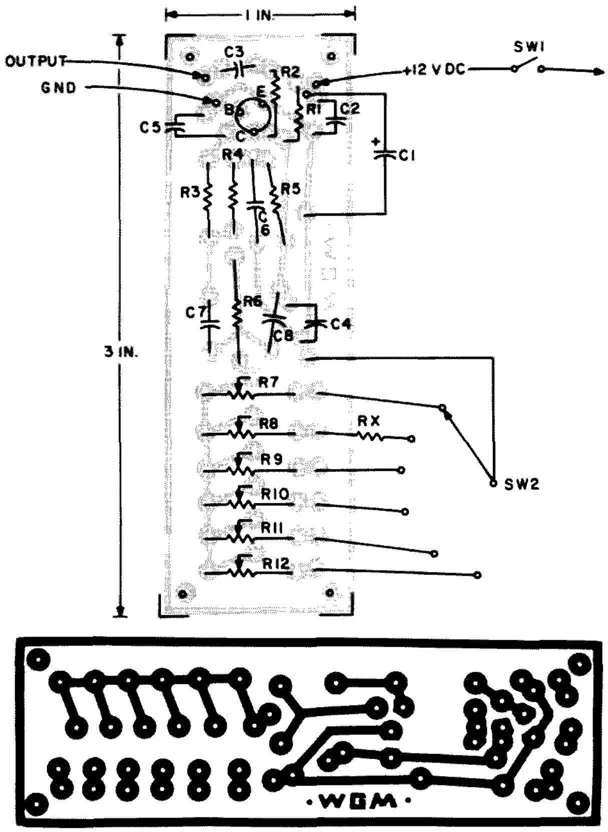

Fig. 2. PC board and component layout.

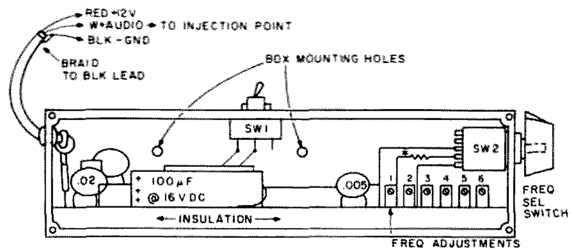

Fig. 3. Suggested layout of board in enclosure.

for a different required tone.

The ability to have six individual tones will probably be a great asset in the near future of repeater users. More and more repeaters are going the subaudible route, because of the FCC monitoring requirement, and the many problems with co-repeater interference. This unit is easy and reasonable to build for around $18. It has been in use for a couple of years with excellent reliability. ■

of frequencies, we will have chaos. Rigs will have to be modified to travel from one area to another.

We personally approve of the plan by WA4MFT. We are ready to buy rigs and modify them as soon as a firm set of frequencies can be established.

Ed Johanson K7TEO
Sandy UT
John Dorociak WB7PQI
Layton UT

I am writing about your articles on CB conversions to 10 meters. The Mokan chapter of 10-X International has sponsored our group to increase activity on 10. The whole project was started just before your first article on the subject, and after we had converted several rigs, we found out that you had proposed a different frequency scheme than we had (Murphy's law). We favor a standard scheme that everyone can follow so that when the band opens, we do not cause interference to everyone on the air.

We favor the use of 28.800 MHz because this is the nationwide AM calling frequency and there are several nets, including the 10-X net, on this frequency. We also favor keeping the channels low in frequency. The lower channels can in effect be DX channels, and the upper ones can be for rag chewing. There is also the possibility that many people will use phase locked loop rigs which can be modified to create 70 or more channels. The frequency scheme we propose would allow a PLL rig to have 60 channels and still not interfere with OSCAR satellite operations. Well, here it is — *another frequency scheme*:

Channel	Freq.

* Universal calling frequency

Jay Sprenkle WBØOUG
Kansas City MO

What's the matter with you people at *73*? I decided to convert a junk CB I picked up into a 10 meter rig; however, after looking at all the 10 meter conversion articles, I was ready to give up. What good is a 10 meter AM rig if I am the only one with that set of frequencies? In all the letters and articles, I think there were nine different band plans, most claiming to be the best.

I would like all the people who have converted CBs and who use 10 meter AM often to drop me a note giving their band plan and most used frequencies. With this data, I will determine the most used plan covering the most popular frequencies and report it to *73*.

Darryl Holman WB9TCY
729 Ziegler Rd.
Madison WI 53714

Well, the CB to 10 plot thickens! The above letters are but a few of the pile received at 73 this month. We need a band plan. I would like to take Darryl up on his suggestion, and gather information from interested converts. If you like, send your comments to me and I'll combine them with information on hand — let's get this thing going. Of course, OSCAR frequencies must be considered in any plan, as several letters indicate. I can see that I'm going to have to fire up my old DX-60 on 10 AM and see what is going on . . . maybe I won't sell the goodie as previously planned! — J.M.

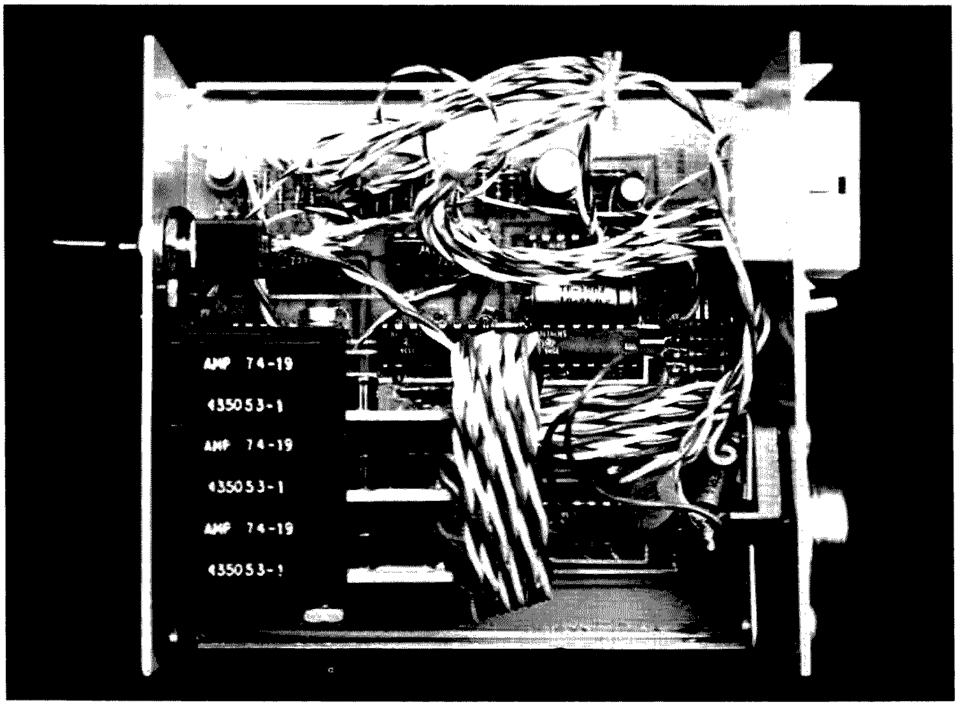
Build A ComCoder

-- versatility for the IC-22S

One of the most versatile two meter rigs on the market is the Icom 22S PLL synthesized transceiver. With the addition of a device we call the ComCoder, all of the channels that can be programmed into a 22S are available at the flick of three direct reading BCD thumbwheel switches.

Even though several commercial and homemade devices have been developed to increase the programming capacity of the 22S, we feel that the ComCoder is one of the most practical because it is relatively inexpensive, is easy to construct using off-the-shelf components, and is small in size. Moreover, the original 22 positions can still be used, duplex and simplex functions are performed automatically, and the unit can provide a means of remote operation. Perhaps the most significant feature is that any frequency in 15 kHz steps can be dialed in and read out directly on the switch numerals. No codes, charts, or mental calculations are needed. The frequency range covered by the ComCoder on our radios is from 145.340 to 148.215 MHz, in 15 kHz steps. The range below 146.00 MHz may vary from unit to unit. It should be noted that the range above 148.00 MHz is out of the band and should not be used.



Most owners of a 22S who have programmed the matrix board have probably noticed that the board has 23 positions, not just 22! The foresight of Icom in providing the 23rd position along with position 23 on the rotary channel selector switch (first dot past numeral 22) makes addition of the ComCoder or other systems a fairly simple task.

Inside the radio, only one very minor modification is required. Add two diodes, one resistor, a 24-pin accessory socket, and a few wires, and your 22S is ready to accept the ComCoder.

The following steps represent the minimum operations required to make the 22S ready to accept the ComCoder. (We say "minimum" because optional connections such as audio in and output required to remote the entire rig will vary according to the individual's desires.)

1. Remove the standard 9-pin accessory socket and replace it with a 24-pin accessory socket. Icom sells a 24-pin socket complete with bracket that will fit with no modifications to the rig. However, we used a molex #03-06-1241 female and #03-06-1241 male connector. The original bracket with a round hole for the 9-pin socket was carefully filed out into a rectangular shape to accept the 24-pin socket.
2. Disconnect the blue discriminator meter wire from the 9-pin socket, and reconnect it to pin 3 of the 24-pin socket. (See step 4.)
3. Disconnect the ground wire from the 9-pin socket and the board. Reconnect a new ground wire of approximately 20 AWG from the board to pin 4 of the 24-pin

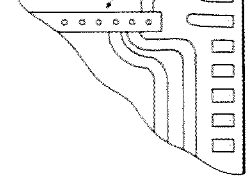


Fig. 1. Bottom of matrix board.

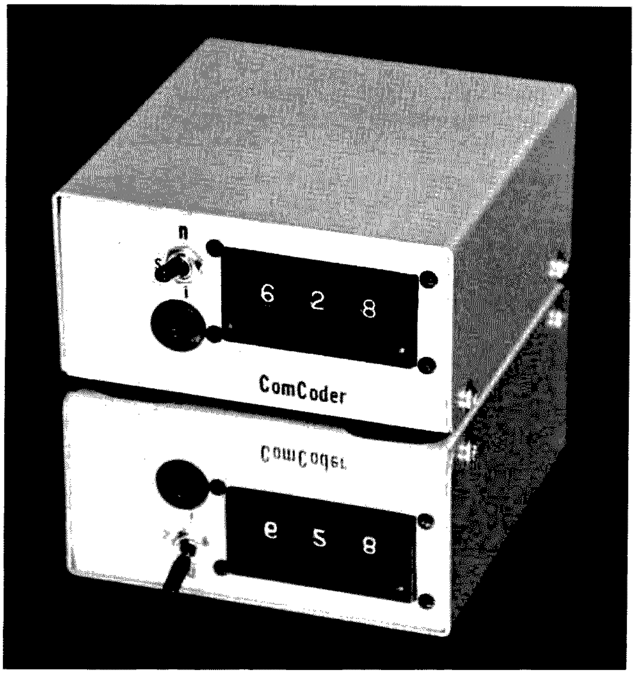

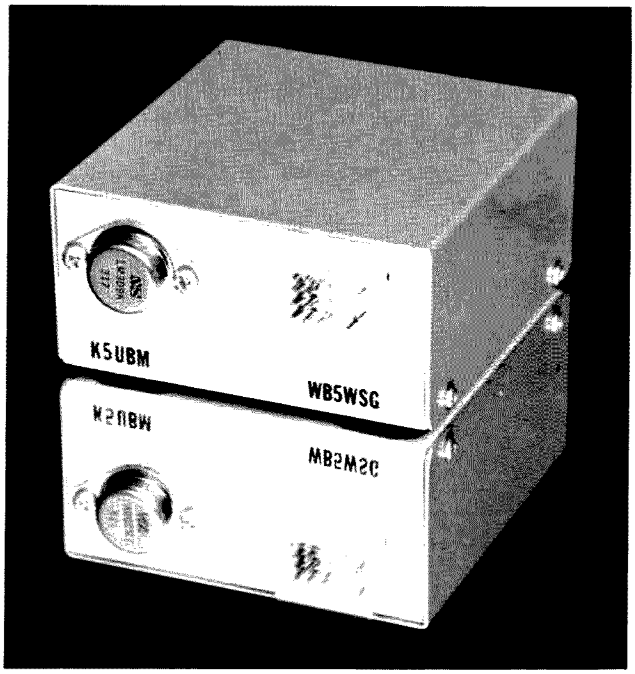

socket. (See step 4.)

4. Disconnect the .01 uF capacitor from the 9-pin socket and reconnect it between pin 3 and pin 4 of the 24-pin socket. This should be done at the same time as steps 2 and 3. We actually used a new capacitor, because it was easier than removing the one from the 9-pin socket.

5. On the bottom side of the matrix board, one strip of copper foil must be separated as shown in Fig. 1, and bridged with a diode. The cathode is placed toward the pin socket. A small triangularly shaped file works well for separating the copper. A diode of the same type used for programming the 22S (1N914) should be used. Cutting the copper at this point is the only real modification required.

6. On the top side of the matrix board, connect a diode to the second pin of the matrix board socket as shown in Fig. 2. This diode should be placed parallel with the end of the board, with the cathode connected to the pin. The other end should be passed through an existing hole in the corner of the board and connected to a wire. This method of installation stabilizes the diode and minimizes the possibility of the leads being broken during other operations. The wire from this diode is the DP line, and connects to pin 13 of the accessory socket. Use the same type of diode as was used in step 5.

7. Connect a 330 Ohm ¼ Watt resistor between the matrix board position 23 common bar, as shown in Fig. 3, and pin 16 of the accessory socket. The end of the resistor should be inserted through an existing hole in the corner of the PC board for stability. The wire from this resistor goes to pin 16 (+ 9 V) of the accessory socket.

8. Connect a wire from the position 23 pad on the bottom of the matrix board, as shown in Fig. 4, to position 23 of the rotary channel selector switch.

9. Install 8 wires from the matrix board channel 23 position locations D7, D6, D5, D4, D3, D2, D1, and D0, as shown in Fig. 3. The wires should connect to the 24-pin accessory socket, as shown in the accessory socket pin assignment (Fig. 5).

10. Connect an 18-20 AWG wire from the top connector (one closest to the squelch control) of the high-off-low switch to pin 2 of the 24-pin accessory socket. This is the 12 volt power wire.

11. Connect a wire from the push-to-talk wire to pin 5 of the accessory socket, as shown in Fig. 6. Connection is recommended at this point, to avoid disassembly of the front of the radio to get to the wire.

The wires connected to

the matrix board should be of sufficient length to allow manipulation of the board. After completing the above steps, the radio is ready to accept the ComCoder.

Before you start construction of the ComCoder, you probably will want to know how it works. Fig. 7 shows a block diagram of operation of the system.

In order to understand how the ComCoder works, the programming requirements of the 22S need to be identified. The 22S uses an eight bit binary code to control the phase locked loop (PLL). Normally this code is provided by the diodes in the transceiver and selected by the 23 position switch. A ten position binary coded decimal (BCD) thumbwheel switch produces a code that looks exactly like a binary until the number ten is to be encoded. A binary ten is 1010. A BCD ten is 0001,0000. Therefore, it would take two BCD switches to produce a ten and three to produce a three digit number such as 694.

The range of frequencies that the 22S can be coded for is from 00000000 (which corresponds to a frequency of 144.390 MHz) to 11111111 (which is a frequency of 148.215 MHz). Even though the 22S could be coded for 144.390 MHz, inherent characteristics of the 22S PLL will not let the unit lock up on frequencies in the upper 144 and lower 145 MHz range. Note that only three thumbwheel switches are required. The first two digits (1 and 4) and the 5 showing a 15 kHz are automatic. The 1 and 4 numerals could be painted beside the thumbwheel numerals if desired. The red LED lights to show a 15 kHz split frequency. For instance, when (14) 743 is dialed in, the red LED will light, thus indicating a frequency of 147.435 MHz.

The formula to convert a number such as (14) 6940 to the appropriate binary code is (6940-4390) ÷ 15 = 170. The 170 corresponds to the binary code as shown in the IC-22S owner's manual programming chart. This arithmetic formula required to convert a direct reading number (on the thumbwheels) is solved by the ComCoder. Detailed operation of the ComCoder is as follows:

1. The numbers on the three BCD switches are loaded into the three BCD counters. At the same time, a constant equal to -292(14390/15) is loaded into the binary counters.
2. The oscillator counts down the BCD counter toward zero, while every 15th pulse of the oscillator counts up the binary counter.
3. When the BCD counter reaches zero, 6940 pulses (assuming 14694 has been selected on the switches) have been issued and 462 pulses have been counted into the binary counter. The result of the -292 that was first loaded in and the 462 is 462 - 292 = 170. A pulse is issued to load the latch with this value.
4. The divide by 15 is reset and the process is restarted.

The components not mounted on the circuit board are as follows: capacitors C7 and C6, 5 volt regulator LM309, light emitting diode (15 kHz offset indicator), BCD thumbwheel switches, DPST center off duplex line switch, 1N2069 diode CR13, and the 24-pin plug. The 24-pin plug could be optional. The wiring could be made directly to the components and the circuit board. This is not desirable unless the unit is to operate in a permanent location. Any problems that show up after the unit is operational would probably be the result of a broken wire. Repair would be simplified by having the connecting cable capable of being plugged into the radio and the ComCoder. Also, the use of cables of different lengths for operations such as remote setup in your car and fixed in the house is more practical.

After you have scrounged or bought all of the parts, assembly is as follows:

1. Mount the components on the circuit board. Note that wiring is not critical and that alternate methods other than a printed circuit board could be used. However, in order to make the unit as small and neat as possible (as well as easy to assemble), a printed circuit board is recommended (as shown in the photograph of the inside of the ComCoder).
2. Prepare the housing box to receive the BCD switches, 5 volt regulator, LED, DPST switch, and 24-pin socket. Layout is not critical, but should generally follow that as shown in the photographs. Drill holes for the regulator pins and mounting screws. The pin holes should be approximately ¼ inch in diameter. Drill holes for LED snap mount and DPST switch. Drill starter holes for the BCD switches and 24-pin socket. A hand nibbler was used to complete the rectan-

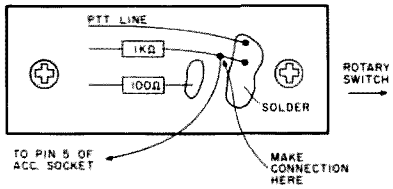

Fig. 6. PTT line connection procedure (located on the back side of the front panel).

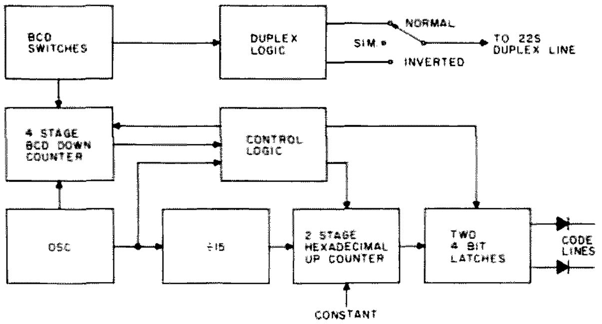

Fig. 7. Block diagram.

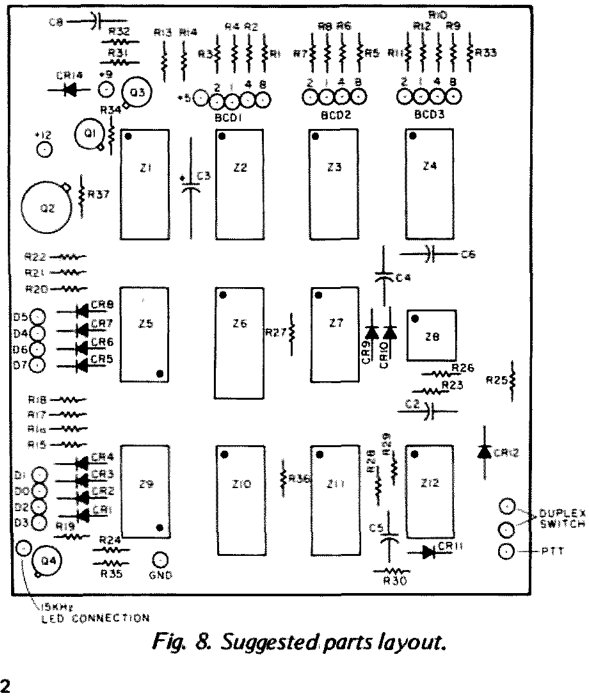

Fig. 8. Suggested parts layout.

gular holes for the BCD switches and 24-pin socket. If a nibbler is not available, the holes could be filled. Note that as shown in the photographs, the switches and LED are over to one side. This will allow the addition of a mike jack for remote operation.

3. Mount components listed in step 2 in their appropriate location. Do not install permanently at this time, because some of the wiring connections are simplified with components not mounted. We used a power transistor socket to mount the 5 volt regulator. This made the task of connecting C1, C7, and the wiring easier. Silicone grease should be used in mounting the regulator, to insure good heat conductivity. Also, if your box is painted, you should scrape the paint beneath the regulator.

4. Install wiring from the BCD switches to the circuit board. We mounted diode CR13 directly to the BCD switch connection points. The connection points are shown on the parts layout drawing (Fig. 8).

5. Install wiring from the PC board, regulator, and DPST switch to the 24-pin socket.

6. Connect the LED to the PC board. We used a snap mount type LED, but almost any type can be used.

7. Mount the PC board inside the housing. Make sure it is well insulated and makes no contact with the box or any other components (see test procedures).

8. Mount all other components permanently (see test procedures).

After completing the above steps, the unit should be ready to operate. However, before you connect the ComCoder to your radio, the following tests are recommended:

1. Measure the resistance from ground to +12 V dc and from ground to +5 V dc, to insure there is not a short.

2. Connect +12 V dc and ground to the unit. Measure +5 V dc. Connect PCB to 5 V dc. The 5 V dc should draw a current of approximately 500 mA.

3. If you have an oscilloscope, insure that the clock is running (555, pin 3).

4. Measure the collector of Q2. The voltage should be less than one volt.

5. Connect 5 V dc to R34, +9 V input to PCB. The collector of Q2 line should go to +12 V dc.

6. Select a 15 kHz frequency. The LED should come on.

7. Select 144.39 and measure each of the code lines. They should all be less than one volt.

8. Select 144.37. The code lines should all measure 12 volts.

9. Connect a 10k Ohm resistor from your meter probe to ground and measure each of the code lines. They should be less than 9.5 volts and greater than 7.5 volts.

10. Set duplex switch on normal. Select 146.34. Center of duplex switch should measure approximately 5 V dc.

11. Ground PTT line voltage should go to less than one volt.

12. Switch to invert. Voltage should go to 9 V dc. Unground PTT line voltage should be less than 1 volt.

13. Select a frequency of 146.52. The duplex line

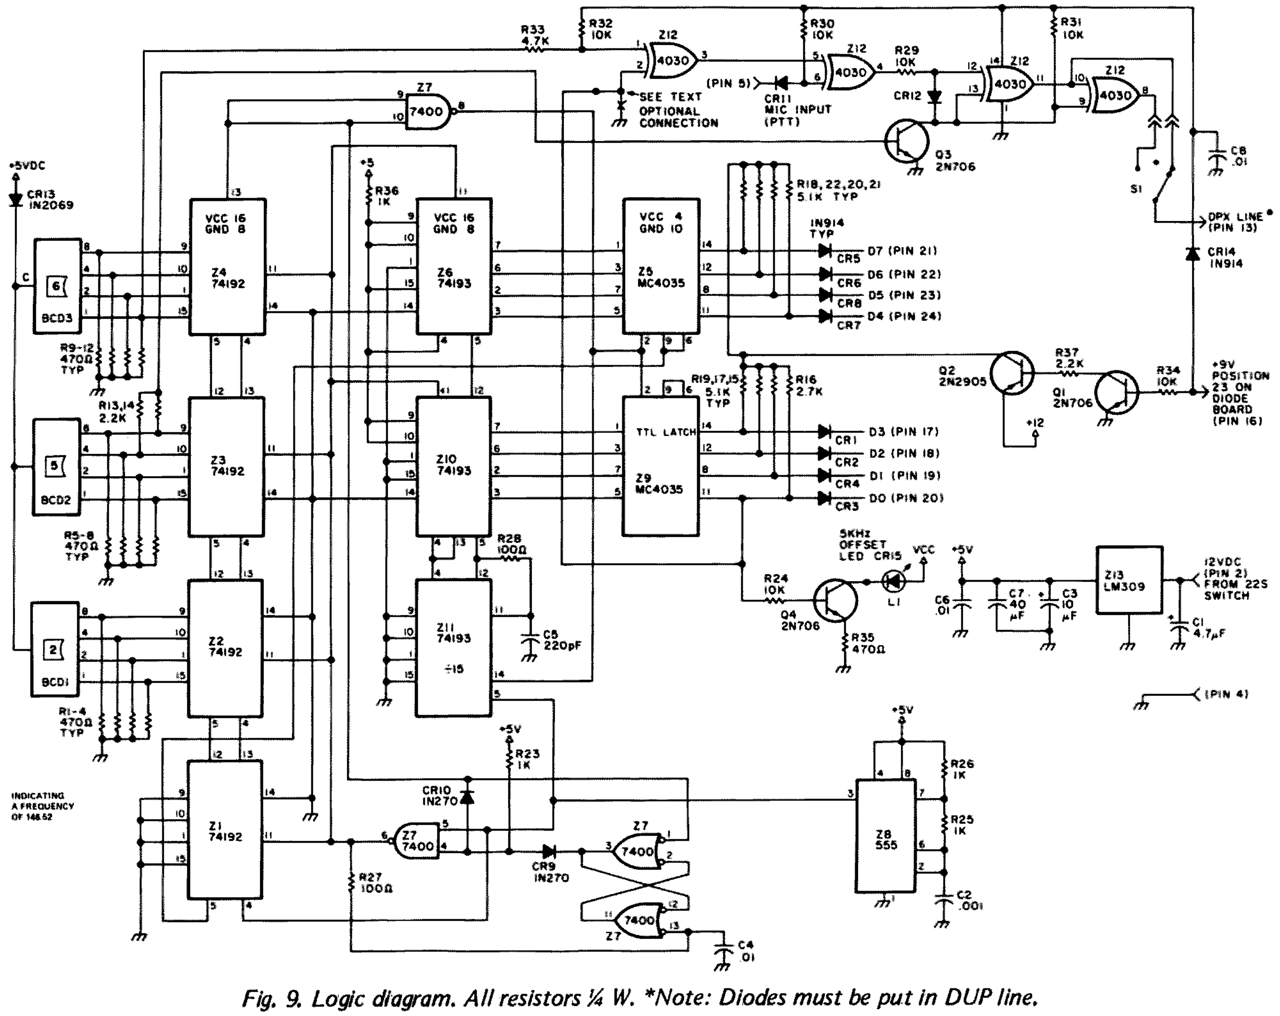

*Fig. 9. Logic diagram. All resistors ¼ W. *Note: Diodes must be put in DUP line.*

should measure less than one volt in all positions of the duplex switch, with the PTT grounded or ungrounded.

14. Select 147.00; voltage should be the opposite of step 10, -12. (Disconnect 5 V dc from R34.)

15. You are now ready to connect the ComCoder to your IC-22S. Caution! Remove power if there are any abnormal sounds or smells, or if lamps dim.

After everything has checked out, undertake the following operating procedures:

1. Connect the ComCoder to the radio via the 24-pin cable assembly.
2. Place the radio duplex switch in the simplex mode.
3. Place the ComCoder switch in the normal position.
4. Place the rotary switch on the radio in position 23 (the first dot past position 22).
5. Dial in the desired frequency on the ComCoder.
6. Turn the power switch on and start working!

Operation In Normal Position

Dialing in a frequency such as 146.280 with the ComCoder function switch in the normal position will cause the system to transmit on 146.280 MHz and receive on 146.880 MHz.

With the function switch still in the normal position, a frequency of 147.180 MHz will cause the system to transmit on 147.780 MHz and receive on 147.180 MHz.

With the function switch still in the normal position, a setting of 146.520 would cause the system to transmit on 146.520 and receive on 146.520.

What all of this means is the frequencies as follows are automatically simplexed: 145.400 to 145.995, 146.400 to 146.985, and 147.405 to 147.990. All others are automatically duplexed either up or down.

Operation In Simplex Position

Any frequency selected receives and transmits on that frequency.

Operation In Inverted Position

Normal duplex operations are reversed. For instance, dialing in 146.280 will cause the system to receive on 146.280 and transmit on 146.880. This mode of operation would be extremely useful for direct communication with other crystal controlled stations in the event of the repeater going down.

The optional connection shown on the schematic diagram at pin 2 of Z12 provides for automatic inversion of the 15 kHz split repeater inputs. This allows 15 kHz repeater operation with the function switch in the normal position.

Generally, all normal operations can be performed with the function switch in the normal position. The simplex and inverted positions are icing on the cake that let you do almost anything.

We hope you have as much fun building and using the ComCoder as we have. We would like to give credit to Gary Todd WB5LIF of Todd Photographics in Sulphur Springs, Texas, for his assistance and efforts in providing the photographs used in this article.

A kit including all electronic components and a double-sided printed circuit board with plated-through holes is available from Bullet Electronics, PO Box 19442, Dallas TX 75219, for $39.95. The kit contains all items required to build a ComCoder except the hardware, box, and switches. For those wanting to scrounge their own parts, a double-sided printed circuit board with plated-through holes is available for $10.50 from Bob Walker, 1608 East Tucker, Arlington TX 76010. On both of the above, add 5% for postage and handling. Texas residents should add 5% sales tax. ■

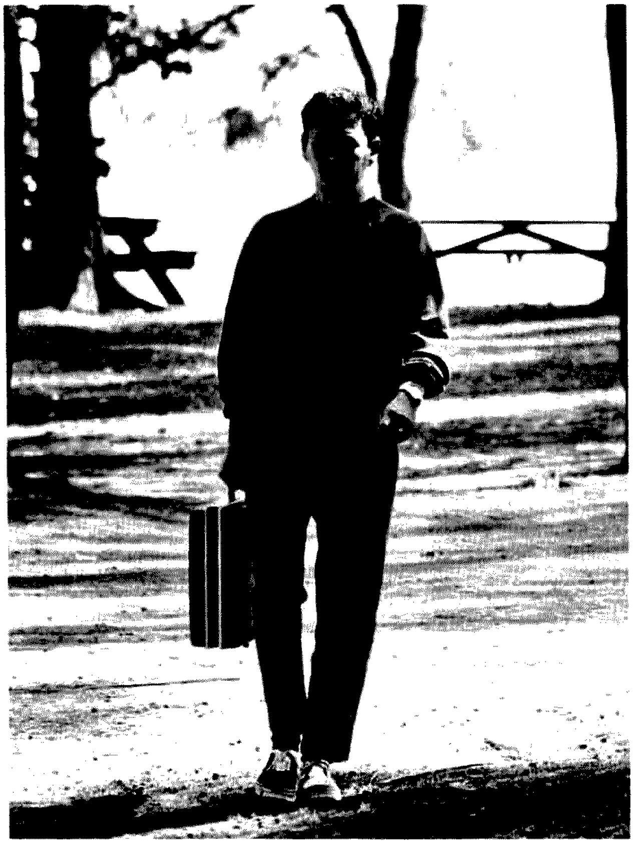
Attaché Case Portable

-- Bond would like it!

Albert H. Coya N4AL/WB4SCN
1710 SW 83rd Ct.
Miami FL 33155



James Bond and his counterspy gadgetry made the attache' case notorious a decade or so ago. The black vinyl rectangle became a symbol of the super-secret agent. Bond was able to produce weapons and communications devices from his case with the ease of a magician pulling rabbits from his velvet hat.

Usually, the attaché case contained a rapid fire 7 mm machine gun, smoke grenades, plastic explosives, a telescopic blowgun with a provision for darts impregnated in curare, a bottle of champagne and two glasses, and, of course, a two-way radio. With this radio (frequency unknown) and an invisible antenna, he always kept in touch with headquarters in London, even while traveling aboard a dromedary in the Gobi Desert.

Unfortunately, or fortunately, I don't have a license to kill, and my attaché case must be as legal as possible. So I will leave out the explosives, poisoned darts, etc., and will stick to the communications business. My attaché case portable may lack all those lethal weapons, but it contains an efficient and down-to-earth communications system.

As a staff photographer with the *Miami Herald*, I travel throughout the United States and abroad. On short trips I drive, but most of the time I fly. The long hours in a motel waiting for a newsbreak can be shortened if I do some hamming. But I needed to have a compact and portable operation.

I contemplated the need for two possible modes of communication – from a hotel or motel room and from a rented car. To attach the rig to the car, I built a telescopic center-loaded antenna with a gutter clip. To feed the 12 volts from the car battery, I used a long, stranded wire, twelve gauge, coded for polarity, and with heavy-duty battery clips on the end.

The motel operation is a lot simpler. Just be sure to get a room on the top floor. Open one of the back windows, and drop a long, covered wire down to ten to twelve feet above the ground level. Attach the end of the wire to the transmatch, tune the wire to the band of your choice, and you will be talking to the boys back home in no time at all.

In case you can't get a room at the top or it is difficult to drop a wire, the gutter antenna can be clipped to a pipe, the windowsill, etc., and, with the proper band tank coil, you'll go airborne.

For the attache'case operation I chose the Atlas 210X, because of its small size and light weight. I also have an ac power supply and a long wire tuner, compact enough to fit in my case, and coax, wire, pliers, screwdrivers, etc.

Lately I added to this a gel battery, capable of seven Ampere-hours at 12 volts. I use this battery on camping trips and picnics. I have my own private field days and talk to a lot of guys while the

steaks char in the barbecue pit.

On these trips I toss a long, covered wire over the trees and connect the end to the transmatch. On forty meters, stations from all over Florida start popping up. Everybody is interested in my portable operation. The fun starts when they pile up.

The seven Ampere-hour gel battery is compact enough to fit into the attaché case and strong enough for a full morning of rewarding QSOs.

One weekend I took the XYL and my attaché case to Cape Florida State Park, on the south tip of Key Biscayne across the bay from Miami. After biking and swimming, we took our things to a picnic table. While the XYL was preparing the food, I tossed a long wire over the pine trees and connected it to the transmatch. It is a very simple one that was advertised in *73* and sells for less than thirty dollars. Inside the little green box, you will find a toroid coil attached to a ten-position switch and a variable capacitor. Be careful when tuning this toy, because the rf jump can bite your fingers! A neon bulb tells you when the maximum output is obtained.

After installing the gel battery and mike, I started tuning the twenty meter band. It was buzzing like a beehive. At 12:20 pm Miami time, I got my first contact — Hank W3DX in Rockville, Maryland. Hank gave a good report, but he had a sked and had to QSY.

My next contact was a maritime mobile in the Pacific Ocean near Central America. He was calling a W7 station, so our QSO was short.

At 12:50 pm, TG9TG, a Guatemalan station manned by Glen, gave me a 5 by 6 report. Then I tried the forty meter band. Wayne W4JMU was near Jacksonville, Florida. The report was very good. In the low section of the forty meter band, a group of Cuban stations were talking to each other. I called CO2RS in Camaguey, and Ricardo answered my call. We got a nice report from the group, which included one ham working with an AM rig.

Then I switched to the 15 meter band. WA6SKI was on 21.350 MHz in Riverside near Los Angeles. I explained to him that I was having a private field day in Cape Florida. His signal was a solid S9, and he gave me a nice report.

Then the excitement started, when I asked Ray to phone patch my daughter, Susan, who lives in LA with her husband and my only granddaughter, Jenny. It was like a direct pipeline with the West Coast. My XYL had a great time talking with Susan. My daughter couldn't believe that we were sitting there on a picnic table facing the Gulf Stream. In the past, we had spent many hours together in the same spot, when she was in high school.

It was a tremendously satisfying and exciting experience, thanks to the kindness of Ray WA6SKI. I forgot to ask for his QTH to send him my QSL, but, Ray, if you are reading this story, I hope you have a smile and remember this interesting afternoon. ■

FILTER DESIGN MADE EASY

Active Network Design by Claude S. Lindquist is a new 749-page book which describes filter design and applications. It is an invaluable reference for engineers, technicians, and hobbyists who must understand signal processing and filtering, and who must specify, design, or adapt filters for their own uses. A.B. Williams of Coherent Communications Systems says, "It is the most impressive textbook on filters I have ever come across."

The book features standard design curves and tables, practical design examples, numerous problems with selected problem solutions, extensive references, original and unpublished research results, and complete cross-referenced index including applications.

The price is $21.95 prepaid ($23.27 for California orders) or add $1.50 postage and handling for 30 day billing. *Steward & Sons, P.O. Box 15282, Long Beach CA 90815.*

Corrections

In reference to "More Channels for the IC-22S," June, *73*, I would like to point out that the address of Bryant Electronics was in error on my part. Bryant Electronics is alive and well. To all those people who wrote for the boards, and the response was overwhelming, please write to me if you wish the board. To those who received theirs late due to having to have another batch made, accept my apologies. You should have them by now.

Build A Beeper Alarm

-- if staying in touch is important

Since the advent of my article, "The Ultimate Alarm II" (*73 Magazine*, June, 1973), there has been much interest in the feature which transmits a tone to a handie-talkie worn on the belt. This lets me know if the alarm is sounding while I am in a location where I can't hear the automobile horns. Moreover, people are impressed that I caught a thief in the act of tampering with my car even though he thought he wasn't setting anything off by climbing through a window. The vehicle described in the above article was broken into a total of 24 times by genuine thieves and, no doubt due to the article, "tested" numerous other times by enterprising individuals at hamfests. One such person jumped violently up and down on the bumper at an ARRL convention, thus destroying .94 talk-in facilities and making me immediately unpopular with several groups.

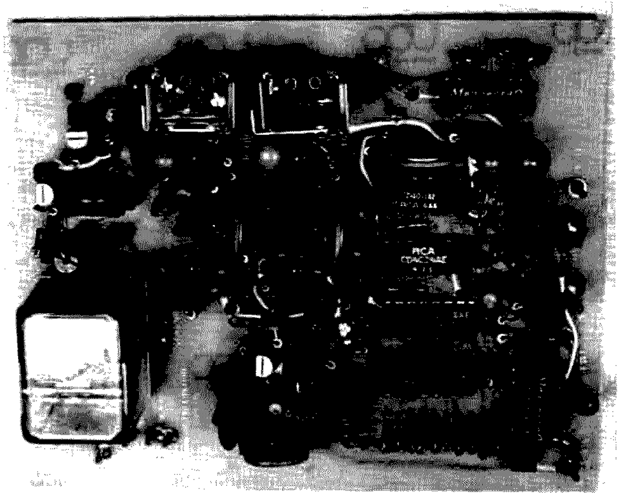
Another problem manifesting itself, and somewhat harder to rectify, was the fact that whenever I was in a theater, during the quietest and most suspenseful part of the picture, my handie-talkie invariably picked up other hams who would choose this time to vent their feelings on the traffic, the world situation, or other nonsense, at full volume and probably directly in front of said theater. This invariably did not sit well with my nearest neighbors or the management, and once, at a posh symphony concert, with the conductor himself. Usually I ended up by turning the receiver off, thus voiding the whole point of the thing.

The HT-220 handie-talkie was bulky, heavy, stretched my pockets on my jacket, and made me look like a plainclothes detective. Something had to be changed.

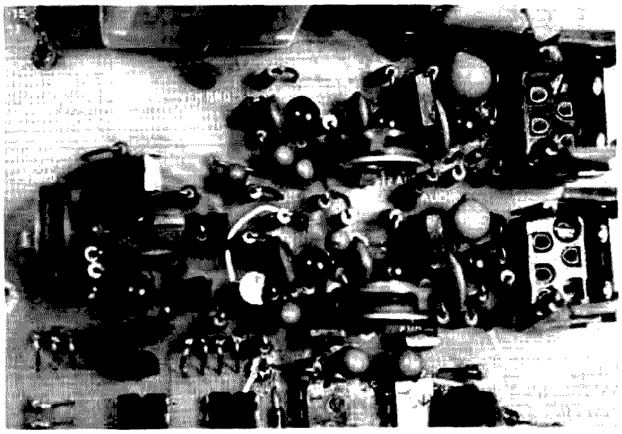
I then noted that at things like concerts or public meetings, no one got particularly upset when a bona fide physician's beeper went off. Here was an Important Person, clearly not a Xerox repairman, and armed with his beeper and a deprecating smile, he usually made his way to an exit with people nodding their approval and falling over one another to give him room.

It became obvious that there seemed to be a difference between physicians and hams.

Recently, feeling somewhat affluent, I purchased a new car and a Motorola Pageboy II (used) with no real idea of what I was going to do with either one. I was,



The completed PC board.



Another view of PC board. The two sockets are for the reeds. The two reed oscillators and the alert (ID) tone oscillator are the portion shown. Above these is the switching and sensor circuitry for the main alarm. Below are the ICs for the logic section.

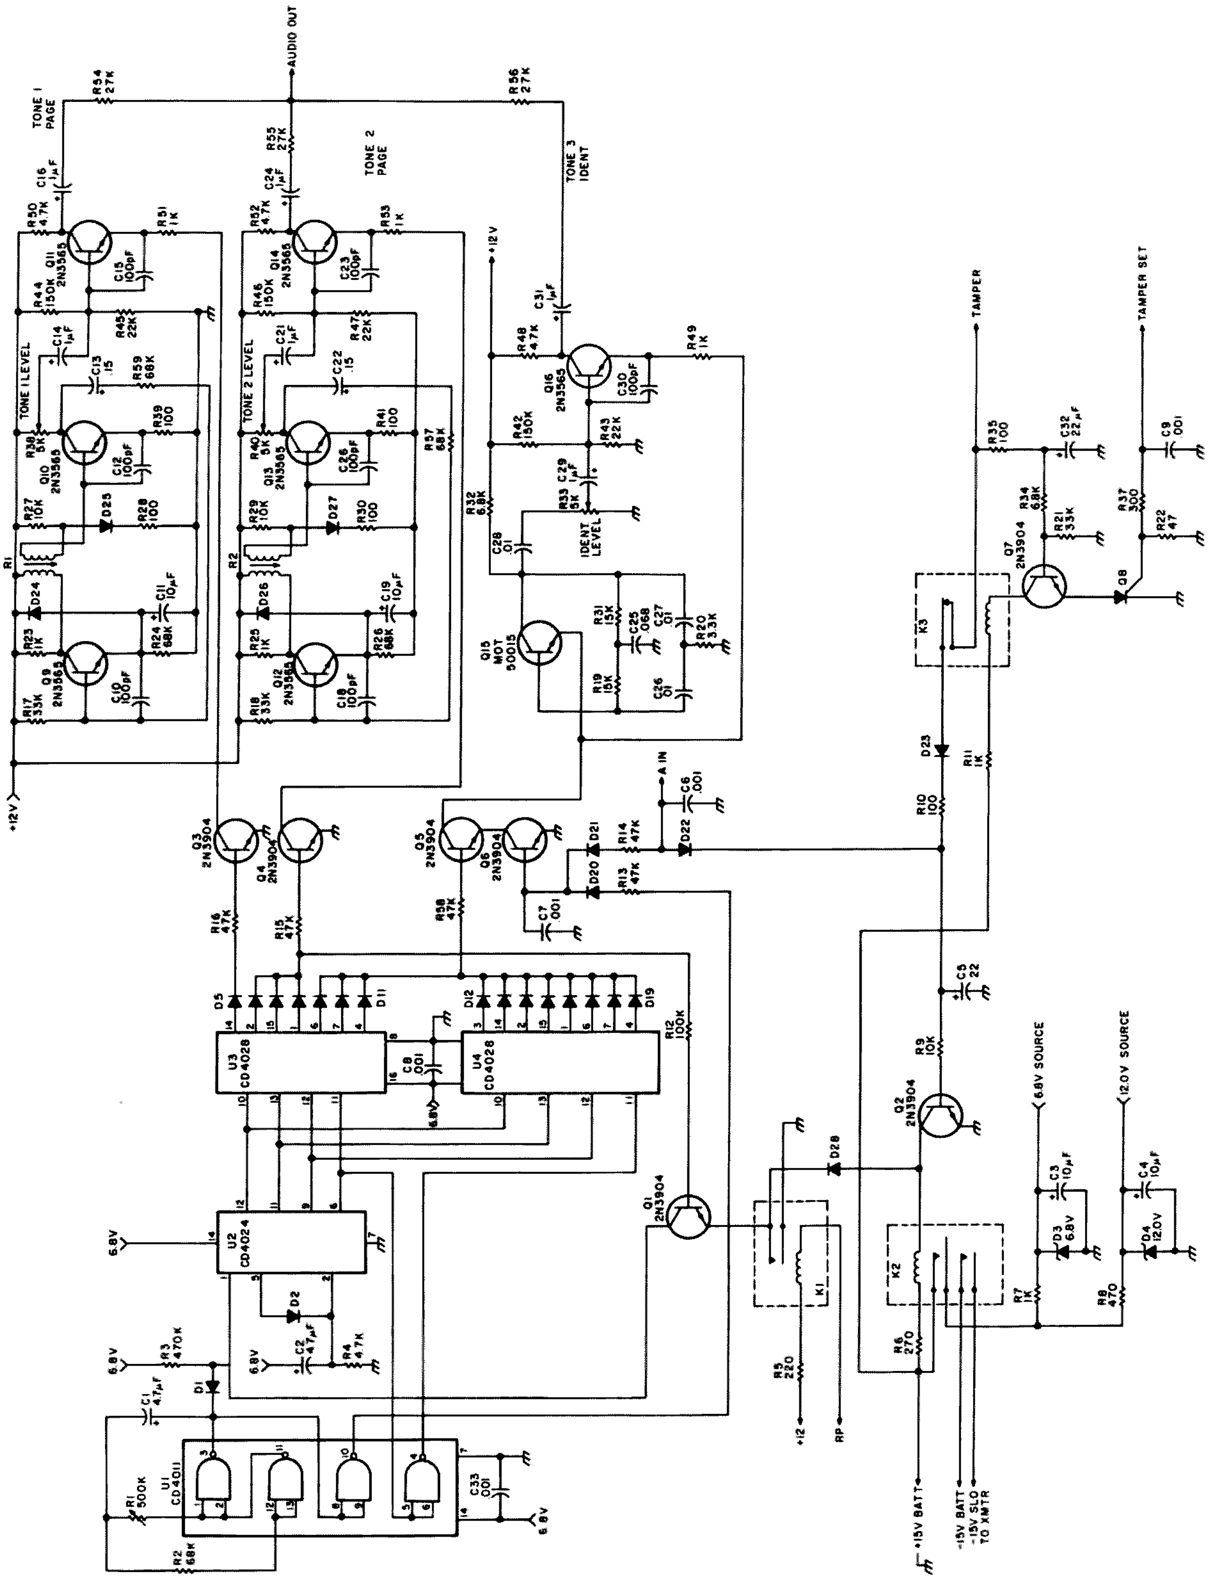


Fig. 1. Radio paging alarm circuit board schematic.

however, determined that anybody who scratched my new car while trying to break in would be dealt with severely. My old car had wear marks all around the various openings from all the attempts made on it. When I sold it, it was depreciated accordingly (should have been cleaned and burned). I, therefore, completely redesigned the alarm system from the collection of several dirty miniboxes full of electromechanical relays to a new integrated unit replete with transmitter, control board, test switches, and all the conceivable input/output combinations I would need.

The new unit provides the appropriate control to energize a 100 Watt elec-

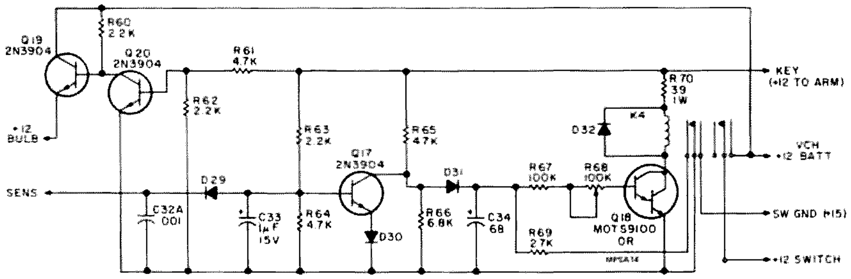

Fig. 2. Alarm switching and control for radio paging alarm.

tronic siren, the vehicle horns, and a 1 Watt transmitter. If tampering occurs, such as a car backing into it or someone attempting to climb inside, jack it up, steal an antenna, etc., a "silent" alarm is activated. This consists of motion sensors which activate a two-tone page and identification signal and a transmitter. The pager receiver is tuned to the same frequency and, with an off-on-off-on tone, indicates the car is probably being, or is about to be, modified in one way or another. Other sensors lie in wait and trigger another input if overt action is taken, such as the hood or doors being opened. The horns and siren then sound, the transmitter comes on, and a steady rather than pulsed tone is heard in the receiver.

The sensors are of many different types and are located throughout the entire car. Motion sensors in the front and rear detect motion of any sort and may be adjusted for various wind pressures and motion levels. Switches in the hood, doors, rear tailgate and crank up window (this is a Chevrolet carry-all) detect the opening of any of these. Vibration sensors on key parts of the auto are activated in case a window is hit or broken and an ultrasonic alarm sender-receiver unit is employed in the rear cargo area in certain instances. Finally, switch mats are used under portions of the carpeting. Should the main battery cable be cut from underneath (no easy feat) in an attempt to defeat the system, another battery used for the transmitter will sound the paging alarm anyway.

The circuit is laid out on a single PC board containing the counters, two-tone page oscillators, ID oscillator, and basic alarm switching circuit. Auxiliary circuits are also included for other functions to be described.

The transmitter is a 1 Watt transistorized unit from a GE Voice Commander II portable unit. I see these at hamfests for about $15.00 quite a bit. The transmitters may be easily removed, leaving only the receiver board audio circuits and case, which may then be sold to firemen, CBers, or monitor buffs for $30.00. The transmitters have a positive ground arrangement, so an auxiliary 15 volt battery, rechargeable and capable of 500 mAh or so, is used. This also drives the counter and tone circuitry to preserve integrity if the main vehicle battery lead is cut.

The antenna is mounted inside a rear window and consists of the solid inner lead of a piece of RG-59 stripped back about 19 inches or so for lowest swr (more on this). Mounted in this manner, it is almost invisible.

Before describing the circuit operation, it would be best to have an understanding of how a paging receiver works. There are basically two types: tone only, and tone-and-voice. In either case, a receiver is tuned to an operating frequency and will receive all signals transmitted over this frequency. If two sequential audio tones of the proper frequency are transmitted, the pager will emit a beeping tone which stays on for most of the duration of the second page tone. If a tone-and-voice pager is used, the speaker is then turned on and whatever audio is then transmitted will be heard.

My pager is a tone-and-voice Motorola Pageboy II with an "extra loud housing." The housing is a tuned cavity boosting the apparent audio output. Even with the larger dimensions, it is slightly smaller than a pack of cigarettes and fits nicely into a shirt pocket or on the belt.

There are several types available from several sources. A brand new Pageboy II from Motorola costs about $400.00. A used one may be procured for as low as $75.00 and a new charger for $20.00. Meshna advertised older low band units for $30.00. Other types are available from several sources, including hamfests or other surplus dealers. Ideally, you will want a tone-and-voice pager

utilizing a standard two-tone paging signal. Tone only units will suffice, but with my circuit, you won't be able to use the identification feature for break-in or tamper.

The alarm circuit is shown in Figs. 1 and 2. If the car is rocked or the motion sensors are otherwise put into motion, the tamper input relays a pulsed ground (remember we are using a positive 15 volt vehicle ground) to the base of Q2 through K3. C5 smooths this voltage and, with R9, provides a short delay to keep Q2 turned on. Relay K2 is energized and provides power to the transmitter and logic circuits. With regulated 6.8 volts and 12 volts now available, the CMOS clock provides a square wave to U2 at a rate determined by pot R1 and C1, the rate being adjustable by the pot.

At the same time, R4 and C2 provide an initial reset on U2 so that it starts counting from zero to insure the page tones get sent first, with the identification tone following.

U2 counts each clock pulse, providing a binary count to 16 to the decimal decoders U3 and U4, wired to provide 16 sequential logic ones at their outputs. These are used to turn on Q3, Q4, and Q5 in turn through diode coding. Q5 is clocked by Q4, which turns on and off with clock U1 if the tamper input is enabled. When Q3, Q4, and Q5 turn on, their collectors go low, thus enabling the tone oscillator outputs in turn. Q3 is on for one count and Q4 for 3 counts. These are the paging tone drivers, and, if the clock is made to run at an approximate 1 second rate, the required "on" time of the two tones will be automatically observed because of the diode coding. A pager requires the 1st tone be one second long and the 2nd tone three seconds. Q5 may be pulsed or steadily on, depending on whether the tamper or alarm inputs are enabled. The former is obtained by gating Q5 and Q6 with the clock so that a half second tone is generated. In the latter case, Q6 is turned on independently by the "alarm" input, providing a continuous path for the emitter of Q5. In this way, a continuous identification tone is generated after the fourth count.

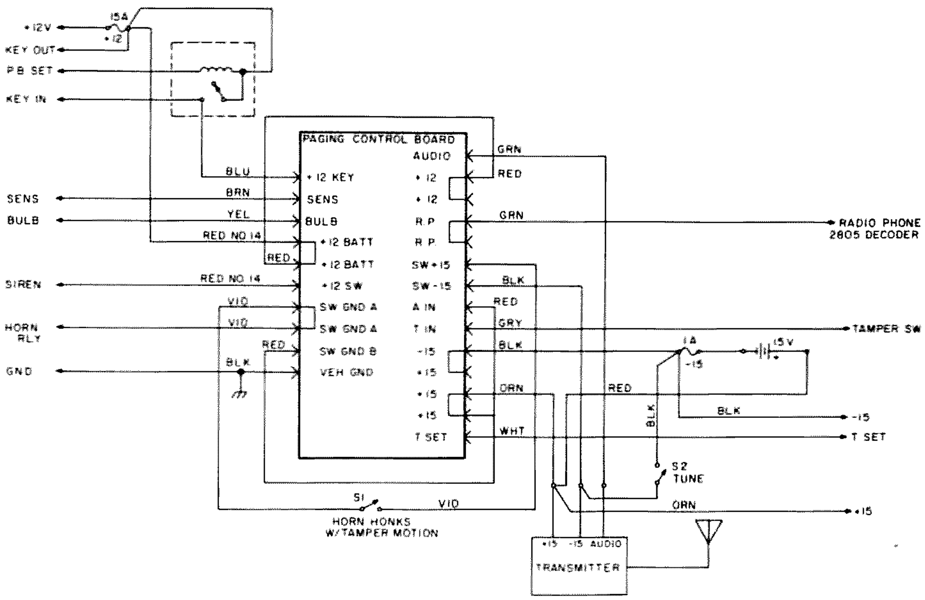

Fig. 3. Main wiring.

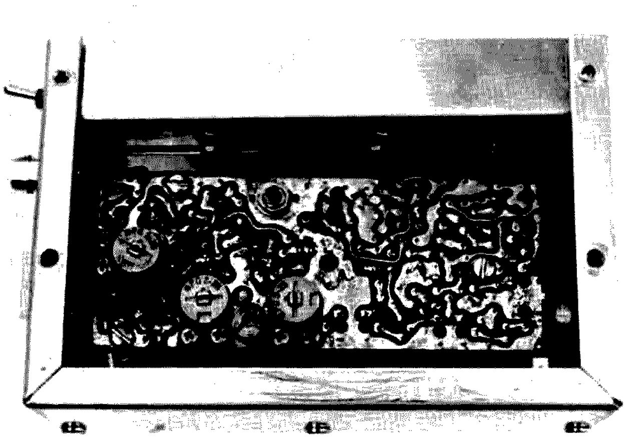
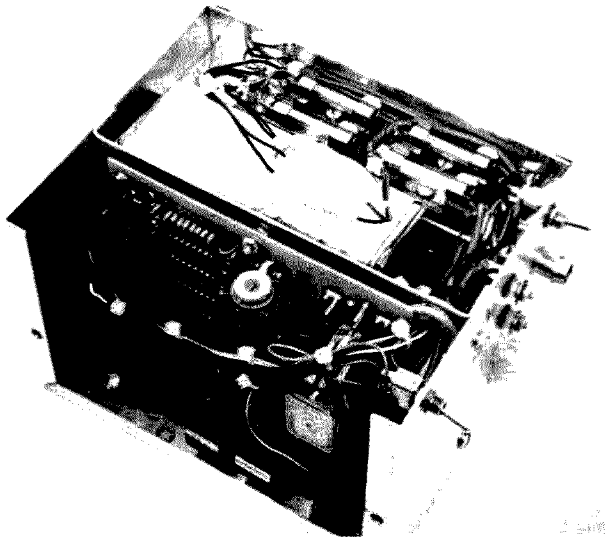
The tone encoder circuitry incorporates two reed oscillators and amplifiers for the page tones and one twin T oscillator for the identification tone. The output amplitude of each is fully adjustable for proper insertion to the transmitter. For reasons of frequency stability, reed encoders were used. These are able to withstand the wide temperature extremes found in automobiles without drifting off frequency. The basic design was from one encoder board, socket, and reed purchased from Communications Specialists, Box 153, Brea, California, and adapted for this use.

Since most pagers may come with reeds installed, it will be cheaper to match these reed frequencies to your encoder rather than buy new sets. From name plate information on the pager or the reeds themselves, you can determine the frequencies and order the proper reeds



Side views of alarm showing transmitter board installed.



The completed alarm with battery installed. Note battery plug and method of mounting control board.

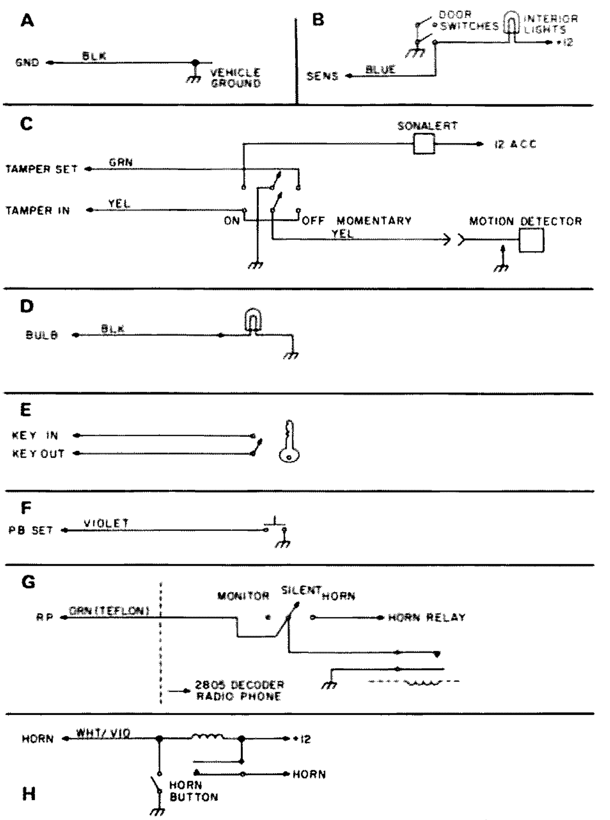


Fig. 4. Interface wiring, alarm to automobile. (c) Tamper set wiring. (d) Status lamp wiring. (e) Keyswitch wiring (operational). (f) Push switch set/reset wiring. (g) Radio page feature.

and sockets. Communications Specialists can supply either reeds, sockets, or complete encoders. If you don't have the reeds installed in the pager, choose any two tones you want or specify you want popular reeds, so that you can get new ones in the future at hamfests or surplus.

Another circuit centered around Q16 allows the tamper sensors to settle down after the car has been driven. Essentially, this circuit disconnects the motion sensors until they have stopped moving to prevent your pager from going wild every time you park your car. If Q8, the SCR, is turned on while the motion sensors are moving, Q7 will conduct through K3, an NC SPST relay in series with the motion sensors. Capacitor C32 smoothes the pulses from the motion detectors and keeps Q7 turned on until the motion has initially stopped. Q7 then turns off, and since there is no longer a load on the SCR, it no longer conducts. With relay coil K3 no longer energized, any further motion now made by the car will not turn Q16 on and will enable the tamper alarm circuitry.

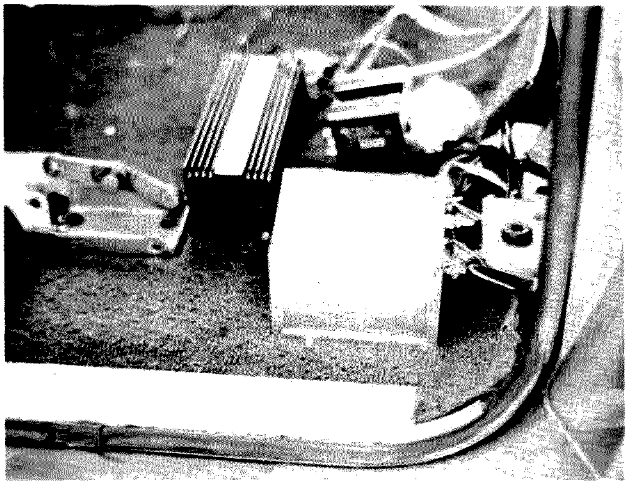
The A input is connected to the output of relay K4 of the alarm circuitry (Fig. 2). When this input is grounded to the vehicle frame, current flows through D22 and R9 to turn Q2 and K2 on. At the same time, current flows through R14 and D21 to Q6, keeping it on so that the identification tone will be steady rather than pulsing.

The vehicle alarm circuit is triggered only when sensors described above are triggered (door switches, mats, vibration sensors, etc.). This circuit is shown in Fig. 2. When the input marked "key" is at +12 volts, Q17 is biased on and grounds the R65-D31 combination which is essentially the base of Q19. If Q17 is turned off by grounding the sensor input momentarily, the collector goes high. Q18 turns on and C34 is charged through R65 and D31. With Q17's collector low again, current flows from C34 into the base of Q19, keeping it on for the length of time determined by R67 and R68. D31 prevents C34 from discharging back to ground through the now "on" Q17.

As C34 becomes discharged, Q18 turns off and K4 opens. Since C34 holds a residual charge and will therefore exhibit different time periods if a sensor is again triggered, R69 keeps C34 discharged through K4 while the alarm is off, thereby providing instant reset to whatever time delay has been set (2-3 min.).

K4 provides +12 volt and vehicle ground switching. This is a 4PDT relay rated at 10 Amps. Two sets of contacts are brought out to connectors to provide +12 volts directly to a Federal electronic siren, and two discrete switched grounds are available for the horn relay and the A input to the paging alarm.

Since it was desirable to have easy set/reset capability, a mechanical latching relay is used to arm the system. A push-button sets or resets the alarm and, with no physical switch position to tell if it is set or not, an indicator light is included. When the "key" input is connected through the latching relay to +12 volts, R61 turns on Q20. Initially Q19 is biased on by R60 and passes current to a bulb, keeping it lit. With Q20 on, however, Q19 is turned off and the light goes out,



The completed system installed under rear pull-up seat in car.

indicating the alarm is set.

One other circuit is on the board and is a specialized circuit for my own use. With an RCC phone in the car, it has become desirable to have some form of paging occur if someone calls. Since the equipment was present, it seemed easy enough to add a simple circuit to have the alarm call the paging receiver.

When an RCC operator decodes me, a decoder in the RCC radio provides a relay closure to ground. The output of this is tied to isolating relay K1, an SPST relay. This grounds K2, turning on the system and the regular page tones are sent. As explained before, the second page tone sets off the pager receiver's alert tone, which stays on as long as the second tone is transmitted. However, with Q1's emitter grounded by K1, when the base goes high, the collector inhibits the clock input to U2 so that the second page tone will stay on as long as the operator pages me, thereby triggering a continuous alert tone in the pager.

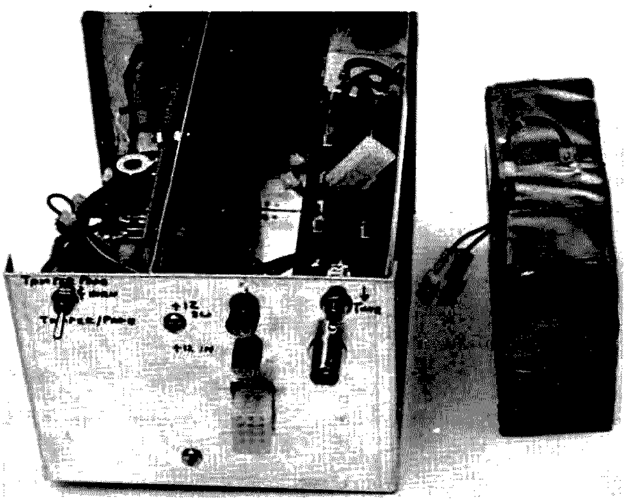
This portion of the circuit is useful if you have RCC or ham decoders, such as touch-tone or PL, which are activated when someone calls you.

We thus have three modes of operation for the paging alarm, identifiable by means of the types of tones out of the pager:

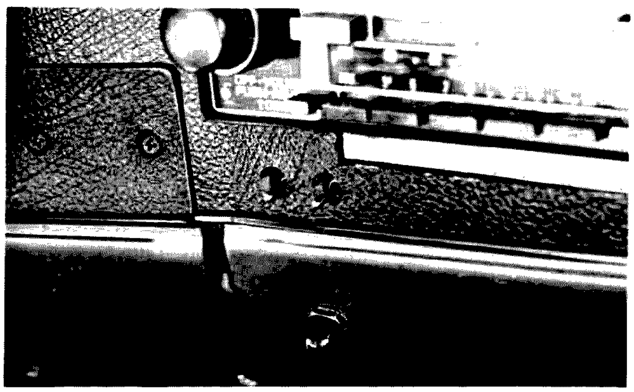
1. A pulsed tone after the alert — Someone is either tampering with the car or an object has hit it, possibly a truck.
2. A steady tone after the alert — Overt action has been taken and entry has been gained, or the above truck totaled your car.
3. A repeating alert signal only — You have just been called on one of the car radios.

Construction was in an LMB 6" x 5" x 4" minibox (#AMC 1007). Two subchassis were bent to fit within the box and used to hold the transmitter and circuit boards (see photos). The battery pack is in between the two. Use was made of Waldom PC card terminals for easy servicing. At each labeled input/output pad, Waldom pins (#R-62-3) were used. The connecting wires had crimp-on sockets (#0206 1103) and were routed to a Waldom plastic 15 circuit connector shell on the outside of the housing, mounted through into the battery compartment. Also located in the battery compartment is the VW headlight dimmer relay (P/N 803941589). This relay is a mechanical latching type so that a single momentary pulse to the coil will turn it on *or* off. One contact goes to the +12 fuse (Fig. 3) and the other goes to the "key in" on the PC board. A hidden push-button switch may then be used to turn the alarm on or off from anywhere outside the car, in addition to having a more cumbersome (and secure) key switch.

Also mounted through into the battery compartment



View of completed unit. Note battery pack and connectors.



The automobile installation. The light is "on" when the alarm is not set. Of the two switches, the left, when pushed down, sets the tamper delay. When in the up position, the tamper alarm is on. The switch on the right controls another circuit in the car.

Fig. 6(a). PC board.

above the Waldom connector shell are two #8 screws with fiber washers to insulate them from the chassis. A solder terminal is under each one. #14 wires are then soldered to these and go to the +12 input fuse and relay K4. These two terminals then pass the heavy current required by the siren.

The battery pack is a 15 volt, 1 Ah array made from 12 commercial 1 Ah 1.25 volt nicad cells. Since these were already available, I wired them together in series and potted them in casting plastic, using an aluminum foil pie pan bent into a mold. These had solder tabs, but the flashlight "C" size will work every well with the plastic battery holders, which may be easily obtained, although they will take up more space.

Other sources of 15 volt batteries are Motorola HT-220 (omni) or HT-200 batteries, usually available for $5.00 from hamfests. A contact arrangement will have to be made up for these. For those of you with Motorola HTs, this is the very thing to use because you can use your HT chargers to keep the batteries up.

The battery ratings should be at least 500 mAh and 1 Ah is best. The larger the battery rating, the more time you can go between charging.

Two switches are mounted on the box. One is S2 (Fig. 3), which allows me to tune the transmitter by turning on the carrier alone. It is an optional feature which is used when parked in crowded public areas, such as a summer bluegrass festival, or ham flea market, where people tend to sit or lean on the cars. If the motion sensor is set off with this switch on, the horn will blow until motion ceases. I had many scratch marks on one car I owned that was usually parked in an area where people used to wait for buses. They wore exposed key rings and would lean back or sit on the car, leaving many deep scratches. It's very hard to sit on the hood of a car when the horn is blowing.

The double-sided PC board has been laid out for small components. Tantalum capacitors were used wherever there was a potential temperature problem (such as in the timing circuits) and also because of their size. CK05 capacitors were used in other locations for bypass and noise padding. Other types can be used, but judiciously, to prevent variation in clock speed, deviation, etc., with temperature. Ceramic disc bypass capacitors can be used if they are the 25 volt size to fit the layout.

After the board has been completed, you will need an audio amplifier and a 10 to 15 volt source to check it out. Begin by setting all controls to their midrange. Attach the hot lead of the amplifier to the point marked "Audio," +15 volts to the "+15" input, and -15 volts to the "-15" input. Also, attach the ground lead of the amplifier to the "-15" input, and connect a clip lead to the +15 volt battery lead.

Using a VOM connected between -15 and the junction of R7 and D3, connect the free end of the clip lead to the "A" input. The VOM should indicate 6 to 7 volts, although higher readings are permissible. Next, move the probe to the junction of R8 and D4 and check for 12 volts here.

At the same time, as you connect the clip lead to the A

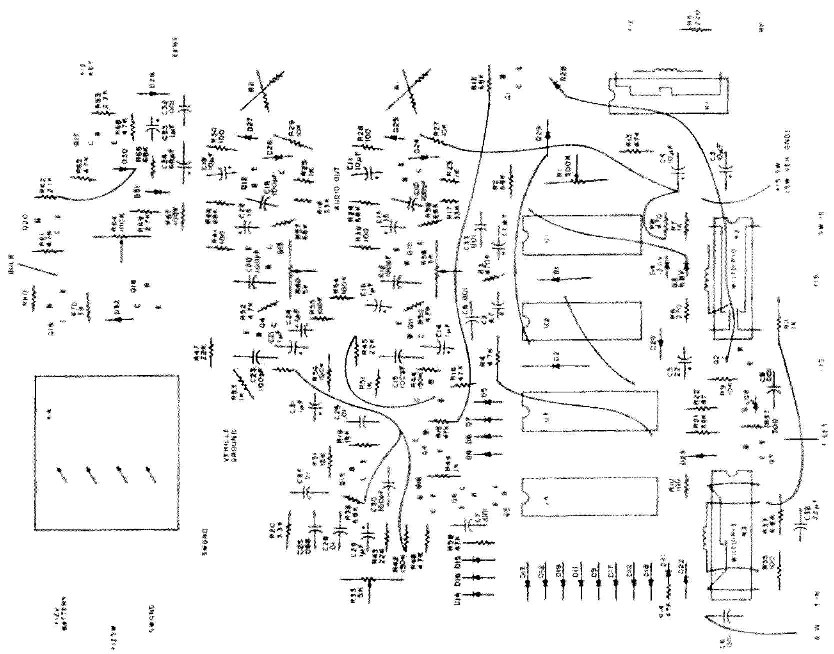


Fig. 6(b). Component layout.

input, you should hear a faint clicking noise from the audio amplifier and, after a short delay, you will hear the page tones followed by a steady alert tone. If this does not happen, the clock may be running too slow. Adjust pot R1, the clock adjustment, to a point at which something starts to happen with the tones.

Move the clip lead from the "A" input to the "T in" input and pulse it at a 2 or 4 pps rate by tapping the clip against the post. The voltage at R7 and D3 should be constant and the paging sequence should start as before. The only difference will be the alert tone, which will be pulsing rather than steady.

Now attach the clip lead to the "T in" post and adjust R1 for a one second 1st page tone or a ½ second on, ½ second off alert tone. Momentarily ground (-15) the "T set" input and insure that the voltage at R7 and D3 goes to zero until you *momentarily* release the clip lead from the "T-in" post. This indicates the tamper delay is working.

After the clock is adjusted and the circuit is performing correctly, check the radio call feature. Connect a clip lead between the "-15" input and "RP" input. Then connect another clip lead between the point marked "+12" (next to the "RP" input) and "+15". You should hear the two page tones; however, the second tone will stay on for as long as you have the clip leads attached.

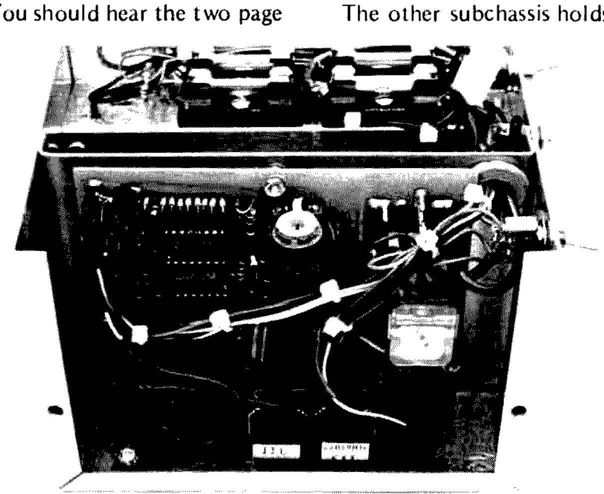
Assembly is simple and straightforward. The minibox bottom is divided into three equal parts by two subchassis bent to fit into the interior. Between the outside of the box and fastened to one subchassis is the control board. A hole punched into this subchassis allows the wires from the various pin connectors to be routed to their various destinations, mostly the 15 pin Waldom connector in the battery compartment.

The other subchassis holds the transmitter board between it and the other side of the minibox. Power and audio is fed to it through two feedthrough capacitors. You will note in the photographs that this subchassis is bent to provide a ledge holding the feedthrough caps and the fuse holders. One set of fuses are spares.

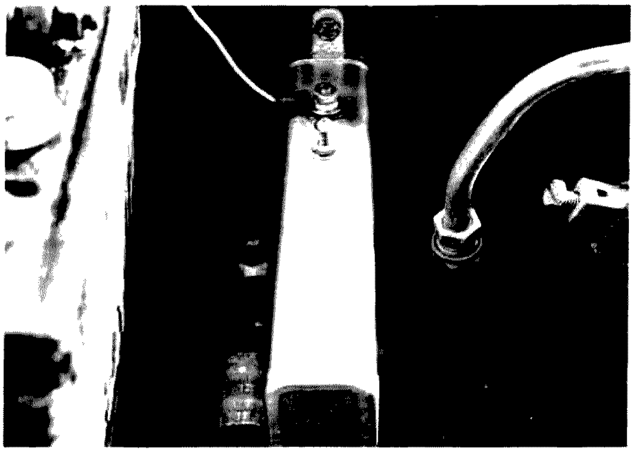
The antenna connector is mounted through to the transmitter compartment and a short piece (about 1/2 inch) of #18 stranded wire attaches to the antenna output of the transmitter board.

The battery compartment in the center holds the VW latching relay as well as the batteries. Depending on the size of the batteries you use, this may be otherwise empty with the batteries external to the box. If 12 "D" or "C" cells are used, the box will have to be larger. Another alternative is to use a large dry 15 volt "electronic equipment" battery, external to the box, making connections through the 15 pin connector.

After completion of the wiring and mechanical assembly, plug in the batteries with the 1 Amp fuse removed. Check with a milliammeter to insure that



View showing subchassis mounting.



One of the tamper sensors mounted in place in the engine compartment.

only a couple of microamps are being drawn with no inputs enabled. If all is well, install the fuses.

Tune the transmitter into a dummy load using the tune switch. At this point, you can check operation of the paging alarm if the pager is close by. About four seconds after connecting a clip lead from the chassis to the "A in" or "T in" inputs, the pager should emit its alert tone and sound the identification tone. If the circuit is left connected, after about 15 seconds the entire cycle will repeat itself.

Adjust the transmitter frequency trimmer to zero on the receiver (or vice versa) and adjust pots R38, R40, and R33 for proper audio. You will want to ideally be at ±5 kHz deviation, but if you don't have a deviation monitor, adjust for as close to the same audio level as a voice transmission and then check with a scope to see that all the tones are roughly the same. After making sure the unit is operational, it may be installed in the car.

A length of RG-58 cable was routed to the rear window and a metal clamp attached to the outer shield at the point where the cable emerged next to the window. The clamp was fastened to the window frame and the solid inner conductor stripped to a length of 20 inches. A piece of 50 lb. test nylon fishline held this wire taut and was routed to a small bracket mounted above the window. Then, with the aid of a through-line wattmeter, the wire was trimmed for lowest swr. The top was formed into a loop and the fishline stretched from there to a small spring fastened to the bracket. This method has kept the wire taut yet allowed for parcels to hit it without breaking the wire.

A key lock switch was installed on the body of the vehicle and is used in high risk areas, where the hidden push-button may not be as secure. The wires to this switch are routed to the 15 pin connector on the alarm chassis. See Fig. 4(e).

A momentary-on push-button switch was mounted in an easy-to-get-to yet unostentatious place on the outside of the car. In low risk areas, this switch is used exclusively as it allows quick and easy setting/unsetting of the alarm without the usual fumbling for the keys. The status bulb is located within the car on the dash. As mentioned before, when it is "on", the alarm is not set, and when it is out, the alarm is set. This prevents an occasional uninterested glance inside by passersby to change to an interested glance when they notice a green light glowing.

The switch for the tamper alarm set/reset function is also on the dashboard. This is a center off DPDT switch with a spring return in one position, and "on" in the other position. Depressing the switch momentarily, then quickly switching to the "on" position sets the tamper delay and readies the circuit so that when all preliminary motion has ceased, any further motion will sound the alarm.

The tamper sensors are made by Empire. Mine were obtained at a discount auto parts store. The term "discount" does not apply here because they cost $10.00 each and consist merely of a flat spring with a weight on one end. The whole thing is mounted in a small enclosure with the spring supported at one end. When the surface to which it is attached is moved, the weight causes a pendulum-like effect and brings the grounded spring into contact with an adjustable screw contact.

One characteristic of the motion is that due to the force against the screw contact, a small secondary or harmonic motion is imparted to the spring. As the car is driven to a halt and the alarm

set, the motion sensors gradually settle down. At some point, the motion of the spring will stop completely as the forces on it approach 180 degrees, and then it will start up again momentarily. The tamper delay circuitry senses this initial stop and unsets the delay, so that the tamper alarm will sound momentarily when the contacts close again. This is dependent to an extent on the sensitivity of the motion sensor, but serves as a handy check on the operation. Usually you are at your destination by the time the tamper circuitry arms itself, and you can tell if the beeper goes off whether or not you are too far away or if the unit is not working.

Additionally, these motion sensors are affected by temperature. If the sensitivity is set too close and the unit then heats up, such as after driving, it may be closed by the time you drive to your destination. If you then set the tamper delay, it will never release until the car cools off and the contacts release, which could take hours. The short beep you will usually hear is an indication that all is well.

Another check is made when you enter the vehicle. The action of opening a door and sitting on the seat should be enough to set off your beeper and the switch may then be turned off.

If you don't have your beeper with you one day, or other members of your family drive your car, a Sonalert hooked up as shown in Fig. 4(c) will remind them that you are transmitting if it sounds. It's very hard to be in the same car with a working Sonalert, so your transmitter and batteries will be preserved.

The entire alarm box can be mounted anywhere convenient, provided the two switches can be reached with a minimum of trouble. In my Chevrolet "Suburban," it is under the folding rear seat and near the door so that

servicing is easy and the switches are within easy reach. The individual wires from the mating 15 pin conductor are made up into a harness with wire ties and run to the front of the car, where connections are made to the various devices. With this harness, a #14 gauge wire is also run, which connects to the battery terminal at the starter solenoid. This wire connects to the "+12 input" in the box. Another length of #14 wire goes from the "switched +12" terminal on the box to the power switch on the electronic siren. The function switch on this siren is set to the "yelp" mode.

The transmitter to be used is left up to the user. My version, as said before, uses the GE Voice Commander II board. The VC II or VC III are okay, and HT-200 boards are available at hamfests very inexpensively. If you cannot locate any of these, VHF Engineering sells an inexpensive kit which is 12 volt negative ground. Since it will not work directly with the positive ground arrangement used with the circuit board, a small relay should be used to switch the transmitter on or off by placing the contacts in series with the vehicle battery or an auxiliary 12 volt battery.

The operating frequency of the transmitter and pager must be judiciously chosen. 146.94 is too popular, repeater input frequencies are frowned upon, and use of the commercial bands is a definite no. A choice could be 147.015, 146.475, or any other offbeat frequency. 146.94 was used in my first version with the HT-220 because I didn't want to "waste" a crystal position. When I switched to the pager, I kept this frequency at first; however, at hamfests .94 would be disrupted if someone leaned against the car and, at one, the special .94 repeater covered up my alarm signal completely.

At the time of writing, this new unit has been installed for two years and has exhibited complete reliability. The present car (bought two years ago) has been broken into 8 times. Six times the alarm went off as they opened the doors (I keep them unlocked to prevent breakage). Twice the tamper alarm went off in the middle of the night and as I hurriedly threw my clothes on, the pulsed tone changed to a steady tone and all hell broke loose outside. The thief in these cases had pried open a vent window without trying the door first, rolled the main window down, and opened the door by reaching inside. The motion circuitry detected the break-in and the alarm sensors detected the opening of a door.

Certain tamper signals have also alerted me to the fact that various things were happening. Once I caught a person trying to parallel park in front of me in a space too small for his car. He backed into me and tried to push my car back, a poor thing to do to an automatic transmission left in park. Two children climbing on my car with hard shoes on were asked to get off, and other miscellaneous unintentional nudgings and movements were detected as they happened.

The battery gets charged overnight every two months or so, but rarely needs it. I charge these 1 Ah cells at a steady 100 mA and temporarily use a standby battery for protection.

Another use for a device like this is to build it into a larger chassis with an antenna attached and with built-in motion detectors. The unit is then portable and may be simply placed on the seat or floor of a car, trailer, camper, etc., or hung from the door of a house. On a float, it can function as a wireless swimming pool alarm. Store owners with large, lit signs that get vandalized in the night can put one in the sign. One can be installed in a motorcycle, boat (with different sensors), private plane, etc. Since the pager receiver does not "hear" anything until after the two-tone page signal, it can be left on at all times, even while in the charger, and no irritating chit-chat or interference will ever be apparent. The range of the system is sufficient that a reliable alert will be heard to a radius of at least a mile. ■

Try Your KIM-1 On RTTY

-- CUL on your computer

KIM-1 is an eight bit microprocessor sold by MOS Technology,[1] which uses the MCS 6502 chip as its central processing unit (CPU). KIM stands for "Keyboard Input Monitor" and describes the software residing in read only memory (ROM) on the two 6530 multipurpose 40 pin chips on the KIM-1 board.

My reason for choosing the KIM-1 was price. The whole KIM computer, with cassette interface, keypad, TTY interface, LED readouts for address and data, costs under $250. For the beginner, there are some "bad" features about it, which I should mention.

To use the KIM-1, you must build your own power supply and cabinet. Also, the user manual and other documentation is oriented more toward the computer prototyper than to the hobbyist. Very few examples are given in the documentation supplied, and the user really has to dig into the machine to get to know it. Software has been very scarce, but, since the KIM-1 users group was formed,[2] more and more software is becoming available.

On the positive side, MOS Technology is making quite an inroad into their own software development. They will soon make a full math package available in ROM, as well as a complete editor-assembler (single pass type) in ROM also. To me, this is what is needed in the industry; by making the "firmware" a permanent part of the "hardware," you do not have to spend a large amount of time and trouble loading programs via cassette (which on KIM operates at about 135 baud).

The two programs included are not original. They are 6502 adaptations of programs which have already been published elsewhere for other type processors.[3,4] To use these programs, it is assumed you have, along with KIM-1, a working CRT terminal with a serial I/O Interface. I use an Infoton BASIC with a full-duplex 20 mA loop hooked to the KIM-1 20 mA loop terminals on the applications connector. I run my terminal at 4800 baud usually.

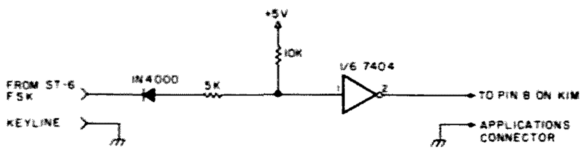

Fig. 1. Interface required to connect ST-6 FSK keyline (or any RS-232C level signal) to KIM-1.

The Baudot Receive Program

The first program was developed out of sheer necessity. Since I am interested in amateur radioteletype (RTTY), I needed a way to quiet things down around the shack while copying press broadcasts and amateur stations. My Model 28 KSR compact is very noisy, and, since KIM-1 and my CRT terminal make no noise, it sure is a lot easier on the nerves.

This is the listing for the Baudot (5 level) receive converter (or monitor), which is in use daily at this station. The FSK converter I use is the ST-6 built from the HAL kit.[5] The output of the ST-6, which I use to feed the computer, is the FSK line output, which is normally used to drive the FSK circuit of the amateur's transmitter. Irv Hoff, who designed the ST-6, in his wisdom chose the computer industry standard RS-232C levels for this output. This means that the output signal jumps in a discrete transition from -12 V to +12 V, which signify mark and space respectively. For more information on RTTY and the equipment you need to get started, see reference 6.

In order to make the ±12 V mark-space levels compatible with the 0 and +5 volt levels needed by KIM-1, you must first construct an "interface." This interface is very simple, and uses only four electronic components. See Fig. 1.

Unlike the KIM-1 monitor, which is completely self-adjusting in regard to baud rate, this monitor requires that you load two values into locations 0274 and 0283 for the various speeds you wish to copy. See Fig. 2. You will notice locations 0227 to 023F were left blank. If you wish to incorporate "unshift on space" in your monitor,

simply insert the unshift on space routine given at the end of the listing in the locations designated (locations 0220 to 022A). You would use the listing without the "unshift on space" for copying weather broadcasts and the listing with "unshift on space" for press and amateur copy.

To use this Baudot monitor, construct the interface and check the output with a voltmeter *before* hooking it up to pin 8 of the applications connector. You can use your receiver calibrator to supply the necessary mark and space signals to the converter, and the output of the interface should be at TTL levels. If you get the correct levels, hook the output of the interface to pin 8 of the applications connector. Next, load the program into the K1M-1 (hopefully via cassette), and make sure you loaded the correct delay constants for the speed you wish to copy from Fig. 2. Remember, most US press broadcasts use 66 wpm, so be sure to change the delay constants. The computer is not as forgiving as the Model 28, which *can* receive 66 wpm RTTY with 60 wpm gears.

CW Transmit Routine

This routine is basically a 6502 version of the program mentioned in reference 4. It really comes in handy on the CW net I check into several times weekly. If you would like to hear a sample of the CW this routine produces, tune in the Liberty Net on 3750 kHz at 8 pm CST on Wednesday and Saturday nights. I have used the same nomenclature used by Sewell, so you should have no trouble following the 6502 algorithm.

Location	60 wpm	66 wpm	75 wpm	100 wpm
0274	0B	0A	08	08
0283	15	14	11	0D

Fig. 2. Delay constants to be loaded into locations 0274 and 0283 for various RTTY speeds.

The most important difference between the 6800 CPU and the 6502 chip is the method used by each for indirect addressing. The 6800 uses a full 16 bit index register, while the 6502 uses two 8 bit index registers. Thus, when crossing a page boundary (256 bytes/page) with the 6502 in the indexed addressing mode, you must use quite a few tricks to keep from putting out an invalid address when on the first byte of the new page. The method I used can be seen at locations 001A through 0021, and 004A through 004F.

The buffer in this routine (ASDRIVER) is 512 bytes long, and includes all of pages 2 and 3 of my unexpanded KIM-1. Thus, since my terminal has 80 characters/line, I can store about 6½ lines of text before overrunning the buffer. 512 bytes will keep you from getting too long-winded. If your KIM is expanded and has more than the 1K of memory mine has, you can be as long-winded as you like. This routine will automatically cross the page boundaries for you (I pity the poor guy on the other end, though).

You must construct an interface from the TTL level output of pin 14 of the applications connector to your transmitter. Since I use the Heath SB-400 which has about +25 V on the CW keyline, this interface is a little more involved than the one for the RTTY interface described above. However, it uses the same 7404 chip as the RTTY interface, and both can be left connected together. See Fig. 3. If your transmitter will not work with this keyer, see the *TTL Cookbook* for other examples or the articles by Hoff in *RTTY Journal.* Don't forget to connect pin 14 of the 7404 chip to +5 volts and pin 7 to ground.

You will note in the comments for location 002B, "Is this a cursor left?" What this means is that my Infoton terminal has a separate cursor control keypad to control the cursor without affecting the display. Infoton uses the hex code "1A" to indicate a cursor left or backspace. Backspace in this routine is used to correct any mistakes while using the buffered routine. You hit backspace (in my case, "cursor left") and

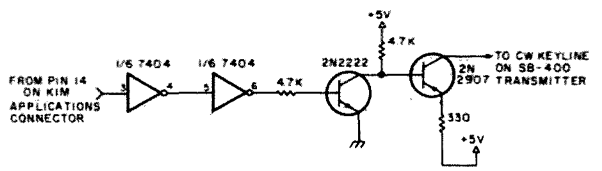

Fig. 3. Interface between KIM-1 and SB-400 transmitter. See text for source of other circuits covering other transmitters.

&	–	BT	-...-
+	–	KN	-.--.
=	–	AS	.-...

type right over the mistake. Thus the double-decrement of the x-pointer in locations 002F and 0030. If your terminal uses another code for backspace, simply insert it in location 002C. Notice locations 0000 and 0001 in the listing. These are labeled ELSPEED and CHRSPEED. These locations are for timing constants used in the delay routines by the timer, at locations 00CF and 00DF. For normal CW, location 0000 contains the speed you desire (a value of hex 30 = 20 wpm, hex 60 = 10 wpm, etc.), and location 0001 contains the spacing between individual characters, and should contain hex 03 (which means the spacing between characters will be equal to 3 dot lengths). Larger numbers in location 0000 give progressively slower CW speeds, and vice versa. When using the SINGLECH routine, location 0001 should contain hex 01. Notice that the buffered routine starts at location 0005 and the single character routine starts at location 0145. If you desire to switch from one to the other, you must stop KIM. In the KIM-1 user manual, the method for doing this is not made clear. You must load the NMI vector (the vector you get by pushing the stop key on the keypad) into locations 17FA and 17FB. Then, when you push the stop button, the NMI line is brought low and signals an interrupt to the 6502 chip. Internally the 6502 completes its present instruction and jumps to locations 17FA and 17FB for directions on where to go to service the interrupt. The program counter will then address the location contained in 17FA and 17FB. MOS Technology recommends loading 1C00 into this location. But, you must load them in reverse, with the low order byte first. Thus, remember to always load 00 into location 17FA and 1C in location 17FB. This is the first thing you should do when bringing up the computer.

There is another peculiarity of KIM which is not stressed enough in the documentation. This concerns the use of the flag status register at location 00F1 while using the cassette interface. Since the 6502 chip has a decimal mode of arithmetic operation, and since the cassette interface will only work in the binary mode of operation, you must *always* clear the decimal flag before any cassette load or dump operations. Simply load hex 00 into location 00F1 before using the cassette.

To use this CW routine, load your program into the computer, and be sure to load your code speed into locations 0000 and 0001. If you wish to use the buffered output, go to location 0005,

hit a "G", and type your message (up to 512 characters using the basic KIM). Do *not* hit any line feeds until you are ready to transmit, as this is the character which starts the transmit portion of the program. Let the terminal supply the returns and line feeds. If you make a mistake, hit backspace and type over it. When your message is complete and ready to transmit, simply hit a line feed, and you will hear some mighty fine CW going out. Fig. 4 lists some special keys used for CW characters having no ASCII equivalents.

To use the single character routine, start the program at location 0145. The character you type will be output immediately after each key is hit. This routine is a must for break-in operation.

In summary, both of these routines have been in use for several months at my QTH. I had considered writing a CW receive routine, but, as Wayne Green W2NSD/1 mentioned in his talk at the New Orleans Computerfest, most fists are so bad even the best algorithms cannot copy them unless the sender is using an electronic keyer. And, as he pointed out so well, CW is ten steps backward in technology and will remain so until hams get off their seats and write the FCC demanding the use of ASCII on the ham bands. ■

S.D. Sales Z-80 Review

-- quality at a good price

With the price of hobby computer equipment going from expensive to overpriced and, lately, to outrageous, I have been home brewing most of my computer equipment. This makes it more affordable, as the price of the components plus the cost of a wire-wrap Altair S-100 card is usually a small fraction of the price of the equivalent kit. I have designed and built a complete Altair S-100 bus computer for about $100-150 less CPU card. This computer has all the panel functions of a commercial machine, such as the IMSAI, and performs equally. It was originally designed to use the somewhat obsolete 8080 CPU card that was removed from my other computer when I changed over to a Z-80. However, as anyone who has ever used both chips can tell you, once you have used a Z-80 you will not be able to tolerate the poor instruction set and processing inefficiency of the 8080. About that time I saw an ad for the $149.95 Z-80 CPU card from S.D. Sales. It was fantastic and was at a price that was less than my first Z-80 card cost to build. Of course, the price of the Z-80 had dropped somewhat since I built my first card, but the price was still around the current cost of parts to build a card, so I ordered one.

Having built several microcomputer kits, and lived with poor documentation, poor quality boards, idiotic designs that were very hard to change, etc., I didn't really know what to expect at such a low price. But, past experience with S. D. Sales on parts orders had shown me that they were reputable, quick, and generally offered a good value with prime quality parts. This still did not completely prepare me for the surprise that I got when I opened the package.

The PC board was one of the best quality boards I have ever seen. Fully solder masked, high quality plating, plated through holes ... everything! The design was really superb – two 5 V regulators with heat sinks (most CPUs really need two as the current required for all the buffers really heats up one), heavy power buses with a fantastic ground plane, silver mica caps, precut, preformed resistors (most resistors and caps were precut, preformed, and ready to insert in the PC board), a very thick book on the design, software, and hardware differences between the Z-80 and 8080, complete instructions for assembly, and a Z-80 manual. The ICs were all prime quality with very recent date codes. All of the component values (part numbers) were screened exceptionally clearly on the component side of the board, and the IC numbers and component numbers are still visible after installing sockets (there were sockets provided for everything) and components.

The actual assembly of the board was one of the easiest and quickest assemblies of PC boards I've ever done. The instructions were excellent, and the preformed leads and clear screening made everything fall together. One or two resistor locations were somewhat obscure, as they did not wind up in the general numeric order of most of the parts and required a little searching. But there were only a couple of these, and they were solved after a few seconds of searching.

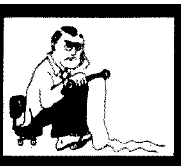
I popped the board into the computer and powered it up. Everything worked beautifully, the first time, and with no problems. I did have to make one minor modification to my VDM board (involving the bending of one pin on an IC) before I could initialize the screen. This was mentioned in the Z-80 manual that S. D. Sales provides (the kit manual), but I wanted to try it first to see if it was really necessary. They also mention a few modifications and changes (all very minor) to other boards to get them to work with the Z-80. This is necessary in the case of the VDM because of the timing difference between the Z-80 and 8080 (the Z-80 is in most cases faster). However, it works fine, and it was really thoughtful of S. D. Sales to point all of these differences out. (This is an example of the thorough and complete attention to detail and documentation that is typical of everything involved with the kit.) It is one of the truly fantastic bargains still available on the hobby microcomputer market today.

Speaking of fantastic bargains, S. D. Sales also makes a 4K low power memory board for the Altair S-100 bus that is an equal bargain, in that it has the same quality parts, is

equally well documented, easy to build, and costs less than the components to wire-wrap one. This is another well-designed, well-implemented piece of hardware. The board uses 4 regulators and runs very cool. Fast memory chips and good design allow super fast board access time. (The board has no provisions for wait states but works perfectly with a Z-80 CPU running at almost 3 MHz, which is far in excess of specs.) There are sockets for everything. Run to the nearest phone and order a dozen or so right away, before they come to their senses and raise the price to what it should be. At $89.95 you are robbing them blind.

The combination of the CPU and memory gives you the basis for a really super home brew computer with the addition of a panel, backplane and power supply. This will give you a complete machine, with a Z-80, 16K of reliable, low power STATIC memory, and full I/O for about the cost of a bare IMSAI or the same with video output capability for the cost (or slightly less) of an Altair (the case, panel, 8080 CPU and power supply and nothing else).

In case this review seems too good to be true, you might remember the early days of *73* when I used to review ham radio equipment. I never was overly kind to a manufacturer that didn't deserve it and told it like it was. I still feel the same today, and with the abundance of shoddy, overpriced computer equipment on the market (as well as a lot of very good equipment), these product reviews are an important guide as to what to buy or avoid. However, they should also be a useful guide, if honestly written, as to what is good and what is really a fantastic bargain. These boards from S. D. Sales definitely qualify for the category of fantastic bargain. ■



NEVER SAY DIE

EDITORIAL BY WAYNE GREEN

from page 15

been involved with, right from the start.

The above is not intended as bragging; it is to put what I am about to write into perspective. Note that there is no one involved with the ARRL or any other ham magazine with even a fraction of this background. I have been at the heart of amateur radio for a long time now, and I think I understand how the pieces of the puzzle fit together.

THE OVERALL PICTURE

Before we can adequately tackle an immediate problem, it is helpful to step back and take a long look at the whole situation. This keeps us from being too confused by the trees to see the forest.

Amateur radio exists because international allocations of frequencies have been set aside for it by the International Telecommunications Union (ITU), an international organizer of all radio frequencies and wire communications. The United States is a member nation of the ITU and has agreed to abide by the rules which this body makes.

At each ITU frequency conference, amateur radio has lost frequencies. Old-timers remember when 20 meters went from 14 to 15 MHz and 40 meters from 7 to 8 MHz, etc.

1947 – ATLANTIC CITY

At this ITU conference, the major European nations got together with the U.S. and screwed the smaller nations of the world out of major portions of the shortwave bands. Radio was still primitive in many of the smaller countries, and their representatives didn't realize how the world would change in the next few years. The ITU at this time was firmly under the control of the U.S.

1959 – GENEVA

When this ITU conference came along, I had been editor of *CQ Magazine* for four years. I was selected by the State Department as one of the official representatives of amateur radio, along with Huntoon of the ARRL. I had visited the ITU the previous year and gotten the inside story on what was in store for amateur radio at the '59 frequency conference . . . and it was a truly alarming story. When I found out what the positions were of some of the supposed "friendly" countries, I called the general manager of the ARRL, Budlong, and offered to put aside any differences between the two magazines in order to present a united front. Budlong, in blunt four letter words, said he didn't need any help from anyone. He personally had been running amateur radio for years and he would continue to run it . . . so go to hell.

When I arrived at Geneva a short while before the ITU conference was to begin, I was issued a five foot shelf of position papers to wade through. Each of the countries at the conference had proposed substantial changes in the frequency allocations in the 3-30 MHz band.
